CONVERSION FACTORS

Length

1 in. = 2.54 cm

1 m = 39.4 in. = 3.28 ft

1 mi = 5280 ft = 1609 m

1 km = 0.621 mi

1 angstrom (Å) = 10^{-10} m

1 light-year (ly) = 9.46×10^{15} m

Volume

1 liter = 1000 cm^3

1 gallon = 3.79 liters

Speed

1 mi/h = 1.61 km/h = 0.447 m/s

Mass

1 atomic mass unit (u) = 1.660×10^{-27} kg

(Earth exerts a 2.205-lb force on an object with 1 kg mass)

Force

1 lb = 4.45 N

Work and Energy

1 ft · lb = 1.356 N · m = 1.356 J

1 cal = 4.180 J

1 eV = 1.60×10^{-19} J

1 kWh = 3.60×10^{6} J

Power

1 W = 1 J/s = 0.738 ft · lb/s

1 hp (U.S.) = 746 W = 550 ft · lb/s

1 hp (metric) = 750 W

Pressure

1 atm = 1.01×10^{5} N/m^2 = 14.7 lb/in^2
= 760 mm Hg

1 Pa = 1 N/m^2

PHYSICAL CONSTANTS

Gravitational coefficient on Earth g	9.81 N/kg
Gravitational constant G	6.67×10^{-11} N · m^2/kg^2
Mass of Earth	5.97×10^{24} kg
Average radius of Earth	6.38×10^{6} m
Density of dry air (STP)	1.3 kg/m^3
Density of water (4 °C)	1000 kg/m^3
Avogadro's number N_A	6.02×10^{23} particles (g atom)
Boltzmann's constant k_B	1.38×10^{-23} J/K
Gas constant R	8.3 J/mol · K
Speed of sound in air (0°)	340 m/s
Coulomb's constant k_C	9.0×10^{9} N · m^2/C^2
Speed of light c	3.00×10^{8} m/s
Elementary charge e	1.60×10^{-19} C
Electron mass m_e	9.11×10^{-31} kg = 5.4858×10^{-4} u
Proton mass m_p	1.67×10^{-27} kg = 1.00727 u
Neutron mass m_n	1.67×10^{-27} kg = 1.00866 u
Planck's constant h	6.63×10^{-34} J · s

POWER OF TEN PREFIXES

Prefix	Abbreviation	Value
Tera	T	10^{12}
Giga	G	10^{9}
Mega	M	10^{6}

Help students learn physics by doing physics

Dear Colleague,

Welcome to the second edition of our textbook *College Physics: Explore and Apply* and its supporting materials (Mastering™ Physics, the *Active Learning Guide* (ALG), and our *Instructor's Guide*)—a coherent learning system that helps students **learn physics by doing physics**!

Experiments, experiments… Instead of being presented physics as a static set of established concepts and mathematical relations, students develop their own ideas just as physicists do: they *explore* and analyze **observational experiments**, identify patterns in the data, and propose explanations for the patterns. They then design **testing experiments** whose outcomes either confirm or contradict their explanations. Once tested, students *apply* explanations and relations for practical purposes and to problem solving.

A physics tool kit To build problem-solving skills and confidence, students master proven visual tools (representations such as motion diagrams and energy bar charts) that serve as bridges between words and abstract mathematics and that form the basis of our overarching problem-solving strategy. Our unique and varied problems and activities promote 21st-century competences such as evaluation and communication and reinforce our practical approach with photo, video, and data analysis and real-life situations.

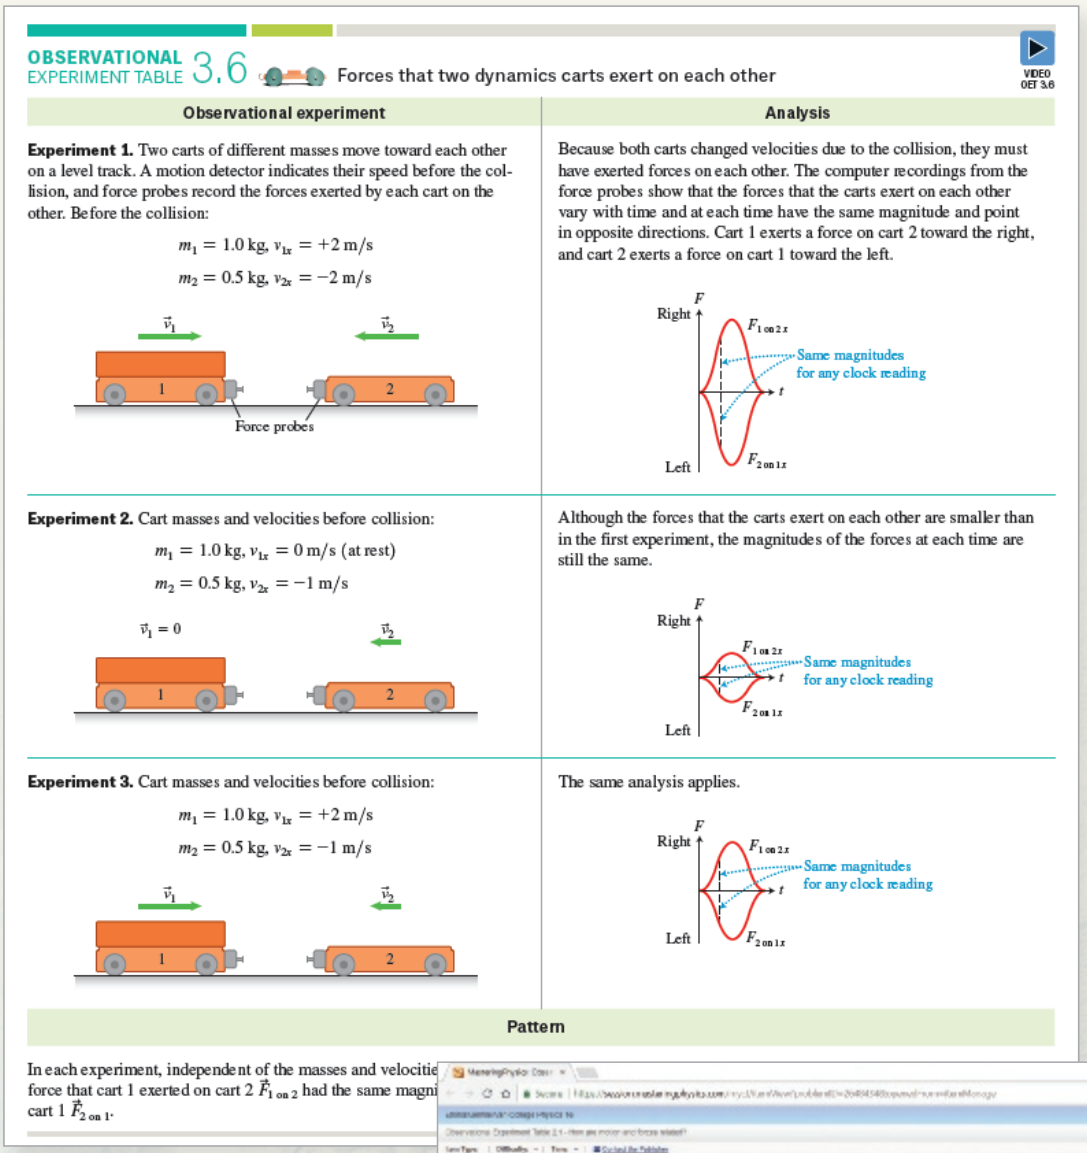
A flexible learning system Students can work collaboratively on ALG activities in class (lectures, labs, and problem-solving sessions) and then read the textbook at home and solve end-of-chapter problems, or they can read the text and do the activities using Mastering Physics at home, then come to class and discuss their ideas. However they study, students will see physics as a living thing, a process in which they can participate as equal partners.

Why a new edition? With a wealth of feedback from users of the first edition, our own ongoing experience and that of a gifted new co-author, and changes in the world in general and in education in particular, we embarked on this second edition in order to refine and strengthen our experiential learning system. Experiments are more focused and effective, our multiple-representation approach is expanded, topics have been added or moved to provide more flexibility, the writing, layout, and design are streamlined, and all the support materials are more tightly correlated to our approach and topics.

Working on this new edition has been hard work, but has enriched our lives as we've explored new ideas and applications. We hope that using our textbook will enrich the lives of your students!

Eugenia Etkina

Gorazd Planinsic



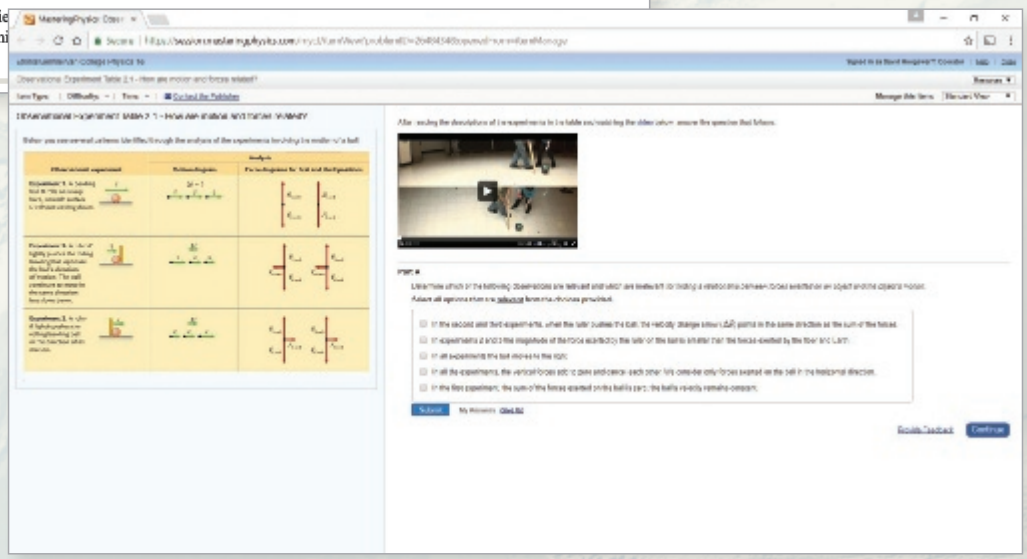
Alan Van Heuvelen

"This book made me think deeper and understand better."

—student at *Horry Georgetown Technical College*

PEARSON

A unique and active learning approach promotes deep and lasting

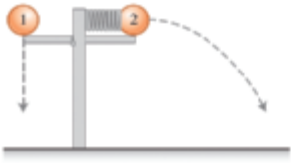


OBSERVATIONAL EXPERIMENT TABLE 3.6 Forces that two dynamics carts exert on each other

VIDEO OET 3.6

Observational experiment	Analysis
Experiment 1. Two carts of different masses move toward each other on a level track. A motion detector indicates their speed before the collision, and force probes record the forces exerted by each cart on the other. Before the collision: $m_1 = 1.0\ \text{kg}, v_{1x} = +2\ \text{m/s}$ $m_2 = 0.5\ \text{kg}, v_{2x} = -2\ \text{m/s}$ Force probes	Because both carts changed velocities due to the collision, they must have exerted forces on each other. The computer recordings from the force probes show that the forces that the carts exert on each other vary with time and at each time have the same magnitude and point in opposite directions. Cart 1 exerts a force on cart 2 toward the right, and cart 2 exerts a force on cart 1 toward the left. Right / Left; $F_{1\text{ on }2x}$; $F_{2\text{ on }1x}$; Same magnitudes for any clock reading
Experiment 2. Cart masses and velocities before collision: $m_1 = 1.0\ \text{kg}, v_{1x} = 0\ \text{m/s}$ (at rest) $m_2 = 0.5\ \text{kg}, v_{2x} = -1\ \text{m/s}$	Although the forces that the carts exert on each other are smaller than in the first experiment, the magnitudes of the forces at each time are still the same. Right / Left; $F_{1\text{ on }2x}$; $F_{2\text{ on }1x}$; Same magnitudes for any clock reading
Experiment 3. Cart masses and velocities before collision: $m_1 = 1.0\ \text{kg}, v_{1x} = +2\ \text{m/s}$ $m_2 = 0.5\ \text{kg}, v_{2x} = -1\ \text{m/s}$	The same analysis applies. Right / Left; $F_{1\text{ on }2x}$; $F_{2\text{ on }1x}$; Same magnitudes for any clock reading
Pattern	
In each experiment, independent of the masses and velocities, the force that cart 1 exerted on cart 2 $\vec{F}_{1\text{ on }2}$ had the same magnitude as the force that cart 2 exerted on cart 1 $\vec{F}_{2\text{ on }1}$.	

UPDATED! Observational Experiment Tables and Testing Experiment Tables: Students must make observations, analyze data, identify patterns, test hypotheses, and predict outcomes. Redesigned for clarity in the second edition, these tables encourage students to explore science through active discovery and critical thinking, constructing robust conceptual understanding.



NEW! Digitally Enhanced Experiment Tables now include embedded videos in the Pearson eText for an interactive experience. Accompanying questions are available in Mastering Physics to build skills essential to success in physics.

conceptual understanding of physics and the scientific process

TESTING EXPERIMENT TABLE 4.6 Testing the independence of horizontal and vertical motions

VIDEO TET4.6

Testing experiment	Prediction	Outcome
At time zero, ball 1 is dropped. Simultaneously, ball 2 is shot horizontally when a compressed spring is released. Which ball hits the surface first? 	Both balls start with zero initial vertical speed; thus their vertical motions are identical. Since we think that the vertical motion is independent of the horizontal motion, we predict that they will land at the same time.	When we try the experiment, the balls do land at the same time.

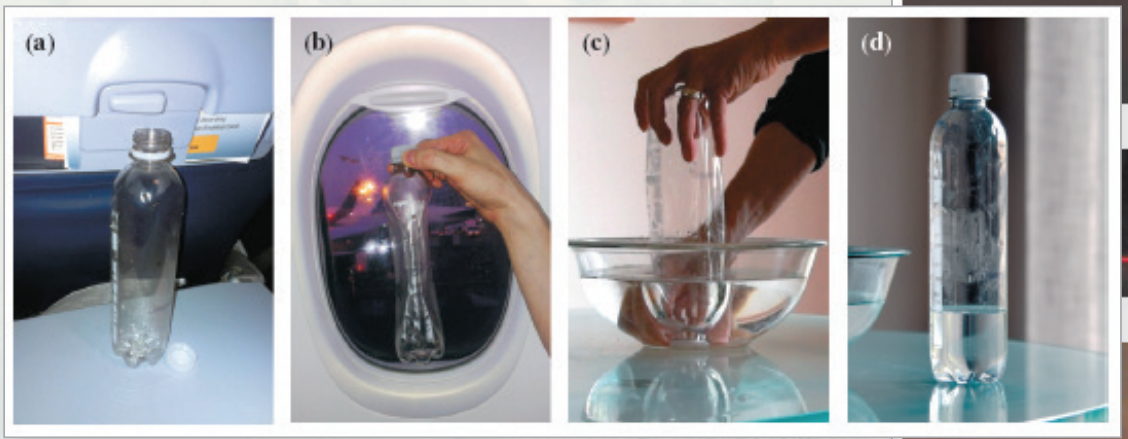
Conclusion

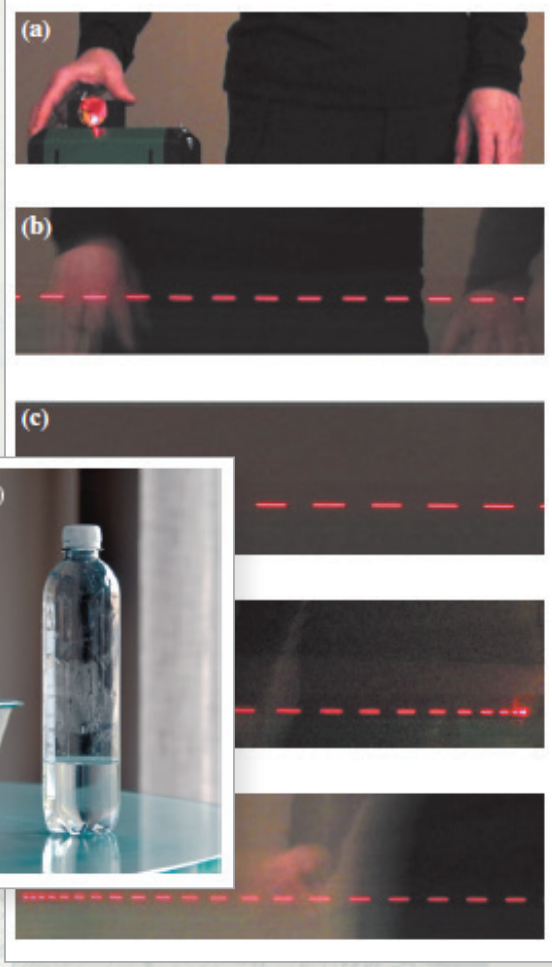
The outcome supports the hypothesis that horizontal and vertical motions are independent of each other.

"I like that the experiment tables... explain in detail why every step was important."

—student at *Mission College*

EXPANDED! Experiment videos and photos created by the authors enhance the active learning approach. Approximately 150 photos and 40 videos have been added to the textbook, as well as embedded in the Pearson eText, and scores more in the *Active Learning Guide* (ALG).





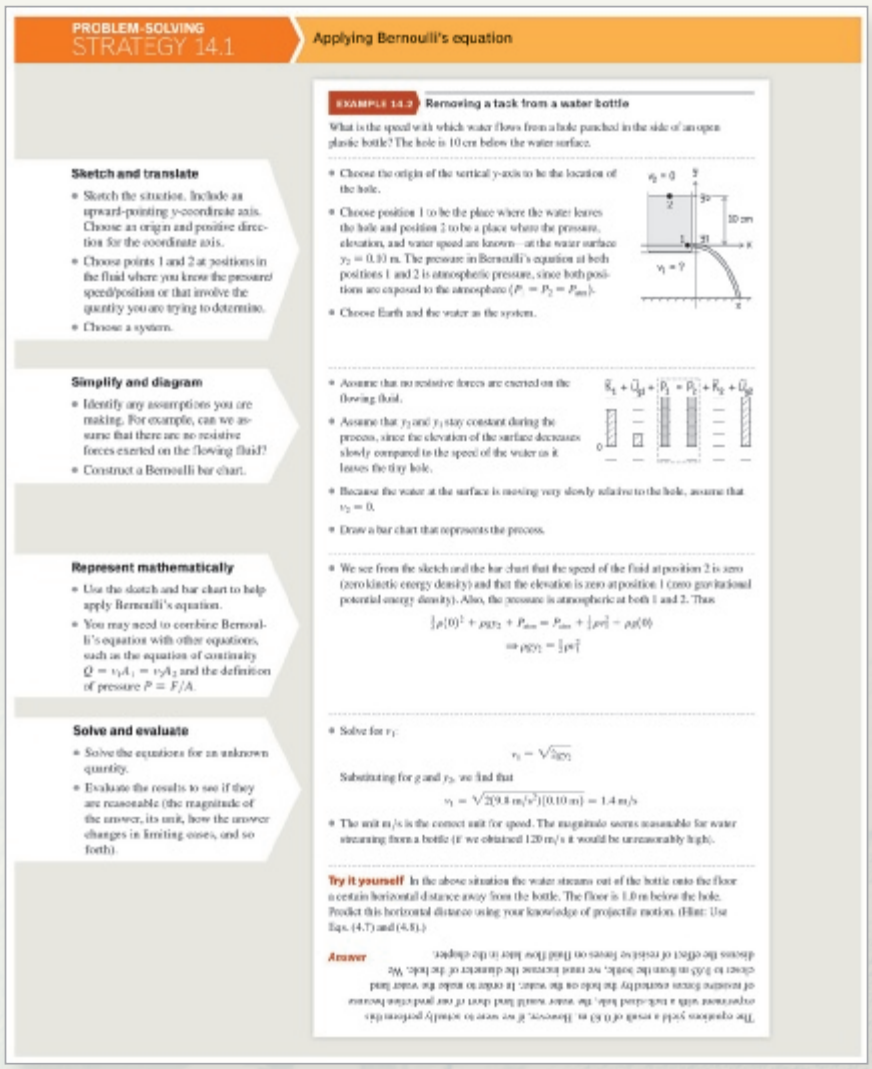


FIGURE 2.2 Long-exposure photographs of a moving cart with a blinking LED.

A wealth of practical and consistent guidance, examples, and opportunities

PROBLEM-SOLVING STRATEGY 14.1 Applying Bernoulli's equation

Sketch and translate

- Sketch the situation. Include an upward-pointing y-coordinate axis. Choose an origin and positive direction for the coordinate axis.
- Choose points 1 and 2 at positions in the fluid where you know the pressure/speed/position or that involve the quantity you are trying to determine.
- Choose a system.

Simplify and diagram

- Identify any assumptions you are making. For example, can we assume that there are no resistive forces exerted on the flowing fluid?
- Construct a Bernoulli bar chart.

Represent mathematically

- Use the sketch and bar chart to help apply Bernoulli's equation.
- You may need to combine Bernoulli's equation with other equations, such as the equation of continuity $Q = v_1A_1 = v_2A_2$ and the definition of pressure $P = F/A$.

Solve and evaluate

- Solve the equations for an unknown quantity.
- Evaluate the results to see if they are reasonable (the magnitude of the answer, its unit, how the answer changes in limiting cases, and so forth).

EXAMPLE 14.2 Removing a task from a water bottle

What is the speed with which water flows from a hole punched in the side of an open plastic bottle? The hole is 10 cm below the water surface.

- Choose the origin of the vertical y-axis to be the location of the hole.
- Choose position 1 to be the place where the water leaves the hole and position 2 to be a place where the pressure, elevation, and water speed are known—at the water surface $y_2 = 0.10$ m. The pressure in Bernoulli's equation at both positions 1 and 2 is atmospheric pressure, since both positions are exposed to the atmosphere ($P_1 = P_2 = P_{atm}$).
- Choose Earth and the water as the system.

- Assume that no resistive forces are exerted on the flowing fluid.
- Assume that y_2 and y_1 stay constant during the process, since the elevation of the surface decreases slowly compared to the speed of the water as it leaves the tiny hole.
- Because the water at the surface is moving very slowly relative to the hole, assume that $v_2 = 0$.
- Draw a bar chart that represents the process.

- We see from the sketch and the bar chart that the speed of the fluid at position 2 is zero (zero kinetic energy density) and that the elevation is zero at position 1 (zero gravitational potential energy density). Also, the pressure is atmospheric at both 1 and 2. Thus

$$\tfrac{1}{2}\rho(0)^2 + \rho g y_2 + P_{atm} = P_{atm} + \tfrac{1}{2}\rho v_1^2 + \rho g(0)$$
$$\Rightarrow \rho g y_2 = \tfrac{1}{2}\rho v_1^2$$

- Solve for v_1:

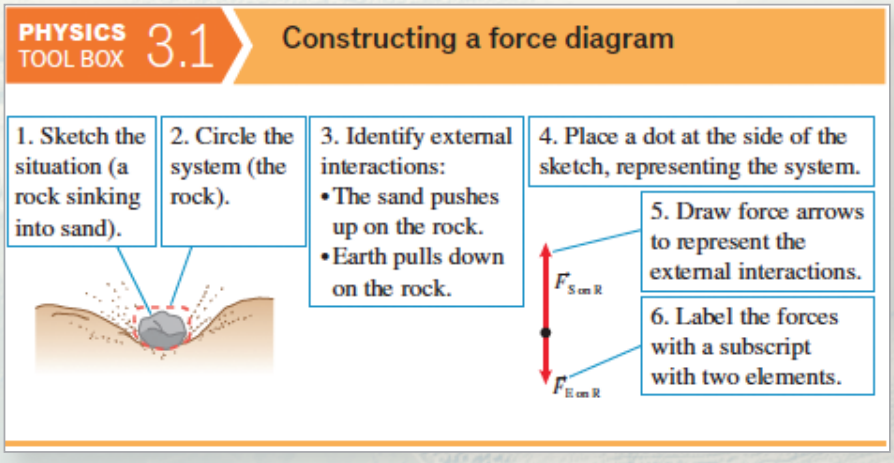
$$v_1 = \sqrt{2gy_2}$$

Substituting for g and y_2, we find that

$$v_1 = \sqrt{2(9.8\ \text{m/s}^2)(0.10\ \text{m})} = 1.4\ \text{m/s}$$

- The unit m/s is the correct unit for speed. The magnitude seems reasonable for water streaming from a bottle (if we obtained 120 m/s it would be unreasonably high).

Try it yourself In the above situation the water streams out of the bottle onto the floor a certain horizontal distance away from the bottle. The floor is 1.0 m below the hole. Predict this horizontal distance using your knowledge of projectile motion. (Hint: Use Eqs. (4.7) and (4.8).)



Answer The opposite [illegible] 0.63 m. However, if we were to initially pressurize the container with a tube-fed hole, the water would land short of our prediction because of resistive force exerted by the hole on the water. In order to make the water land closer to 0.63 m from the bottle, we must increase the diameter of the hole. We discuss the effect of resistive forces on fluid flow later in the chapter.

A four-step problem-solving approach in worked examples consistently uses multiple representations to teach students how to solve complex physics problems. Students follow the steps of **Sketch & Translate, Simplify & Diagram, Represent Mathematically, Solve & Evaluate** to translate a problem statement into the language of physics, sketch and diagram the problem, represent it mathematically, solve the problem, and evaluate the result.

Physics Tool Boxes focus on a particular skill, such as drawing a motion diagram, force diagram, or work-energy bar chart, to help students master the key tools they will need to utilize throughout the course to analyze physics processes and solve problems, bridging real phenomena and mathematics.

"It made me excited to learn physics! It has a systematic and easy-to-understand method for solving problems."

—student at *State University of West Georgia*

PHYSICS TOOL BOX 3.1 Constructing a force diagram

1. Sketch the situation (a rock sinking into sand).
2. Circle the system (the rock).
3. Identify external interactions:
   - The sand pushes up on the rock.
   - Earth pulls down on the rock.
4. Place a dot at the side of the sketch, representing the system.
5. Draw force arrows to represent the external interactions.
6. Label the forces with a subscript with two elements.

$F_{S\text{ on }R}$

$F_{E\text{ on }R}$

for practice help develop confidence and higher-level reasoning skills

56. * A frog jumps at an angle 30° above the horizontal. The origin of the coordinate system is at the point where the frog leaves the ground. Complete Table P4.55 by drawing check marks in the cells that correctly connect the quantities in the first column that describe the motion of the frog and the descriptions of what is happening to these quantities while the frog is moving. Consider the frog as a point-like object and assume that the resistive force exerted by the air is negligible.

TABLE P4.55

Physical quantity	Remains constant	Is changing	Increases only	Decreases only	Increases, then decreases	Decreases, then increases
x-coordinate magnitude						
y-coordinate magnitude						
Direction of velocity						
Magnitude of velocity						
Direction of acceleration						
Magnitude of acceleration						

29. * Your friend Devin has to solve the following problem: "You have a spring with spring constant k. You compress it by distance x and use it to shoot a steel ball of mass m into a sponge of mass M. After the collision, the ball and the sponge move a distance s along a rough surface and stop (see Figure P7.29). The coefficient of friction between the sponge and the surface is μ. Derive an expression that shows how the distance s depends on relevant physical quantities."

FIGURE P7.29

Devin derived the following equation:

$$s = \frac{kmx^2}{2(m+M)^2 g\mu}$$

Without deriving it, evaluate the equation that
reasonable? How do you know?

59. * Jeff and Natalie notice that a rubber balloon, which is first in a warm room, shrinks when they take it into the garden on a cold winter day. They propose two different explanations for the observed phenomenon: (a) the balloon is slowly leaking; (b) the balloon shrinks due to decreased temperature while the pressure in the balloon remains constant (isobaric compression). In order to test their proposed explanations, Jeff and Natalie perform three consecutive experiments: they measure the volume of the balloon and the temperature of the air near the balloon (1) in the room, (2) in the garden, and (3) again in the room. Their measurements, including uncertainties, are presented in the table below.

Exp. #	Location	Temperature	Volume of the balloon
1	Room	26.2 °C ± 0.1 °C	7500 cm³ ± 400 cm³
2	Garden	−15.3 °C ± 0.1 °C	6400 cm³ ± 400 cm³
3	Room	26.2 °C ± 0.1 °C	7300 cm³ ± 400 cm³

Based on the data, can Jeff and Natalie reject any of their hypotheses? Explain. Make sure you include uncertainties in your answer.

NEW! Problem types include multiple choice with multiple correct answers, find-a-pattern in data presented in a video or a table, ranking tasks, evaluate statements/claims/explanations/measuring procedures, evaluate solutions, design a device or a procedure that meets given criteria, and linearization problems, promoting critical thinking and deeper understanding.

"It helps break down the problems, which makes them look less daunting when compared to paragraphs of explanations. It is very straightforward."

—student at *Case Western Reserve University*

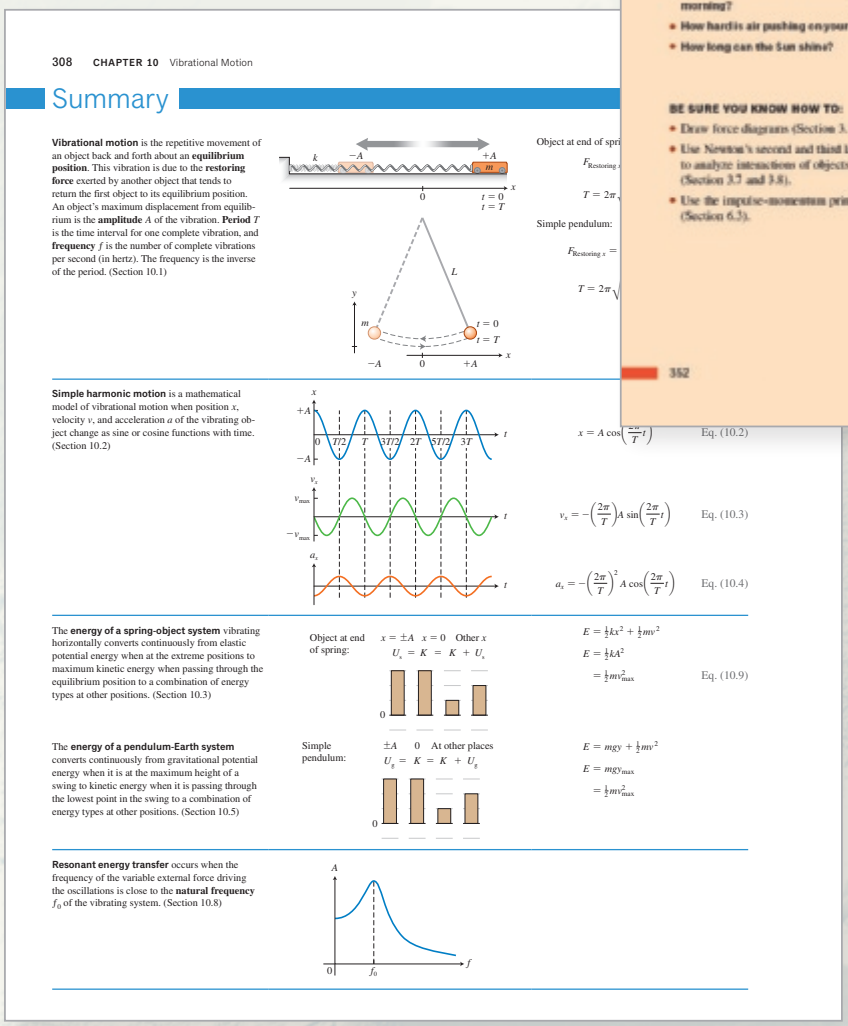
Pedagogically driven design and content changes

NEW! A fresh and modern design with a more transparent hierarchy of features and navigation structure, as well as an engaging chapter opener page and streamlined chapter summary, result in a more user-friendly resource, both for learning and for reference.

12

Gases

- Why does a plastic bottle left in a car overnight look crushed on a chilly morning?
- How hard is air pushing on your body?
- How long can the Sun shine?



When you inflate the tires of your bicycle in a warm basement in winter, they tend to look a bit flat when you take the bike outside. The same thing happens to a basketball—you need to pump it up before playing outside on a cold day. An empty plastic bottle left in a car looks crushed on a chilly morning. What do all these phenomena have in common, and how do we explain them?

BE SURE YOU KNOW HOW TO:

- Draw force diagrams (Section 3.1).
- Use Newton's second and third laws to analyze interactions of objects (Section 3.7 and 3.8).
- Use the impulse-momentum principle (Section 6.3).

IN CHAPTER 11, we learned that sound propagates due to the compression and decompression of air. But what exactly is being compressed? To answer this question and the ones above, we need to investigate what makes up a gas and how certain properties of gases can change.

352

308 CHAPTER 10 Vibrational Motion

Summary

Vibrational motion is the repetitive movement of an object back and forth about an **equilibrium position**. This vibration is due to the **restoring force** exerted by another object that tends to return the first object to its equilibrium position. An object's maximum displacement from equilibrium is the **amplitude** A of the vibration. **Period** T is the time interval for one complete vibration, and **frequency** f is the number of complete vibrations per second (in hertz). The frequency is the inverse of the period. (Section 10.1)

Simple harmonic motion is a mathematical model of vibrational motion when position x, velocity v, and acceleration a of the vibrating object change as sine or cosine functions with time. (Section 10.2)

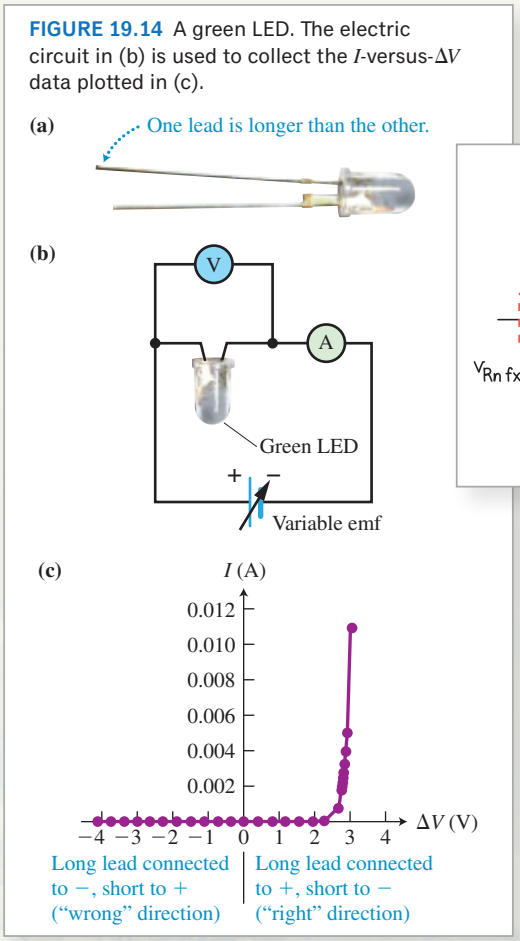
$$x = A\cos\left(\frac{2\pi}{T}t\right) \quad \text{Eq. (10.2)}$$

$$v_x = -\left(\frac{2\pi}{T}\right)A\sin\left(\frac{2\pi}{T}t\right) \quad \text{Eq. (10.3)}$$

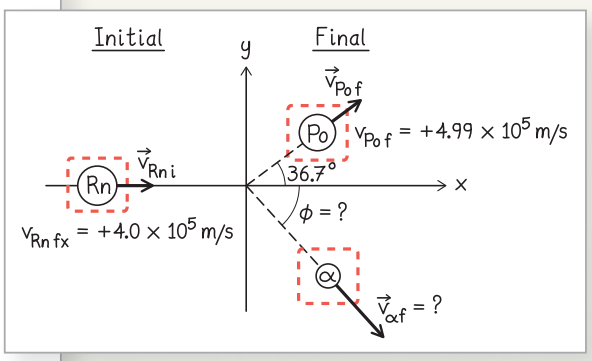
$$a_x = -\left(\frac{2\pi}{T}\right)^2 A\cos\left(\frac{2\pi}{T}t\right) \quad \text{Eq. (10.4)}$$

The **energy of a spring-object system** vibrating horizontally converts continuously from elastic potential energy when at the extreme positions to maximum kinetic energy when passing through the equilibrium position to a combination of energy types at other positions. (Section 10.3)

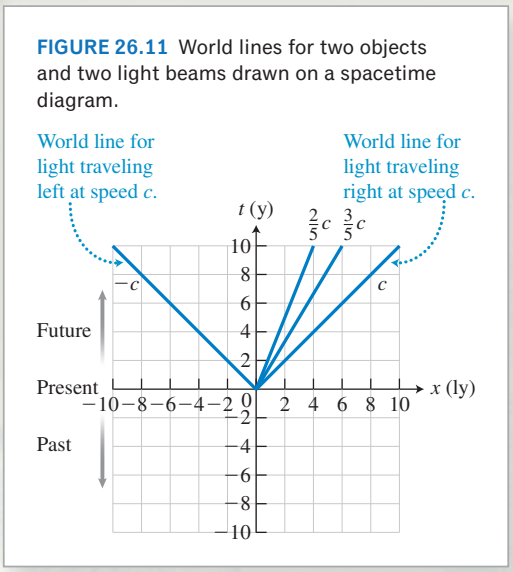
$$E = \tfrac{1}{2}kx^2 + \tfrac{1}{2}mv^2$$
$$E = \tfrac{1}{2}kA^2$$
$$= \tfrac{1}{2}mv_{max}^2 \quad \text{Eq. (10.9)}$$



The **energy of a pendulum-Earth system** converts continuously from gravitational potential energy when it is at the maximum height of a swing to kinetic energy when it is passing through the lowest point in the swing to a combination of energy types at other positions. (Section 10.5)

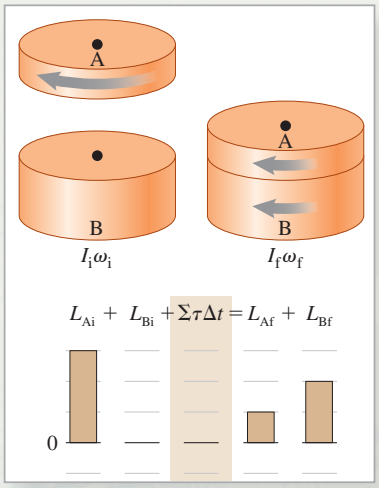


$$E = mgy + \tfrac{1}{2}mv^2$$
$$E = mgy_{max}$$
$$= \tfrac{1}{2}mv_{max}^2$$



Resonant energy transfer occurs when the frequency of the variable external force driving the oscillations is close to the **natural frequency** f_0 of the vibrating system. (Section 10.8)

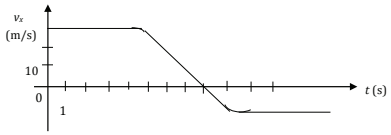
REVISED! Streamlined text, layout, and figures throughout the book enhance the focus on central themes and topics, eliminating extraneous detail, resulting in **over 150 fewer pages** than the first edition and allowing students to study more efficiently.



enhance ease of use for students and instructors alike

NEW, REVISED, and EXPANDED! Topics include capacitors, AC circuits, LEDs, friction, 2-D collisions, energy, bar charts for rotational momentum and nuclear energy, ideal gas processes, thermodynamic engines, semiconductors, velocity selectors, and spacetime diagrams in special relativity.

NEW! Integration of vector arithmetic into early chapters helps students develop vector-related skills in the context of learning physics. **Earlier placement of waves and oscillations** allows instructors to teach these topics with mechanics if preferred. Coverage with optics is also possible.



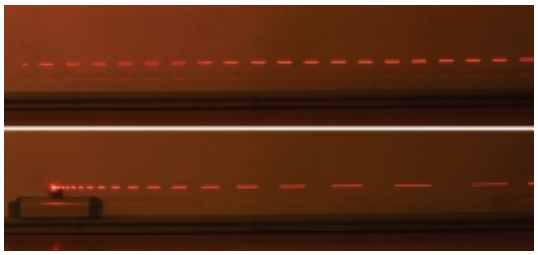
A flexible learning system adapts to any method of instruction

2.9.9 Evaluate the solution

Class: *Equipment per group: whiteboard and markers*

Discuss with your group: Identify any errors in the proposed solution to the following problem and provide a corrected solution if there are errors.

Problem: Use the graphical representation of motion to determine how far the object travels until it stops.



Proposed solution The object was at rest for about 5 seconds, then started moving in the negative direction and stopped after about 9 seconds. During this time its position changed from 30 m to – 10 m, so the total distance that it traveled was 40 m.

2.9.10 Observe and analyze

Class: *Equipment per group: whiteboard and markers*

Collaborate together with your group to figure this out: The figure below shows long exposure photos of two experiments with a blinking LED that was fixed on a moving cart. In both cases the cart was moving from right to left. The duration of the ON and OFF time for LED is 154 ms and the length of the cart is 17 cm. a) Specify the coordinate system and draw a qualitative velocity-time graph for the motion of the cart in both experiments; b) estimate the speed of the cart in the first experiment. Both photos were obtained from the same spot and with the same settings. Indicate any assumptions that you made.

Etkina, Brookes, Planinsic, Van Heuvelen COLLEGE PHYSICS *Active Learning Guide,* 2/e © 2019 Pearson Education, Inc.

REVISED! The **Active Learning Guide** aligns with the textbook's chapters and supplements the knowledge-building approach of the textbook with activities that provide opportunities for further observation, testing, sketching, and analysis as well as collaboration, scientific reasoning, and argumentation. The *Active Learning Guide* can be used in class for individual or group work or assigned as homework and is now better integrated with the text. Now available via download in the Mastering Instructor Resource Center and customizable in print form via Pearson Collections.

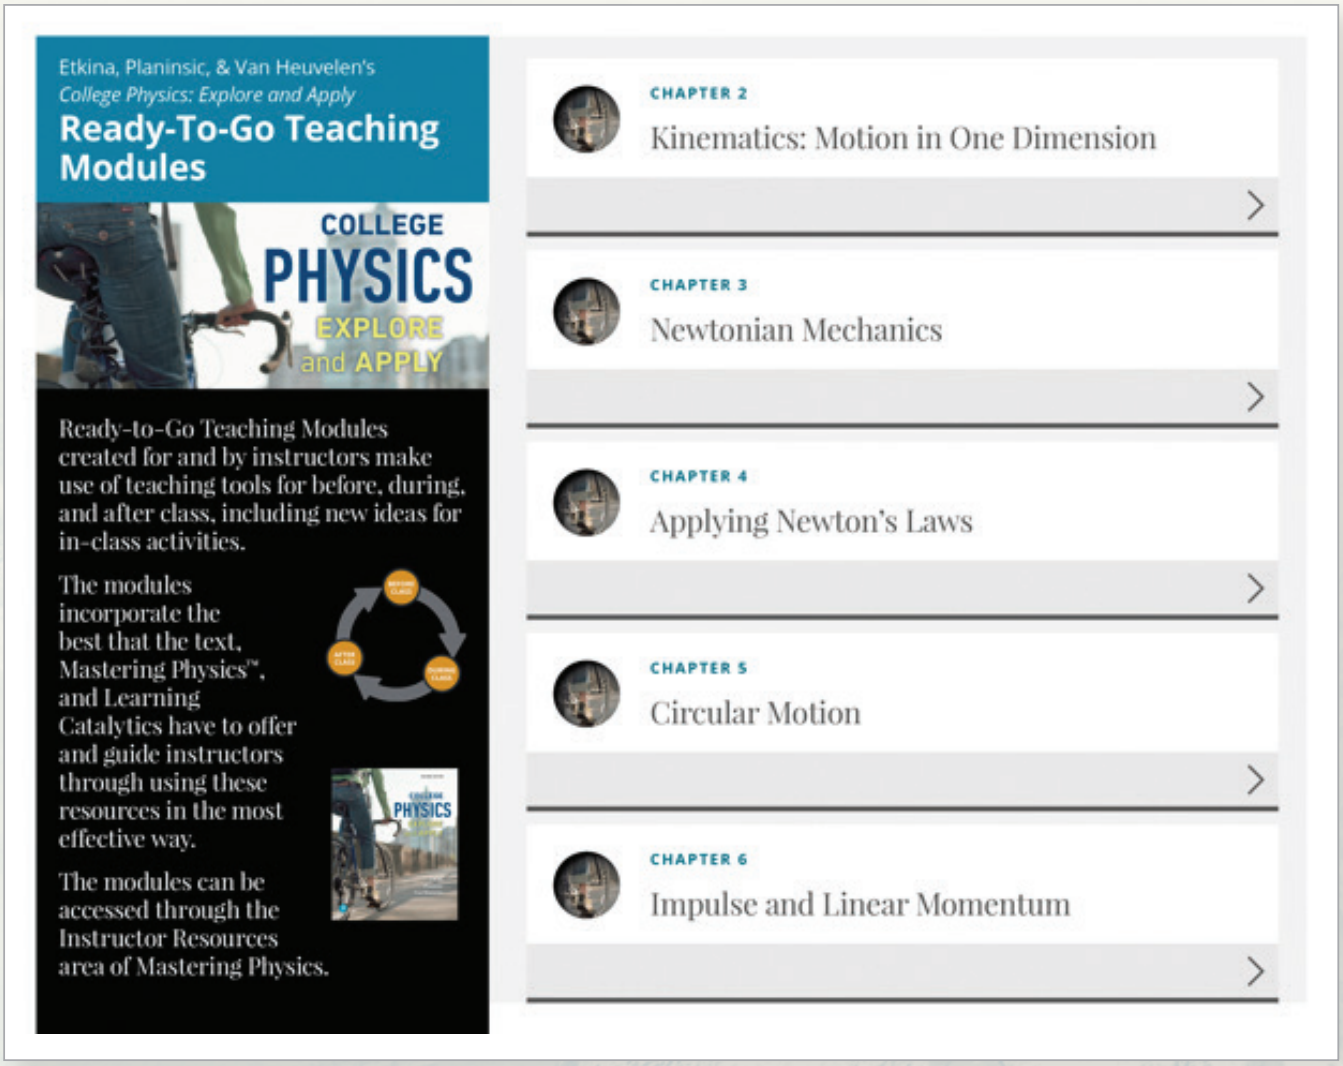
2

Kinematics: Motion in One Dimension

In Chapter 2, students will learn to describe motion using sketches, motion diagrams, graphs, and algebraic equations. The chapter subject matter is broken into four parts:

I. *What is motion and how do we describe it qualitatively?*
II. *Some of the quantities used to describe motion and a graphical description of motion*
III. *Use of the above to describe constant velocity and constant acceleration motion*
IV. *Developing and using the skills needed to analyze motion in real processes*

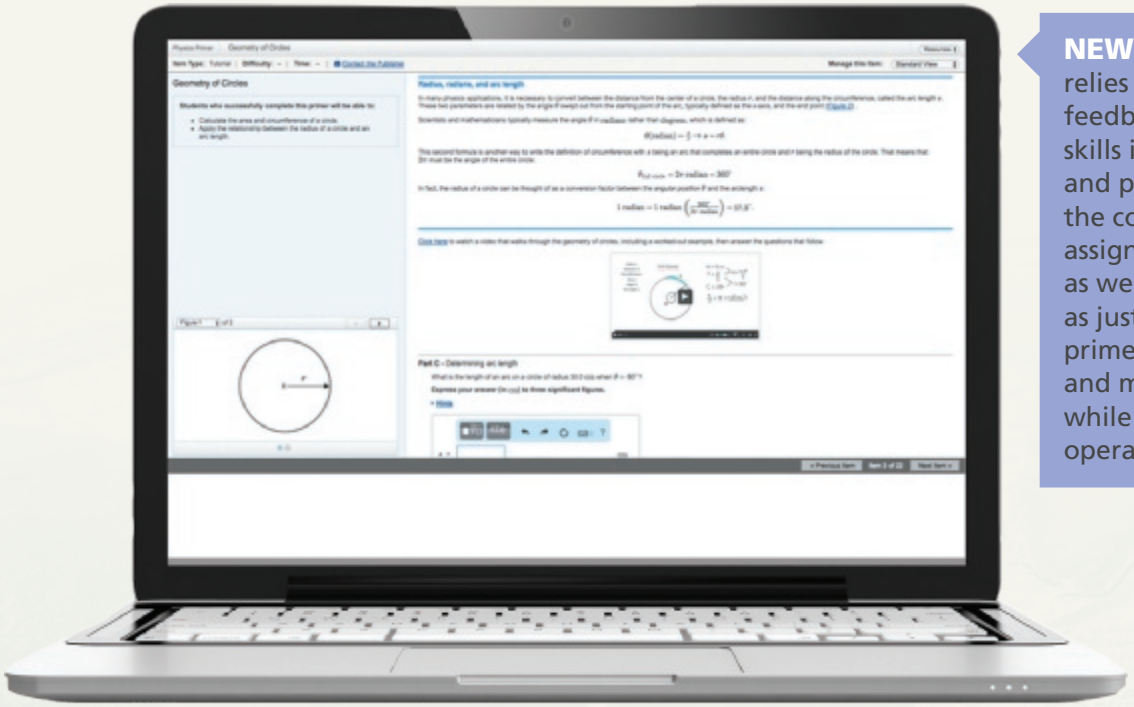
For each part, we provide examples of activities that can be used in the classroom, brief discussions of why we introduce the content in a particular order and use of these activities to support the learning, and common student difficulties.



Chapter subject matter	Related textbook section	ALG activities	End-of-chapter questions and problems	Videos
What is motion and how do we describe it qualitatively?	2.1, 2.2	2.1.1–2.1.6, 2.2.1–2.2.4	Problems 1, 3	OET 2.1

> *"It is much easier to understand a concept when you can see it in action, and not just read it."*
>
> —student at *San Antonio College*

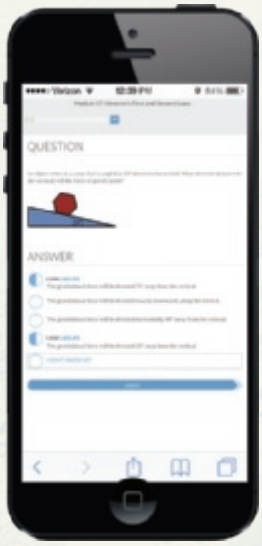
The **Instructor's Guide** provides key pedagogical principles of the textbook and elaborates on the implementation of the methodology used in the textbook, providing guidance on how to integrate the approach into your course.



and provides tools for easy implementation

NEW! Ready-to-Go Teaching Modules created for and by instructors make use of teaching tools for before, during, and after class, including new ideas for in-class activities. The modules incorporate the best that the text, Mastering Physics, and Learning Catalytics have to offer and guide instructors through using these resources in the most effective way. The modules can be accessed through the Instructor Resources area of Mastering Physics and as pre-built, customizable assignments.

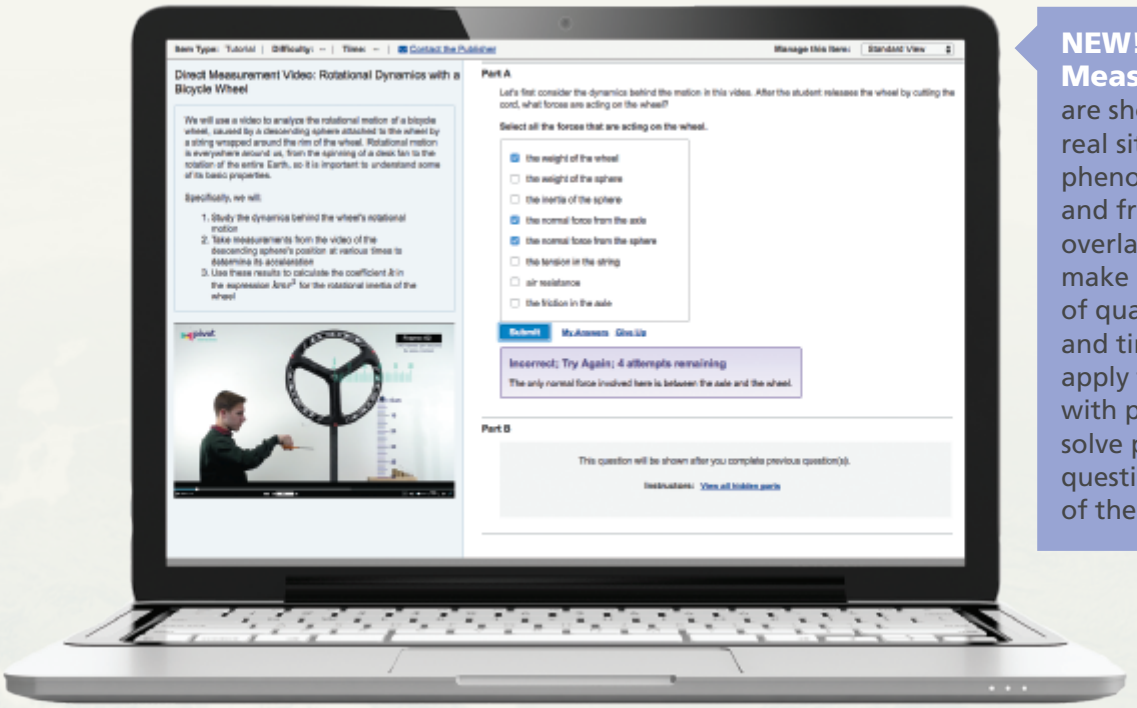
Mastering Physics



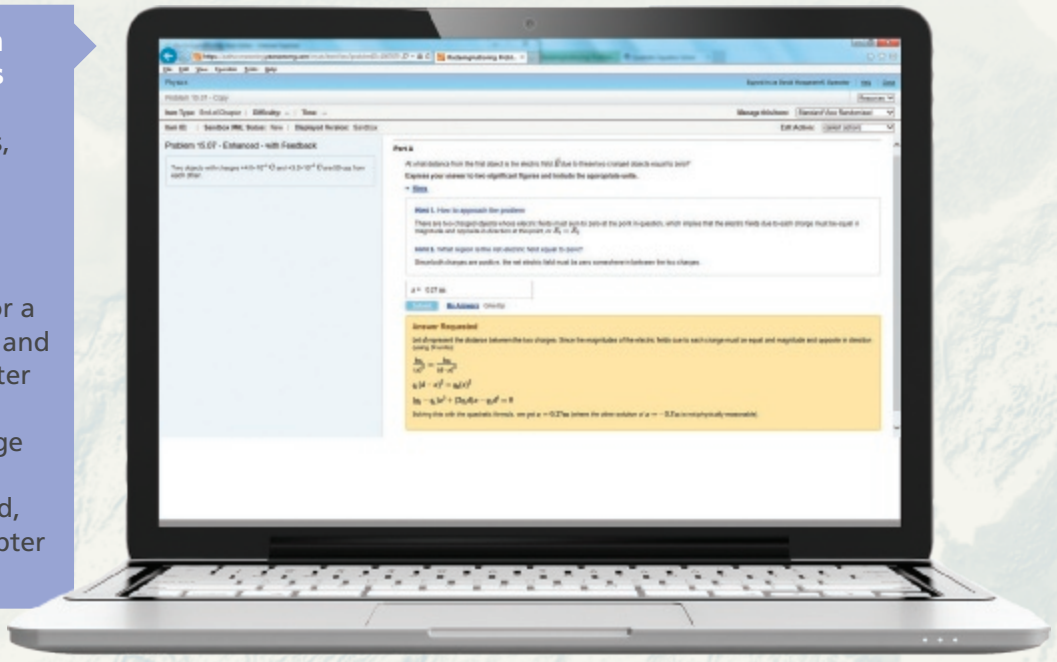
Build a basic understanding of physics principles and math skills

NEW! The Physics Primer relies on videos, hints, and feedback to refresh students' math skills in the context of physics and prepare them for success in the course. These tutorials can be assigned before the course begins as well as throughout the course as just-in-time remediation. The primer ensures students practice and maintain their math skills, while tying together mathematical operations and physics analysis.

Interactive Animated Videos provide an engaging overview of key topics with embedded assessment to help students check their understanding and to help professors identify areas of confusion. Note that these videos are not tied to the textbook and therefore do not use the language, symbols, and conceptual approaches of the book and ALG. The authors therefore recommend assigning these videos after class to expose students to different terminology and notation that they may come across from other sources.

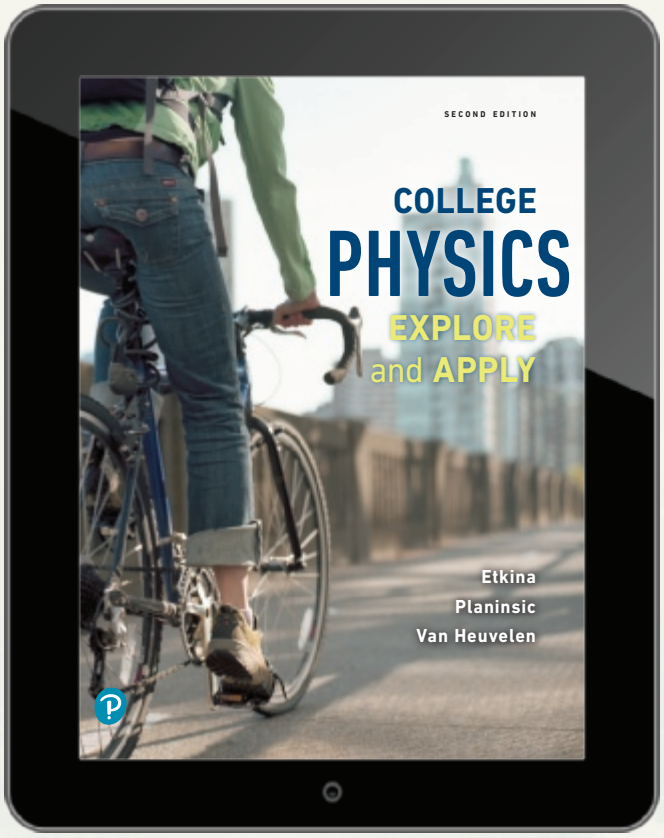


Dynamic Study Modules (DSMs) help students study effectively on their own by continuously assessing their activity and performance in real time and adapting to their level of understanding. The content focuses on definitions, units, and the key relationships for topics across all of mechanics and electricity and magnetism.



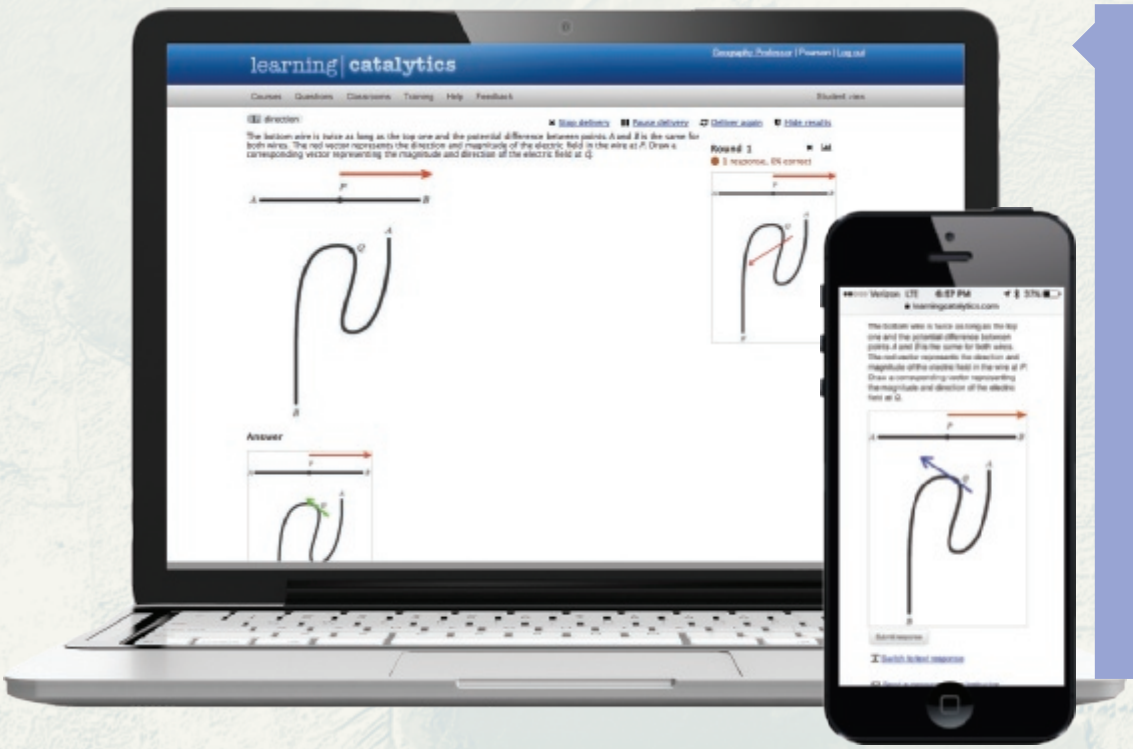
www.MasteringPhysics.com

Show connections between physics and the real world as students learn to apply physics concepts via enhanced media



NEW! Direct Measurement Videos are short videos that show real situations of physical phenomena. Grids, rulers, and frame counters appear as overlays, helping students to make precise measurements of quantities such as position and time. Students then apply these quantities along with physics concepts to solve problems and answer questions about the motion of the objects in the video.

NEW! End-of-chapter problem types and 15% new questions and problems include multiple choice with multiple correct answers, find-a-pattern in data presented in a video or a table, ranking tasks, evaluate statements/claims/explanations/measuring procedures, evaluate solutions, design a device or a procedure that meets given criteria, and linearization problems. End-of-chapter problems have undergone careful analysis using Mastering Physics usage data to provide fine-tuned difficulty ratings and to produce a more varied, useful, and robust set of end-of-chapter problems.



Give students fingertip access to interactive tools

NEW! Pearson eText, optimized for mobile, seamlessly integrates videos such as the Observational Experiment Tables and other rich media with the text and gives students access to their textbook anytime, anywhere. Pearson eText is available with Mastering Physics when packaged with new books or as an upgrade students can purchase online.

Learning Catalytics™ helps generate class discussion, customize lectures, and promote peer-to-peer learning with real-time analytics. Learning Catalytics acts as a student response tool that uses students' smartphones, tablets, or laptops to engage them in more interactive tasks and thinking.

- **NEW!** Upload a full PowerPoint® deck for easy creation of slide questions.
- **NEW!** Team names are no longer case sensitive.
- Help your students develop critical thinking skills.
- Monitor responses to find out where your students are struggling.
- Rely on real-time data to adjust your teaching strategy.
- Automatically group students for discussion, teamwork, and peer-to-peer learning.

About the Authors

EUGENIA ETKINA is a Distinguished Professor at Rutgers, the State University of New Jersey. She holds a PhD in physics education from Moscow State Pedagogical University and has more than 35 years of experience teaching physics. She is a recipient of the 2014 Millikan Medal, awarded to educators who have made significant contributions to teaching physics, and is a fellow of the AAPT. Professor Etkina designed and now coordinates one of the largest programs in physics teacher preparation in the United States, conducts professional development for high school and university physics instructors, and participates in reforms to the undergraduate physics courses. In 1993 she developed a system in which students learn physics using processes that mirror scientific practice. That system, called *Investigative Science Learning Environment* (ISLE), serves as the basis for this textbook. Since 2000, Professor Etkina has conducted over 100 workshops for physics instructors, and she co-authored the first edition of *College Physics* and the *Active Learning Guide*. Professor Etkina is a dedicated teacher and an active researcher who has published over 60 peer-refereed articles.

GORAZD PLANINSIC is a Professor of Physics at the University of Ljubljana, Slovenia. He has a PhD in physics from the University of Ljubljana. Since 2000 he has led the Physics Education program, which prepares almost all high school physics teachers in the country of Slovenia. He started his career in MRI physics and later switched to physics education research. During the last 10 years, his work has mostly focused on the research of new experiments and how to use them more productively in teaching and learning physics. He is co-founder of the Slovenian hands-on science center House of Experiments. Professor Planinsic is co-author of more than 80 peer-refereed research articles and more than 20 popular science articles, and is the author of a university textbook for future physics teachers. In 2013 he received the Science Communicator of the Year award from the Slovenian Science Foundation.

ALAN VAN HEUVELEN holds a PhD in physics from the University of Colorado. He has been a pioneer in physics education research for several decades. He taught physics for 28 years at New Mexico State University, where he developed active learning materials including the *Active Learning Problem Sheets* (the *ALPS Kits*) and the *ActivPhysics* multimedia product. Materials such as these have improved student achievement on standardized qualitative and problem-solving tests. In 1993 he joined Ohio State University to help develop a physics education research group. He moved to Rutgers University in 2000 and retired in 2008. For his contributions to national physics education reform, he won the 1999 AAPT Millikan Medal and was selected a fellow of the American Physical Society. Over the span of his career he has led over 100 workshops on physics education reform. He worked with Professor Etkina in the development of the *Investigative Science Learning Environment* (ISLE) and co-authored the first edition of *College Physics* and the *Active Learning Guide*.

Preface

To the student

College Physics: Explore and Apply is more than just a book. It's a learning *companion*. As a companion, the book won't just tell you about physics; it will act as a guide to help you build physics ideas using methods similar to those that practicing scientists use to construct knowledge. The ideas that you build will be *yours*, not just a copy of someone else's ideas. As a result, the ideas of physics will be much easier for you to use when you need them: to succeed in your physics course, to obtain a good score on exams such as the MCAT, and to apply to everyday life.

Although few, if any, textbooks can honestly claim to be a pleasure to read, *College Physics: Explore and Apply* is designed to make the process interesting and engaging. The physics you learn in this book will help you understand many real-world phenomena, from why giant cruise ships are able to float to how telescopes work. The cover of the book communicates its spirit: you learn physics by exploring the natural world and applying it in your everyday life.

A great deal of research has been done over the past few decades on how students learn. We, as teachers and researchers, have been active participants in investigating the challenges students face in learning physics. We've developed unique strategies that have proven effective in helping students think like physicists. These strategies are grounded in *active learning with your peers*—deliberate, purposeful action on your part to learn something new. For learning to happen, one needs to talk to others, share ideas, listen, explain, and argue. It is in these deliberations that new knowledge is born. Learning is not passively memorizing so that you can repeat it later. When you learn actively, you engage with the material and—most importantly—share your ideas with others. You relate it to what you already know and benefit from the knowledge of your peers. You think about the material in as many different ways as you can. You ask yourself questions such as "Why does this make sense?" and "Under what circumstances does this not apply?" Skills developed during this process will be the most valuable in your future, no matter what profession you choose.

This book (your learning companion) includes many tools to support the active learning process: each problem-solving tool, worked example, observational experiment table, testing experiment table, review question, and end-of-chapter question and problem is designed to help you build your understanding of physics. To get the most out of these tools and the course, stay actively engaged in the process of developing ideas and applying them; form a learning group with your peers and try to work on the material together. When things get challenging, don't give up.

At this point you should turn to Chapter 1, Introducing Physics, and begin reading. That's where you'll learn the details of the approach that the book uses, what physics is, and how to be successful in the physics course you are taking.

To the instructor

Welcome to the second edition of *College Physics: Explore and Apply* and its supporting materials (Mastering™ Physics, the *Active Learning Guide* (ALG), and the *Instructor's Guide*), a coherent learning system that helps our students learn physics as an ongoing process rather than a static set of established concepts and mathematical relations. It is based on a framework known as ISLE (the *Investigative Science Learning Environment*). This framework originated in the work of Eugenia Etkina in the early 1990s. She designed a logical progression of student learning of physics that mirrors the processes in which physicists engage while constructing and applying knowledge. This progression was enriched in the early 2000s when Alan Van Heuvelen added his multiple representation approach. While logical flow represents a path for thinking, multiple representations are thinking tools. Since 2001, when ISLE curriculum development began, tens of thousands of students have been exposed to it as hundreds of instructors used the materials produced by the authors and their collaborators. Research on students learning physics through ISLE has shown that these students not only master the content of physics, but also become expert problem solvers, can design and evaluate their own experiments, communicate, and most importantly see physics as a process based on evidence as opposed to a set of rules that come from the book.

Experiments, experiments… The main feature of this system is that students practice developing physics concepts by following steps similar to those physicists use when developing and applying knowledge. The first introduction to a concept or a relation happens when students observe simple experiments (called **observational experiments**). Students learn to analyze these experiments, find patterns (either qualitative or quantitative) in the data, and develop multiple explanations for the patterns or quantitative relations. They then learn how to test the explanations and relations in new **testing experiments**. Sometimes the outcomes of the experiments might cause us to reject the explanations; often, they help us keep them. Students see how scientific ideas develop from evidence and are tested by evidence, and how evidence sometimes causes us to reject the proposed explanations. Finally, students learn how tested explanations and relations are

applied for practical purposes and in problem solving. This is the process behind the subtitle of the book.

Explore and apply To help students explore and apply physics, we introduce them to tools: physics-specific representations, such as motion and force diagrams, momentum and energy bar charts, ray diagrams, and so forth. These representations serve as bridges between words and abstract mathematics. Research shows that students who use representations other than mathematics to solve problems are much more successful than those who just look for equations. We use a representations-based problem-solving strategy that helps students approach problem solving without fear and eventually develop not only problem-solving skills, but also confidence. The textbook and ALG introduce a whole library of novel problems and activities that help students develop competencies necessary for success in the 21st century: argumentation, evaluation, estimation, and communication. We use photo and video analysis, real-time data, and real-life situations to pose problems.

A flexible learning system There are multiple ways to use our learning system. Students can work collaboratively on ALG activities in class (lectures, labs, and problem-solving sessions) and then read the textbook and solve end-of-chapter problems at home, or they can first read the text and do the activities using Mastering Physics at home, then come to class and discuss their ideas. However they study, students will see physics as a living thing, a process in which they can participate as equal partners.

The key pedagogical principles of this book are described in detail in the first chapter of the *Instructor's Guide* that accompanies *College Physics*—please read that chapter. It elaborates on the implementation of the methodology that we use in this book and provides guidance on how to integrate the approach into your course.

While our philosophy informs *College Physics*, you need not fully subscribe to it to use this textbook. We've organized the book to fit the structure of most algebra-based physics courses: we begin with kinematics and Newton's laws, then move on to conserved quantities, statics, vibrations and waves, gases, fluids, thermodynamics, electricity and magnetism, optics, and finally modern physics. The structure of each chapter will work with any method of instruction. You can assign all of the innovative experimental tables and end-of-chapter problems, or only a few. The text provides thorough treatment of fundamental principles, supplementing this coverage with experimental evidence, new representations, an effective approach to problem solving, and interesting and motivating examples.

New to this edition

There were three main reasons behind the revisions in this second edition. (1) Users provided lots of feedback and we wanted to respond to it. (2) We (the authors) grew and changed, and learned more about how to help students learn, and our team changed—we have a new co-author, who is an expert in educational physics experiments and in the development of physics problems. (3) Finally, we wanted to respond to changes in the world (new physics discoveries, new technology, new skills required in the workplace) and to changes in education (the Next Generation Science Standards, reforms in the AP and MCAT exams). Our first edition was already well aligned with educational reforms, but the second edition strengthens this alignment even further.

We have therefore made the following global changes to the textbook, in addition to myriad smaller changes to individual chapters and elements:

- **An enhanced experiential approach**, with more experiment videos and photos (all created by the authors) and an updated and more focused and effective set of experiment tables, strengthens and improves the core foundation of the first edition. Approximately 150 photos and 40 videos have been added to the textbook, and even more to the ALG.
- **An expanded introductory chapter** (now Chapter 1) gives students a more detailed explanation of "How to use this book" to ensure they get the most out of the chapter features, use them actively, and learn how to think critically.
- **Integration of vector arithmetic in early chapters** allows students to develop vector-related skills in the context of learning physics, rather than its placement in an appendix in the first edition.
- **Earlier placement of waves and oscillations** allows instructors to teach these topics with mechanics if preferred. Coverage with optics is also still possible.
- **Significant new coverage of capacitors, AC circuits, and LEDs** (LEDs now permeate the whole book) expand the real-world and up-to-date applications of electricity.
- **Other new, revised, or expanded topics** include friction, 2-D collisions, energy, bar charts for rotational momentum and nuclear energy, ideal gas processes, thermodynamic engines, semiconductors, velocity selectors, and spacetime diagrams in special relativity.
- **Applications are integrated throughout each chapter,** rather than being grouped in the "Putting it all together" sections of the first edition, in order to optimize student engagement.
- **Problem-solving guidance is strengthened** by the careful revision of many Problem-Solving Strategy boxes and the review of each chapter's set of worked examples. The first edition Reasoning Skill boxes are renamed Physics Tool Boxes to better reflect their role; many have been significantly revised.
- **Streamlined text, layout, and figures** throughout the book enhance the focus on central themes and topics, eliminating extraneous detail. The second edition has over 150 fewer pages than the first edition, and the art program is updated with over 450 pieces of new or significantly revised art.
- **21st-century skills incorporated into many new worked examples and end-of-chapter problems** include data analysis, evaluation, and argumentation. Roughly 15% of all end-of-chapter questions and problems are new.
- **Careful analysis of Mastering Physics usage data** provides fine-tuned difficulty ratings and a more varied, useful, and robust set of end-of-chapter problems.
- **A fresh and modern design** provides a more transparent hierarchy of features and navigation structure, as well as an engaging chapter-opening page and streamlined chapter summary.

- **A significantly revised *Active Learning Guide*** is better integrated with the textbook, following the section sequence, and emphasizes collaboration, scientific reasoning, and argumentation.

All of the above sounds like a lot of work—and it was! But it was also lots of fun: we took photos of juice bottles sinking in the snow, we chased flying airplanes and running water striders, we drove cars with coffee cups on dashboards. Most exciting was our trip to a garbage plant to study and photograph the operation of an eddy current waste separator. Working on this new edition has enriched our lives, and we hope that using our textbook will enrich the lives of your students!

Instructor supplements

TIP All of the following materials are available for download on the Mastering Physics Instructor Resources page.

The **Instructor's Guide** (ISBN 0-134-89031-0), written by Eugenia Etkina, Gorazd Planinsic, David Brookes, and Alan Van Heuvelen, walks you through the innovative approaches they take to teaching physics. Each chapter of the *Instructor's Guide* contains a roadmap for assigning chapter content, *Active Learning Guide* assignments, homework, and videos of the experiments. In addition, the authors call out common pitfalls to mastering physics concepts and describe techniques that will help your students identify and overcome their misconceptions. Tips include how to manage the complex vocabulary of physics, when to use classroom response tools, and how to organize lab, lecture, and small-group learning time. Drawing from their extensive experience as teachers and researchers, the authors give you the support you need to make *College Physics* work for you.

The **Active Learning Guide** workbook (ISBN 0-134-60549-7) by Eugenia Etkina, David Brookes, Gorazd Planinsic, and Alan Van Heuvelen consists of carefully crafted cycles of in-class activities that provide an opportunity for students to conduct observational experiments, find patterns, develop explanations, and conduct the testing experiments for those explanations described in the textbook before they read it. These learning cycles are interspersed with "pivotal" activities that serve different purposes: (a) to introduce and familiarize students with new representational techniques, (b) to give students practice with representational techniques, (c) to directly address ideas that we *know* students struggle with (the goal is to encourage that struggle so that students reach a resolution either through their own discussion or by the instructor giving a "time for telling" lecture at the end of the activity), and (d) to provide scaffolding for students to work through an example or a passage in the textbook. The ALG also contains multiple experiments that can be used in labs. Whether the activities are assigned or not, students can always use this workbook to reinforce the concepts they have read about in the text, to practice applying the concepts to real-world scenarios, or to work with sketches, diagrams, and graphs that help them visualize the physics. The ALG is downloadable to share with your class; you may also talk to your sales representative about printing a custom version for your students.

The **Instructor Resource Materials** (ISBN 0-134-87386-6) on the Mastering Physics Instructor Resources page provide invaluable and easy-to-use resources for your class, organized by textbook chapter. The contents include a comprehensive library of all figures, photos, tables, and summaries from the textbook in JPEG and PowerPoint formats. A set of editable **Lecture Outlines**, **Open-Ended Questions**, and **Classroom Response System "Clicker" Questions** in PowerPoint will engage your students in class. Also included among the Instructor Resource Materials are the **Test Bank**, **Instructor Solutions Manual**, **Active Learning Guide**, **Active Learning Guide Solutions Manual**, and **Instructor Guide**.

Mastering™ Physics is the leading online homework, tutorial, and assessment platform designed to improve results by engaging students with powerful content. All Mastering resources, content, and tools are easy for both students and instructors to access in one convenient location. Instructors ensure that students arrive ready to learn by assigning educationally effective content before class and encourage critical thinking and retention with in-class resources such as Learning Catalytics™. Students can master concepts after class through traditional and adaptive homework assignments that provide hints and answer-specific feedback. The Mastering gradebook records scores for all automatically graded assignments in one place, while diagnostic tools give instructors access to rich data to assess student understanding and misconceptions.

New for the second edition of this book, Mastering Physics includes activities for students to do before coming to class, as an alternative to working through the *Active Learning Guide* activities prior to reading the textbook. These activities focus students' attention on observational experiments, helping them learn to identify patterns in the data, and on testing experiments, helping them learn how to make a prediction of an outcome of an experiment using an idea being tested, not personal intuition. Both skills are very important in science, but are very difficult to develop.

The significantly revised **Instructor's Solutions Manual**, provided as PDFs and editable Word files, gives complete solutions to all end-of chapter questions and problems using the textbook's problem-solving strategy.

The **Test Bank**, which has also been significantly revised, contains more than 2000 high-quality problems, with a range of multiple-choice, true/false, short-answer, and regular homework-type questions. Test files are provided in TestGen® (an easy-to-use, fully networkable program for creating and editing quizzes and exams), as well as PDF and Word format.

Student supplements

Physics experiment videos, accessed via the eText, with a smartphone through this QR code, at https://goo.gl/s2MerO, or online in the Mastering Physics Study Area, accompany most of the Observational and Testing Experiment Tables, as well as other discussions and problems in the textbook and in the ALG. Students can observe the exact experiment described in the text.

VIDEO

The **Pearson eText,** optimized for mobile, seamlessly integrates videos and other rich media with the text and gives students access to their textbook anytime, anywhere.

- The Pearson eText mobile app offers offline access and can be downloaded for most iOS and Android phones/tablets from the Apple App Store or Google Play
- Accessible (screen-reader ready)
- Configurable reading settings, including resizable type and night reading mode
- Instructor and student note-taking, highlighting, bookmarking, and search

The **Student Solutions Manual** (ISBN 0-134-88014-5) gives complete solutions to select odd-numbered end-of-chapter questions and problems using the textbook's problem-solving strategy.

In addition to content assigned by the instructor and this text's accompanying experiment videos, **Mastering™ Physics** also provides a wealth of self-study resources:

- **Dynamic Study Modules** assess student performance and activity in real time. They use data and analytics that personalize content to target each student's particular strengths and weaknesses. DSMs can be accessed from any computer, tablet, or smart phone.
- **PhET simulations** from the University of Colorado, Boulder are provided in the Mastering Physics Study Area to allow students to explore key concepts by interacting with these research-based simulations.
- **24/7 access to online tutors*** enables students to work one-on-one, in real time, with a tutor using an interactive whiteboard. Tutors will guide them through solving their problems using a problem-solving-based teaching style to help them learn underlying concepts. In this way, students will be better prepared to handle future assignments on their own.

Acknowledgments

We wish to thank the many people who helped us create this textbook and its supporting materials. First and foremost, we want to thank our team at Pearson Higher Education, especially Jeanne Zalesky, who believed that the book deserved a second edition; Alice Houston, who provided careful, constructive, creative, enriching, and always positive feedback on every aspect of the book and the ALG; Darien Estes, who fearlessly made pivotal decisions that made the new edition much better; Susan McNally, who tirelessly shepherded the book through all stages of production; and David Hoogewerff, who oversaw the Mastering Physics component of the program. Tiffany Mok and Leslie Lee oversaw the new edition of the *Active Learning Guide* and other supplements. Special thanks to Jim Smith and Cathy Murphy who helped shape the first edition of the book. We also want to thank Adam Black for believing in the future of the project.

Although Michael Gentile is not a co-author on the second edition, this work would be impossible without him; he contributed a huge amount to the first edition and provided continuous support for us when we were working on the second edition. No words will describe how grateful we are to have Paul Bunson on our team. Paul helped us with the end-of-chapter problem revisions and Mastering Physics and ALG activities, and provided many helpful suggestions, particularly on rotational mechanics, fluids, relativity, and quantum optics. In addition, he was the first to adopt the textbook even before the first edition was officially printed and since then has remained a vivid advocate and supporter of ISLE. We are indebted to Charlie Hibbard, who checked and rechecked every fact and calculation in the text. Brett Kraabel prepared detailed solutions for every end-of-chapter problem for the *Instructor's Solutions Manual*. We also want to thank all of the reviewers, in particular Jeremy Hohertz, who put their time and energy to providing thoughtful, constructive, and supportive feedback. We thank Matt Blackman for adding excellent problems to the Test Bank, Katerina Visnjic for her support of ISLE and the idea to expand energy bar charts to nuclear physics, and Mikhail Kagan for timely feedback. Our special thanks go to Lane Seeley for his thoughtful review of the energy chapter, which led to its deep revision. We thank Diane Jammula and Jay Pravin Kumar, who not only became avid supporters and users of ISLE but also helped create instructor resources for the second edition. We thank Ales Mohoric and Sergej Faletic for their suggestions on problems.

Our infinite thanks go to Xueli Zou, the first adopter of ISLE, and to Suzanne Brahmia, who came up with the Investigative Science Learning Environment acronym "ISLE" and was and is an effective user and tireless advocate of the ISLE learning strategy. Suzanne's ideas about relating physics and mathematics are reflected in many sections of the book. We are indebted to David Brookes, another tireless ISLE developer, whose research shaped the language we use. We thank all of Eugenia's students who are now physics teachers for providing feedback and ideas and using the book with their students.

We have been very lucky to belong to the physics teaching community. Ideas of many people in the field contributed to our understanding of how people learn physics and what approaches work best. These people include Arnold Arons, Fred Reif, Jill Larkin, Lillian McDermott, David Hestenes, Joe Redish, Stamatis Vokos, Jim Minstrell, David Maloney, Fred Goldberg, David Hammer, Andy Elby, Noah Finkelstein, David Meltzer, David Rosengrant, Anna Karelina, Sahana Murthy, Maria Ruibal-Villasenhor, Aaron Warren, Tom Okuma, Curt Hieggelke, and Paul D'Alessandris. We thank all of them and many others.

Personal notes from the authors

We wish to thank Valentin Etkin (Eugenia's father), an experimental physicist whose ideas gave rise to the ISLE philosophy many years ago, Inna Vishnyatskaya (Eugenia's mother), who never lost faith in the success of our book, and Dimitry and Alexander Gershenson (Eugenia's sons), who provided encouragement to Eugenia over the years. While teaching Alan how to play violin, Alan's uncle Harold Van Heuvelen provided an instructional system very different from that of traditional physics teaching. In Harold's system, many individual abilities (skills) were developed with instant feedback and combined over time to address the process of playing a complex piece of music. We tried to integrate this system into our ISLE physics learning system.

—Eugenia Etkina, Gorazd Planinsic, and Alan Van Heuvelen

*Please note that tutoring is available in selected Mastering products, and in those products you are eligible for one tutoring session of up to 30 minutes duration with your course. Additional hours can be purchased at reasonable rates.

Real-World Applications

Chapter 1

Estimating volume of drinking water for a flight 8

Chapter 2

Observing motion with a blinking LED 16
Jumping off a boulder (acceleration during landing) 35
Tailgating and driver's reaction time 40
BIO Froghopper jumps 47
BIO Squid propulsion 47
BIO Motion of a water strider 49
BIO Head injuries in sports 49
Automatic sliding doors 50

Chapter 3

Skydiving impact 67
Weighing yourself in an elevator 69
Hairdryer forces 73
Seat belts and air bags 75
BIO Bending legs when landing on a firm surface 79
Landing in snow 81
BIO Ventricle pumping blood 82
Plane crash tests 82

Chapter 4

BIO Physics of walking 91, 110
Pulling a sled 92, 96
Reading skid marks 98
Human cannonballs 106
Physics of driving 107
BIO Forces during whiplash 114
Airplane takeoff 117
Ski jumping 117

Chapter 5

BIO Fighter pilot blackout 126
Forces driving over a hump 128
Understanding a rotor ride 130
Speedway forces 132, 145
Are astronauts weightless? 138
BIO Ultracentrifuges 142
Tire pressure monitoring system 142
Relative motion and moving wheels 142
Determining adhesive forces 145
Halley's comet's motion 146

Chapter 6

Air-bag and seat-belt forces 155, 171, 172, 173
Stopping the fall of a stunt diver 161
BIO Bone fracture forces 162, 172
Rocket propulsion 164
BIO Forces in traumatic brain injury 170, 171
BIO Force exerted by heart on blood 171
BIO Leg injuries during car collisions 172
BIO Cuttlefish propulsion 173
BIO Potassium decay in body tissue
Meteorite impact with Earth 173
Analyzing a toy helicopter 174
BIO Heartbeat detector 174
Space Shuttle launch 175

Chapter 7

Physics of pole vaulting 185, 197
Analyzing roller coasters 189, 215
Reading skid marks 194
BIO Stretching the aorta 196
Black holes 206
BIO Work done by the heart 211
Wind energy 211
BIO Compressive forces in bone breaks 211
BIO Energy to climb Everest 211
BIO Froghopper jump 212
BIO Energy analysis of stairs, biking, exercising 213, 214
BIO Salmon swimming
BIO Metabolic rate 215
BIO Kangaroo hopping 216

Chapter 8

BIO Using your biceps 234
BIO Achilles tendon force 235
Lifting from a bent position 236, 248
Balancing on the subway 238
BIO Force that muscles exert on bones 244
BIO Movements that our bodies cannot do 244
Nutcracker design 246
BIO Biceps, hamstring, deltoid forces 248
BIO Neck muscle forces in football 248
Hand grip design 248
BIO Determining the mass of a part of a human body 249
BIO Muscles work in pairs 249
BIO Improper lifting and back pain 250

Chapter 9

Orbiting a black hole 255
Biceps force in throwing 265
Figure skater spinning 267
Jumping on a merry-go round 268
Pulsars, neutron stars, and white drawfs 269, 280, 282
Bicycling 270
Gyroscopes 271
Flywheels store energy 273, 281
Tides slow Earth's rotation 274
Centrifuges, mileage gauges, speedometers 278
Yo-yos 279, 282
BIO Punting a football 281
BIO Arm forces in darts and bowling 281
BIO Leg lift 281
Superball 282
Tidal energy 283

Chapter 10

Marching out of step on a bridge 284
Building vibration in high wind 288
Bouncy chair design 294
Measuring astronaut body mass in space 296
BIO Leg swinging during walking 299, 309
Vibration of CO_2 molecules and the greenhouse effect 303
Spiderweb vibrations 305
Resonance and bridge collapse 307
Detecting oil-rich geological structures with a sensitive pendulum 309
BIO Human ears and sound 311, 313

Chapter 11

BIO Human hearing and the ear 331, 347, 351
String instruments 337, 349
BIO Voice after inhaling helium 340
Wind instruments 340, 349
BIO Measuring blood flow speed 343, 350
Using light and sound to estimate distance 346
BIO Dolphin sonar 347
BIO Bats and echolocation 348, 350
BIO Reaction time 350

Chapter 12

BIO Breathing 371, 382, 383
Shrunken bottle on a plane 371, 375
BIO Scuba diving 374, 382
BIO Forced vital capacity 381
BIO Ear pop 382
Car tire pressure 382
BIO Vascular wall tension and aortic blowout 384
BIO Portable hyperbaric chamber 385

Chapter 13

BIO Glaucoma 390
Hydraulic lift 390, 410
BIO Popping your ears 395
Diving bells 397
Building a stable ship 404
Hot-air ballooning 405
BIO Altitude sickness 405
BIO Scuba diving 406
BIO Lakes freezes from top down 409, 414
BIO Blood pressure 410
BIO Intravenous feeding 410
BO Giraffe raises head 410
BIO The eardrum 410
Designing a dam 411
BIO Protein sinks in water 412
Submarine design 413
BIO Pressure in lungs 413
Measuring ocean depth using a soda bottle 413
Bubbles in champagne 413
BIO Fish bladders 413
BIO Free diving 414

Chapter 14

BIO Snoring 418
BIO Measuring blood pressure 420
Fire hoses 423, 436, 438
Blowing the roof off a house 425, 437
BIO Dislodging a plaque in an artery 426
How do airplanes fly? 427
BIO Blood flow through arteries, capillaries 430, 436, 437, 438
Terminal speed of a sky diver, skier 432, 439
BIO Flutter in blood vessel 437
BIO Effect of smoking on arteriole radius 437
BIO Protein terminal speed in water 438
BIO Thermal energy in the body due to viscous friction 439
BIO Essential hypertension 439
BIO Intravenous feeding 439
BIO The human circulatory system 440

Chapter 15

Calories in food 446
Expanding a hot air balloon 453
BIO Warming a hypothermic person 458
BIO Energy to vaporize sweat 462
Thermos bottles 465
Cooling a car engine 466
Passive solar heating 467, 473
The greenhouse effect and climate change 468
BIO Farmer's method to prevent fruit from freezing 471
BIO Dogs cooling themselves by panting 471
BIO Body temperature changes 472
BIO Cooling a hot child 473
House insulation 473
BIO Water lost during a marathon 473
BIO Tree leaf warming from sunlight 474
BIO Maintaining body temperature while running 474, 475
BIO Metabolism warming rooms 474
BIO Frostbite 474
Cloud formation 475

Chapter 16

Entropy and photosynthesis 487
Efficiency of car engines 490, 498
Refrigerators and air conditioners 492
Warming a house with a thermodynamic pump 494
BIO Human and warm-blooded animal metabolism 497, 498
BIO Efficiency of walking 498
Efficiency of nuclear power plants 498
Fuel used to counter air resistance 499

Chapter 17

Everyday electrostatic phenomena 501, 503, 507, 533
Grounding 511
The Van de Graaff generator 524
Photocopiers 526
BIO Ventricular defibrillation 530
BIO Electrical forces across cell walls 530
BIO Bee pollination 530
BIO Calcium ion synapse transfer 533
Electrostatic exploration of underground materials 533

Chapter 18

BIO Electric field and potential due to the heart's dipole 540, 547, 569
Electron speed in an X-ray machine 548
Grounding 553
Shielding during lightning 555
BIO Sodium ions in the nervous system 557–8
BIO Body cells as capacitors 561
BIO Electrocardiography (ECG) 563–4, 569
BIO Electric field across body cell membranes 568, 569
BIO Energy used to charge nerve cells 568
BIO Electric field of a fish 569, 570
BIO Axon capacitance 569
BIO Capacitance of red blood cells 569

BIO Defibrillators 569
BIO Can sharks detect an axon $\vec{E}$ field ? 570
BIO Electrophoresis 570
BIO Energy stored in an axons electric field 570
Electrostatic air cleaning devices 571

Chapter 19

Light-emitting diodes (LEDs) 583, 591
Household wiring 589, 612
Circuit breakers and fuses 599, 602
Semiconductors 606–7
BIO Electrolytes 607
BIO Preventing electric shock 610
BIO Electric currents in the body 611
BIO Current produced by electric eels 612
Subway rail resistance 613
BIO Respirator detector 613
BIO Resistance of human nerve cells 613
Conductive textiles 613
Types of household switches 614
BIO Hands and arms as a conductor 614
BIO Current across the membrane wall of an axon 614
BIO Signals in nerve cells stimulate muscles 614
BIO Effects of electric current on the human body 615

Chapter 20

Magnetic and geographic poles of Earth 617
Cathode ray tubes 628
The auroras 632
Mass spectrometers 637, 646
BIO Intensity modulated radiation therapy (IMRT) 638
BIO Magnetic force exerted by Earth on ions in the body 645
Minesweepers 646
Magnetic field sensor on your mobile phone 646
BIO Magnetic resonance imaging (MRI) 647
BIO Power lines—do their magnetic fields pose a risk? 647

Chapter 21

BIO Transcranial magnetic stimulation (TMS) 653, 664, 681
Microphones and seismometers 654
Magnetic braking 659, 683
Eddy current waste separators 659
Electric generators 666–7
Transformers 674–6, 682s
BIO Breathing monitors 679, 681
Burglar alarm design 680
Induction cooktops 680
Metal detectors 680
BIO Magnetic field and brain cells 681
BIO Hammerhead sharks 683
BIO Magnetic resonance imaging 683
Magstripe readers 683
BIO Magnetic induction tomography (MIT) 684
BIO Measuring the motion of flying insects 684

Chapter 22

Pinhole cameras 689, 708
The red-eye effect 692
BIO Measuring concentration of blood glucose 695, 697
BIO Fiber optics endoscope 701, 702
Mirages 703
Color of the sky 703
BIO Vitreous humor 708
Rain sensors 709
Rainbows 710

Chapter 23

Improving visibility with convex mirrors 716
Digital projectors 731
Magnifying glasses 732, 739
Photography and cameras 734–5
Light field cameras 736
BIO The human eye and corrective lenses 736–8, 747–749
Telescopes and microscopes 740–743, 748
BIO Seeing underwater 745
BIO Blind spots 745
Dentists' mirrors and lamps 746, 747
BIO Fish eyes, unusual and usual 746, 750
BIO Dissecting microscopes 748
BIO Laser surgery for the eye (LASIK) 749

Chapter 24

Chromatic aberration in optical instruments 759
Colors on CDs and DVDs 762
Spectrometers 762
Soap bubble colors 764, 767, 780
Lens coatings 767
BIO Bird and butterfly colors 764, 768
Resolving power of lenses 772–4, 780
Memory capacity of a CD 779
BIO Morpho butterfly wings 781
BIO Ability of a bat to detect small objects 781
BIO Diffraction-limited resolving power of the eye 782
BIO What is $20/20$ vision? 782
Thin-film window coatings for energy conservation 783

Chapter 25

Antennas 791
Radar 793–4, 810
The Global Positioning System (GPS) 794
Microwave cooking 795
Polarized sunglasses 804, 805
Liquid crystal displays (LCDs) 806
3-D movies 807
BIO Ultraviolet A and B 810
BIO X-rays used in medicine 810
BIO Laser to treat cancer 810
BIO Spider polarized light navigation 811
BIO Human vision power sensitivity 811
BIO Honeybee navigation 812
Incandescent lightbulbs 812

Chapter 26

Muons and cosmic rays 821, 824, 829
Police radar speed detector 835
Age of the universe 837, 845
Gravitational waves and black holes 839
GPS and relativity 840
BIO Mass equivalent of metabolic energy 845
Cherenkov radiation 846
Tennis serve speed measurement 846
Quasars 846

Chapter 27

Measuring stellar temperatures 849–850
X-rays 868–872
Solar cells 872, 878
Light-emitting diodes (LEDs) 874
BIO Safe photon energy in tanning beds 877
BIO Laser surgery 877
BIO Pulsed laser replaces dental drills 877
BIO Human vision sensitivity 877

BIO Energy absorption during X-rays 877
BIO Light detection by the human eye 878
BIO Firefly light 878
BIO Owl night vision 878
BIO Photosynthesis 878
BIO Radiation from our bodies 879

Chapter 28

Spectral analysis to identify chemical composition 892–5
Absorption spectrum of the Sun 896
BIO Why are plants green? 897
Lasers 897–8
BIO Laser surgery 899
Lidar mapping 899
BIO Hydrogen bonds in DNA molecules 913–914
BIO Welding the retina 917
BIO Electron microscopes 918
BIO Electron transport chains in photosynthesis and metabolism 919

Chapter 29

Fusion energy in the Sun 936
BIO Beta decay in our bodies 942
BIO Determining the source of carbon in plants 944
BIO Estimating blood volume 946
Carbon dating and archeology 947
BIO Relative biological effectiveness (RBE) of radiation 950
Sources of ionizing radiation 951
BIO Potassium decay in the body 954, 955
BIO O_2 emitted by plants 954
BIO Radiation therapy 954
BIO Dating a Wisconsin glacier tree sample 954
BIO Radiation dose 955
BIO Dose during X-ray exam 955
BIO Estimating the number of ants in a nest 955
BIO Ion production due to ionizing radiation 955
BIO Nuclear accidents and cancer risk 955, 956
Neutron activation analysis 956

Chapter 30

BIO Positron Emission Tomography (PET) 957, 962

Contents

1 Introducing Physics 1
1.1 What is physics? 2
1.2 Modeling 5
1.3 Physical quantities 6
1.4 Making rough estimates 8
1.5 Vector and scalar quantities 8
1.6 How to use this book to learn physics 9

2 Kinematics: Motion in One Dimension 13
2.1 What is motion? 14
2.2 A conceptual description of motion 15
2.3 Operations with vectors 18
2.4 Quantities for describing motion 21
2.5 Representing motion with data tables and graphs 22
2.6 Constant velocity linear motion 24
2.7 Motion at constant acceleration 30
2.8 Displacement of an object moving at constant acceleration 34
2.9 Skills for analyzing situations involving motion 37
Summary 42 • Questions and Problems 43

3 Newtonian Mechanics 51
3.1 Describing and representing interactions 52
3.2 Adding and measuring forces 55
3.3 Conceptual relationship between force and motion 56
3.4 Inertial reference frames and Newton's first law 60
3.5 Newton's second law 61
3.6 Gravitational force law 66
3.7 Skills for applying Newton's second law for one-dimensional processes 67
3.8 Forces come in pairs: Newton's third law 70
3.9 Seat belts and air bags 75
Summary 77 • Questions and Problems 78

4 Applying Newton's Laws 84
4.1 Vectors in two dimensions and force components 85
4.2 Newton's second law in component form 87
4.3 Friction 89
4.4 Skills for analyzing processes involving forces in two dimensions 96
4.5 Projectile motion 102
4.6 Starting and stopping a car 107
Summary 109 • Questions and Problems 110

5 Circular Motion 118
5.1 Qualitative dynamics of circular motion 119
5.2 Analyzing velocity change for circular motion 121
5.3 Radial acceleration and period 123
5.4 Skills for analyzing processes involving circular motion 127
5.5 The law of universal gravitation 133
Summary 139 • Questions and Problems 140

6 Impulse and Linear Momentum 147
6.1 Mass accounting 148
6.2 Linear momentum 149
6.3 Impulse and momentum 153
6.4 The generalized impulse-momentum principle 156
6.5 Skills for analyzing problems using impulse and momentum 159
6.6 Jet propulsion 163
6.7 Collisions in two dimensions 164
Summary 168 • Questions and Problems 169

7 Work and Energy 176
7.1 Work and energy 177
7.2 Energy is a conserved quantity 181
7.3 Quantifying gravitational potential and kinetic energies 186
7.4 Quantifying elastic potential energy 190
7.5 Friction and energy conversion 192
7.6 Skills for analyzing processes using the work-energy principle 194
7.7 Collisions 199

7.8 Power 202
7.9 Improving our model of gravitational potential energy 204
Summary 208 • Questions and Problems 209

8 Extended Bodies at Rest 217
8.1 Extended and rigid bodies 218
8.2 Torque: a new physical quantity 220
8.3 Conditions of equilibrium 227
8.4 Center of mass 230
8.5 Skills for analyzing situations using equilibrium conditions 233
8.6 Stability of equilibrium 237
Summary 242 • Questions and Problems 243

9 Rotational Motion 251
9.1 Rotational kinematics 252
9.2 Physical quantities affecting rotational acceleration 257
9.3 Newton's second law for rotational motion 260
9.4 Rotational momentum 266
9.5 Rotational kinetic energy 271
9.6 Tides and Earth's day 274
Summary 276 • Questions and Problems 277

10 Vibrational Motion 284
10.1 Observations of vibrational motion 285
10.2 Kinematics of vibrational motion 288
10.3 Dynamics of simple harmonic motion 292
10.4 Energy of vibrational systems 295
10.5 The simple pendulum 297
10.6 Skills for analyzing processes involving vibrational motion 299
10.7 Including friction in vibrational motion 304
10.8 Vibrational motion with an external driving force 305
Summary 308 • Questions and Problems 309

11 Mechanical Waves 315
11.1 Observations: pulses and wave motion 316
11.2 Mathematical descriptions of a wave 318
11.3 Dynamics of wave motion: speed and the medium 321
11.4 Energy, power, and intensity of waves 324
11.5 Reflection and impedance 326
11.6 Superposition principle and skills for analyzing wave processes 327
11.7 Sound 331
11.8 Standing waves on strings 335
11.9 Standing waves in air columns 338
11.10 The Doppler effect 340
Summary 345 • Questions and Problems 346

12 Gases 352
12.1 Structure of matter 353
12.2 Pressure, density, and the mass of particles 356
12.3 Quantitative analysis of an ideal gas 361
12.4 Temperature 364
12.5 Testing the ideal gas law 368
12.6 Speed distribution of particles 373
12.7 Skills for analyzing processes using the ideal gas law 374
12.8 Thermal energy, the Sun, and diffusion 376
Summary 379 • Questions and Problems 380

13 Static Fluids 386
13.1 Density 387
13.2 Pressure inside a fluid 389
13.3 Pressure variation with depth 391
13.4 Measuring atmospheric pressure 395
13.5 Buoyant force 398
13.6 Skills for analyzing static fluid problems 401
13.7 Ships, balloons, climbing, and diving 403
Summary 407 • Questions and Problems 408

14 Fluids in Motion 415
14.1 Fluids moving across surfaces—qualitative analysis 416
14.2 Flow rate and fluid speed 418
14.3 Types of fluid flow 420
14.4 Bernoulli's equation 420
14.5 Skills for analyzing processes using Bernoulli's equation 424
14.6 Viscous fluid flow 428
14.7 Drag force 431
Summary 435 • Questions and Problems 435

15 First Law of Thermodynamics 441
15.1 Internal energy and work in gas processes 442
15.2 Two ways to change the energy of a system 445
15.3 First law of thermodynamics 448
15.4 Applying the first law of thermodynamics to gas processes 451
15.5 Specific heat 455
15.6 Phase change 458
15.7 Heating mechanisms 463
Summary 470 • Questions and Problems 471

16 Second Law of Thermodynamics 476
16.1 Irreversible processes 477
16.2 Entropy: the microscopic approach 480
16.3 Entropy: the macroscopic approach 484
16.4 Quantitative analysis of thermodynamic engines and pumps 488
Summary 495 • Questions and Problems 496

17 Electric Charge, Force, and Energy 500
17.1 Electrostatic interactions 501
17.2 Explanations for electrostatic interactions 504
17.3 Conductors and insulators (dielectrics) 507
17.4 Coulomb's force law 512
17.5 Electric potential energy 516
17.6 Skills for analyzing processes involving electric charges 521
17.7 Charge separation and photocopying 524
Summary 528 • Questions and Problems 529

18 The Electric Field 535
18.1 A model of the mechanism for electrostatic interactions 536
18.2 Skills for analyzing processes involving $\vec{E}$ fields 542
18.3 The V field: electric potential 546
18.4 Relating the $\vec{E}$ field and the V field 550
18.5 Conductors in electric fields 552
18.6 Dielectric materials in an electric field 555
18.7 Capacitors 558
18.8 Electrocardiography 563
Summary 565 • Questions and Problems 566

19 DC Circuits 572
19.1 Electric current 573
19.2 Batteries and emf 576
19.3 Making and representing simple circuits 578
19.4 Ohm's law 581
19.5 Qualitative analysis of circuits 586
19.6 Joule's law 589
19.7 Kirchhoff's rules 592
19.8 Resistor and capacitor circuits 596
19.9 Skills for solving circuit problems 600
19.10 Properties of resistors 602
Summary 608 • Questions and Problems 609

20 Magnetism 616
20.1 Magnetic interactions 617
20.2 Magnetic field 618
20.3 Magnetic force on a current-carrying wire 621
20.4 Magnetic force exerted on a single moving charged particle 628
20.5 Magnetic fields produced by electric currents 632
20.6 Skills for analyzing magnetic processes 634
20.7 Magnetic properties of materials 639
Summary 642 • Questions and Problems 643

21 Electromagnetic Induction 649
21.1 Inducing an electric current 650
21.2 Magnetic flux 654
21.3 Direction of the induced current 656
21.4 Faraday's law of electromagnetic induction 659
21.5 Skills for analyzing processes involving electromagnetic induction 662
21.6 AC circuits 668
21.7 Transformers 674
21.8 Mechanisms explaining electromagnetic induction 677
Summary 678 • Questions and Problems 679

22 Reflection and Refraction 685
22.1 Light sources, light propagation, and shadows 686
22.2 Reflection of light 689
22.3 Refraction of light 692
22.4 Total internal reflection 696
22.5 Skills for analyzing reflective and refractive processes 698
22.6 Fiber optics, prisms, mirages, and the color of the sky 701
22.7 Explanation of light phenomena: two models of light 704
Summary 706 • Questions and Problems 707

23 Mirrors and Lenses 712
23.1 Plane mirrors 713
23.2 Qualitative analysis of curved mirrors 715
23.3 The mirror equation 721
23.4 Qualitative analysis of lenses 725
23.5 Thin lens equation and quantitative analysis of lenses 730
23.6 Skills for analyzing processes involving mirrors and lenses 734
23.7 Single-lens optical systems 735
23.8 Angular magnification and magnifying glasses 739
23.9 Telescopes and microscopes 740
Summary 744 • Questions and Problems 745

24 Wave Optics 751
24.1 Young's double-slit experiment 752
24.2 Refractive index, light speed, and wave coherence 757
24.3 Gratings: an application of interference 760
24.4 Thin-film interference 764
24.5 Diffraction of light 768
24.6 Resolving power 772
24.7 Skills for applying the wave model of light 774
Summary 777 • Questions and Problems 778

25 Electromagnetic Waves 784
25.1 Polarization of waves 785
25.2 Discovery of electromagnetic waves 788
25.3 Applications of electromagnetic waves 793
25.4 Frequency, wavelength, and the electromagnetic spectrum 795
25.5 Mathematical description of EM waves and EM wave energy 797
25.6 Polarization and light reflection 802
Summary 808 • Questions and Problems 809

26 Special Relativity 813
26.1 Ether or no ether? 814
26.2 Postulates of special relativity 817
26.3 Simultaneity 818
26.4 Time dilation 819
26.5 Length contraction 822
26.6 Spacetime diagrams 824
26.7 Velocity transformations 827
26.8 Relativistic momentum 828
26.9 Relativistic energy 830
26.10 Doppler effect for EM waves 834
26.11 General relativity 838

Introducing Physics

In everyday life, a model of something (such as a model airplane or a model train) is usually a smaller, simpler, or idealized version of the original. An architect creates a model to show a building's essential elements and context. Physicists do something similar, but it might surprise you to hear that in physics, a marble is a very useful model of an airplane, a car, or the Moon. Read on and you will learn why.

- **What are physics models?**
- **How is the word "law" used differently in physics than in the legal system?**
- **How do we solve physics problems such as determining the minimum runway length needed for an airplane?**

WHETHER YOU'VE STUDIED ANY physics before or not, it's helpful to take a step back and consider what physics is about and how physicists think about things. You'll find that learning to analyze problems like a physicist will help you not only in this course, but also in others (and in life in general). This book is designed to help you do this, and this chapter will give you an overview of how to use this book to your best advantage.

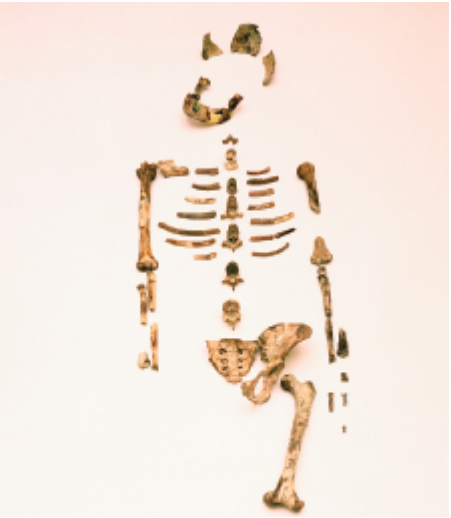

FIGURE 1.1 Archaeologists applied principles from physics to determine that this skeleton of *Australopithecus afarensis*, nicknamed "Lucy," lived about 3.2 million years ago.

1.1 What is physics?

Physics is a fundamental experimental science encompassing subjects such as motion, waves, light, electricity, magnetism, atoms, and nuclei. Knowing physics allows you to understand many aspects of the world, from why bending over to lift a heavy load can injure your back to why Earth's climate is changing. Physics explains the very small—atoms and subatomic particles—and the very large—planets, galaxies, and black holes.

In each chapter of this textbook, we will apply our knowledge of physics to other fields of science and technology such as biology, medicine, geology, astronomy, architecture, engineering, agriculture, and anthropology. For instance, you will learn about techniques used by archeologists to determine the age of bones (**Figure 1.1**), about electron microscopes and airport metal detectors, and why high blood pressure indicates problems with the circulatory system.

In this book we will concentrate not only on developing an understanding of the important basic laws of physics but also on the processes that physicists employ to discover and use these laws. The processes (among many) include:

- Collecting and analyzing experimental data.
- Making explanations and experimentally testing them.
- Creating different representations (pictures, graphs, bar charts, etc.) of physical processes.
- Finding mathematical relations—mathematical models—between different variables.
- Testing those relations in new experiments.

The search for rules

Physicists search for general rules, or **laws**, that bring understanding to the chaotic behavior of our surroundings. In physics the word *law* means a causal mathematical relation between variables inferred from the data or through some reasoning process. Causal relations show how change in one quantity affects the change in another quantity, but they do not explain why such causation occurs. The laws, once discovered, often seem obvious, yet their discovery usually requires years of experimentation and theorizing. Despite being called "laws," they are temporary in the sense that new information often leads to their modification, revision, and, in some cases, abandonment.

For example, in 200 B.C. Apollonius of Perga watched the Sun and the stars moving in arcs across the sky and adopted the concept that Earth occupied the center of a revolving universe. Three hundred years later, Ptolemy developed a detailed model to explain the complicated motion of the planets in that Earth-centered universe. Ptolemy's model, which predicted with surprising accuracy the changing positions of the planets, was accepted for the next 1400 years. However, as the quality of observations improved, discrepancies between the predictions of Ptolemy's model and the real positions of the planets became bigger and bigger. A new model was needed. Copernicus, who studied astronomy around the time that Columbus sailed to America, developed a model of motion for the heavenly bodies in which the Sun resided at the center of the universe while Earth and the other planets moved in orbits around it. More than 100 years later the model was revised by Johannes Kepler and later supported by careful experiments by Galileo Galilei. Finally, 50 years after Galileo's death, Isaac Newton formulated three simple laws of motion and the universal law of gravitation, which together provided a successful explanation for the orbital motion of Earth and the other planets. These laws also allowed us to predict the positions of new planets, which at the time were not yet known. Newton's work turned the heliocentric model into the theory of gravitation. For nearly 300 years Newtonian theory went unaltered until Albert Einstein made several profound improvements to our understanding of motion and gravitation at the beginning of the 20th century.

Newton's inspiration provided not only the basic resolution of the 1800-year-old problem of the motion of the planets but also a general framework for analyzing the mechanical properties of nature (**Figure 1.2**). Newton's simple laws give us the understanding needed to guide rockets to the Moon, to build skyscrapers, and to lift heavy objects safely without injury.

It is difficult to appreciate the great struggles our predecessors endured as they developed an understanding that now seems routine. Today, similar struggles occur in most branches of science, though the questions being investigated have changed. How does the brain work? What causes Earth's magnetism? What is the nature of the pulsating sources of X-ray radiation in our galaxy? Is the recently discovered accelerated expansion of the universe really caused by a mysterious "dark energy," or is our interpretation of the observations of distant supernovae that revealed the acceleration incomplete?

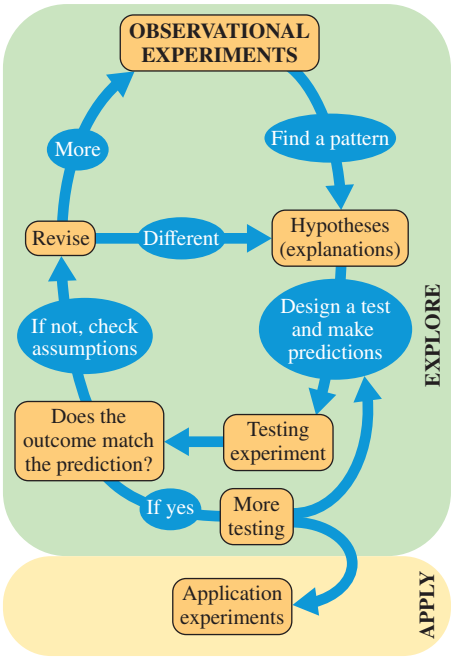
FIGURE 1.2 Thanks to Newton, we can explain the motion of the Moon. We can also build skyscrapers.

The processes for devising and using new models

Physics is an experimental science. To answer questions, physicists do not just think and dream in their offices but constantly engage in experimental investigations. Physicists use special measuring devices to observe phenomena (natural and planned), describe their observations (carefully record them using words, numbers, graphs, etc.), find repeating features called patterns (for example, the distance traveled by a falling object is directly proportional to the square of the time in flight), and then try to explain these patterns. By doing this, physicists describe and answer the questions of "why" or "how" the phenomena happened and then deduce quantitative rules called mathematical models that explain the phenomena.

However, a deduced explanation or a mathematical model is not automatically accepted as true. Every model needs to undergo careful testing. When physicists test a model, they use the model to predict the outcomes of new experiments. As long as there is no experiment whose outcome is inconsistent with predictions made using the model, it is not disproved. However, a new experiment could be devised tomorrow whose outcome is not consistent with the prediction made using the model. The point is that there is no way to "prove" a model once and for all. At best, the model just hasn't been disproven yet.

A simple example will help you understand some processes that physicists follow when they study the world. Imagine that you walk into the house of your acquaintance Bob and see 10 tennis rackets of different quality and sizes. This is an **observational experiment**. During an observational experiment a scientist collects data that seem important. Sometimes it is an accidental or unplanned experiment. The scientist has no prior expectation of the outcome. In this case the number of tennis rackets and their quality and sizes represent the data. Having so many tennis rackets seems unusual to you, so you try to explain the data you collected (or, in other words, to explain why Bob has so many rackets) by devising several hypotheses. A **hypothesis** is an explanation that usually is based on some mechanism that is behind what is going on, or it can be a mathematical model describing the phenomenon. One hypothesis is that Bob has lots of children and they all play tennis. A second hypothesis is that Bob makes his living by fixing tennis rackets. A third hypothesis is that he is a thief who steals tennis rackets.



How do you decide which hypothesis is correct? You may reason: if Bob has many children who play tennis, and I walk around the house checking the sizes of clothes that I find, then I will find clothes of different sizes. Checking the clothing sizes is a new experiment, called a **testing experiment**. A testing experiment is different from an observational experiment. In a testing experiment, a specific hypothesis is being "put on trial." This hypothesis is used to construct a clear expectation of the outcome of the experiment. This clear expectation (based on the hypothesis being tested) is called a **prediction**. So you conduct the testing experiment by walking around the house checking the closets. You do find clothes of different sizes. This is the **outcome** of your testing experiment. Does it mean for absolute certain that Bob has the rackets

TIP Notice the difference between a hypothesis and a prediction. A *hypothesis* is an idea that explains why or how something that you observe happens. A *prediction* is a statement of what should happen in a particular experiment if the hypothesis being tested were true. The prediction is based on the hypothesis and cannot be made without a specific experiment in mind.

because all of his children play tennis? No; he could still be a racket repairman or a thief. Therefore, if the outcome of the testing experiment matches the prediction based on your hypothesis, you cannot say that you proved the hypothesis. All you can say is that you failed to disprove it. However, if you walk around the house and do not find any children's clothes, you can say with more confidence that the number of rackets in the house is not due to Bob having lots of children who play tennis. Still, this conclusion would only be valid if you made an **assumption**: Bob's children live in the house and wear clothes of different sizes. Generally, in order to reject a hypothesis you need to check the additional assumptions you made and determine if they are reasonable.

Imagine you have rejected the first hypothesis (you didn't find any children's clothes). Next you wish to test the hypothesis that Bob is a thief. This is your reasoning: *If* Bob is a thief (the hypothesis), *and* I walk around the house checking every drawer (the testing experiment), *then* I will not find any receipts for the tennis rackets (the prediction). You perform the experiment and you find no receipts. Does it mean that Bob is a thief? He might just be a disorganized father of many children or a busy repairman. However, if you find all of the receipts, you can say with more confidence that he is not a thief (but he could still be a repairman). Thus it is possible to disprove (rule out) a hypothesis, but it is not possible to prove it once and for all. The process that you went through to create and test your hypotheses is depicted in **Figure 1.3**. At the end of your investigation you might be left with a hypothesis that you failed to disprove. As a physicist you would now have some confidence in this hypothesis and start using it for practical applications.

FIGURE 1.3 Science is a cyclical process for creating and testing knowledge.

Using this textbook you will learn physics by following a process similar to that described above. The section "How to use this book to learn physics" at the end of this chapter will explain how to master this process.

Physicists use words and the language of mathematics to express ideas about the world. But they also represent these ideas and the world itself in other ways—sketches, diagrams, and even cut-out paper models (James Watson made a paper model of DNA when trying to determine its structure). In physics, however, the ultimate goal is to understand the mechanisms behind physical phenomena and to devise mathematical models that allow for quantitative predictions of new phenomena. Thus, a big part of physics is identifying measurable properties of the phenomena (such as mass, speed, and force), collecting quantitative data, finding the patterns in that data, and creating mathematical models representing relations between the quantities.

How will learning physics change your interactions with the world?

Even if you do not plan on becoming a professional physicist, learning physics can change the way you think about the world. For example, why do you feel cold when you wear wet clothes? Why is it safe to sit in a car during a lightning storm? Knowing physics will also help you understand what underlies many important technologies. How can a GPS know your present position and guide you to a distant location? How do power plants generate electric energy?

Studying physics is also a way to acquire the processes of knowledge construction, which will help you make decisions based on evidence rather than on personal opinions. When you hear an advertisement for a shampoo claim it will make your hair 97.5% stronger, you will ask: How do they know this? Did this number come from an experiment? If it did, was it tested? What assumptions did they make? Did they control for food consumed, exercise, air quality, etc.? Understanding physics will help you differentiate between actual evidence and unsubstantiated claims. For instance, before you accept a claim, you might ask about the data supporting the claim, what experiments were used to test the idea, and what assumptions were made. Thinking critically about the messages you hear will change the way you make decisions as a consumer and a citizen.

1.2 Modeling

You already met the word "model" in this chapter. In this section we will learn more about this term. Physicists study how the complex world works. To start the study of some aspect of that world, they often begin with a simplified version. Consider how you move your body when you walk. Your back foot on the pavement lifts and swings forward, only to stop for a short time when it again lands on the pavement, now ahead of you. Your arms swing back and forth. The trunk of your body moves forward steadily. Your head also moves forward but bobs up and down slightly. It would be very difficult to start our study of motion by analyzing all these complicated parts and movements. Thus, physicists create in their minds simplified representations, called **models**, of physical phenomena and then think of the phenomena in terms of those models. Physicists begin with very simple models and then add complexity as needed to investigate more detailed aspects of the phenomena.

A simplified object

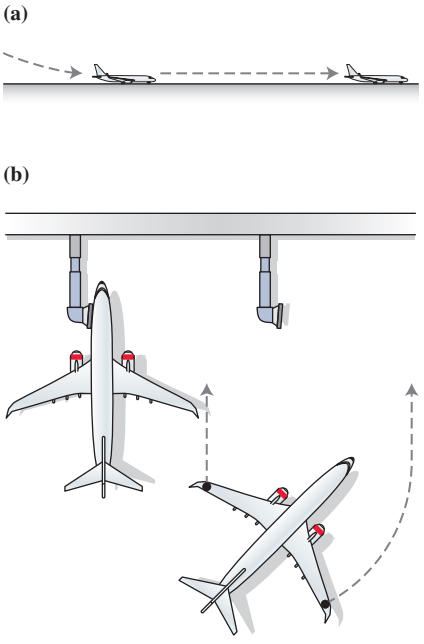
To simplify real objects, physicists often neglect both the dimensions of objects (their sizes) and their structures (the different parts) and instead regard them as single **point-like objects** (Figure 1.4).

Is modeling a real object as a point-like object a good idea? Imagine a 100-m race. The winner is the first person to get a body part across the finish line. The judge needs to observe the movement of all body parts (or a photo of the parts) across a very small distance near the finish line to determine who had the fastest time. Here, that very small distance near the finish line is small compared to the size of the human body. This is a situation where modeling the runners as point-like objects is not reasonable. However, if you are interested in how long it takes an average person to run 100 m, then the movement of different body parts is not as important, since 100 m is much larger than the size of a runner. In this case, the runners can be modeled as point-like objects. Even though we are talking about the same situation (a 100-m race), the aspect of the situation that interests us determines how we choose to model the runners.

Consider an airplane landing on a runway (Figure 1.5a). We want to determine how long it takes for it to stop. Since all of its parts move together, the part we study does not matter. In that case it is reasonable to model the airplane as a point-like object. However, if we want to build a series of gates for planes to unload passengers (Figure 1.5b), then we need to consider the motion of the different parts of the airplane. For example, there must be enough room for an airplane to turn while maneuvering into and out of the gate. In this case the airplane cannot be modeled as a point-like object.

Point-like object A point-like object is a simplified representation of a real object. As a rule of thumb, you can model a real object as a point-like object when one of the following two conditions is met: (a) when all of its parts move in the same way, or (b) when the object is much smaller than the other relevant lengths in the situation. The same object can be modeled as a point-like object in some situations but not in others.

Modeling



The process that we followed to decide when a real object could be considered a point-like object is an example of what is called **modeling**. The modeling of objects is the first step that physicists use when they study natural phenomena. In addition to simplifying the objects that they study, scientists simplify the interactions between objects and also the processes that are occurring in the real world. Then they add complexity as their understanding grows. Galileo Galilei is believed to be the first scientist to consciously model a phenomenon. In his studies of falling objects in the early 17th century, he chose to simplify the real phenomenon by ignoring the interactions of the falling objects with the air.

FIGURE 1.4 Physicists often model complex structures as point-like objects.

We can ignore the chassis flexing and the driver moving and model this racecar as a point-like object in order to study its motion.

FIGURE 1.5 An airplane can be considered a point-like object (a) when landing, but not (b) when parking.

Modeling A model is a simplified representation of an object, a system (a group of objects), an interaction, or a process. A scientist creating the model decides which features to include and which to neglect.

As you see from above, there are different kinds of models. Those important for physics are mathematical models of processes. Models allow us to predict future phenomena.

1.3 Physical quantities

To describe physical phenomena quantitatively and model them mathematically, physicists construct **physical quantities**: features or characteristics of phenomena that can be determined experimentally, directly or indirectly. Determining the value of a physical quantity means comparing the characteristic to an assigned **unit** (a chosen standard).

Units of measure

Physicists describe physical quantities using the **SI system**, or *Le Système international d'unités*, whose origin goes back to the 1790s when King Louis XVI of France created a special commission to invent a new metric system of units. For example, in the SI system length is measured in meters. One meter is approximately the distance from your nose to the tip of the fingers of your outstretched arm. A long step is about one meter. Other units of length are related to the meter by powers of 10 using **prefixes** (milli, kilo, nano, …). These prefixes relate smaller or bigger versions of the same unit to the basic unit. For example, 1 millimeter is 0.001 meter; 1 kilometer is 1000 meters. The prefixes are used when a measured quantity is much smaller or much larger than the basic unit. If the distance is much larger than 1 m, you might want to use the kilometer $(10^3\ \text{m})$ instead. The most common prefixes and the powers of 10 to which they correspond are given in **Table 1.1**. In addition to the unit of length, the SI system has six other basic units, summarized in **Table 1.2**.

TABLE 1.1 Power of 10 prefixes

Prefix	Abbreviation	Value
Tera	T	10^{12}
Giga	G	10^{9}
Mega	M	10^{6}
Kilo	k	10^{3}
Hecto	h	10^{2}
Deka	da	10^{1}
Deci	d	10^{-1}
Centi	c	10^{-2}
Milli	m	10^{-3}
Micro	μ	10^{-6}
Nano	n	10^{-9}
Pico	p	10^{-12}
Femto	f	10^{-15}

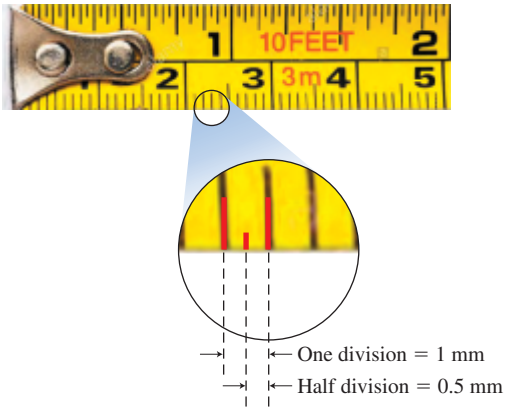
TABLE 1.2 Basic SI physical quantities and their units

Physical quantity	Unit name and symbol	Physical description (approximate value)
Time	Second, s	One second is the time it takes for the heart to beat once.
Length	Meter, m	One meter is the length of one stride.
Mass	Kilogram, kg	One kilogram is the mass of 1 liter of water.
Electric current	Ampere, A	One ampere is the electric current through super bright white LEDs, such as those used in some street lamps.
Temperature	Kelvin, K	One kelvin degree is the same as 1 degree on the Celsius scale or about 2 degrees on the Fahrenheit scale. Half a kelvin (about 1 degree Fahrenheit) is the smallest temperature difference that the average person can detect by touching (with your hands).
Amount of matter	Mole, mol	One mole of anything contains 6×10^{23} of the units; one mole of oranges contains 6×10^{23} oranges.
Intensity of light	Candela, cd	One candela is the intensity of light produced by a relatively large candle at a distance of 1 m.

Table 1.2 provides a "feel" for some of the units but does not say exactly how each unit is defined. More careful definitions are important in order that measurements made by scientists in different parts of the world are consistent. However, to understand the precise definitions of these units, one needs to know more physics. We will learn how each unit is precisely defined when we investigate the concepts on which the definition is based.

Measuring instruments

Physicists use a measuring instrument to compare the quantity of interest with a standardized unit. Each measuring instrument is calibrated so that it reads in multiples of that unit. Some examples of measuring instruments are a thermometer to measure temperature (calibrated in degrees Celsius or degrees Fahrenheit), a watch to measure time intervals (calibrated in seconds), and a meter stick to measure the height of an object (calibrated in millimeters). We can now summarize these ideas about physical quantities and their units.



Physical quantity A physical quantity is a feature or characteristic of a physical phenomenon that can be measured in some unit. A measuring instrument is used to make a quantitative comparison of this characteristic with a unit of measure. Examples of physical quantities are your height, your body temperature, the speed of your car, and the temperature of air or water.

Significant digits

When we measure a physical quantity, the instrument we use and the circumstances under which we measure it determine how precisely we know the value of that quantity. Imagine that you wear a pedometer (a device that measures the number of steps that you take) and wish to determine the number of steps on average that you take per minute. You start walking at 3 p.m. according to your analog watch and stop when it shows 3:26, and see that the pedometer shows 2254 steps. You divide 2254 by 26 using your calculator, and it says 86.692307692307692. If you accept this number, it means that you know the number of steps per minute within plus or minus 0.000000000000001 steps/min. If you accept the number 86.69, it means that you know the number of steps to within 0.01 steps/min. If you accept the number 90, it means that you know the number of steps within 10 steps/min. Which answer should you use?

To answer this question, let's first focus on the measurements. Although it seems that you walked for 26 min, you could have walked for as few as 25 min or for as many as 27 min depending on whether you started a little after 3 p.m. or finished a little after 3:26. The number 26 does not give us enough information to know the time more precisely than that. The time measurement 26 min has two **significant digits**, or two numbers that carry meaning contributing to the precision of the result. The pedometer measurement 2254 has four significant digits. Should the result of dividing the number of steps by the amount of time you walked have two or four significant digits? If we accept four, it means that the number of steps per minute is known more precisely than the time measurement in minutes. This does not make sense. The number of significant digits in the final answer should be the same as the number of significant digits of the quantity used in the calculation that has the *smallest number of significant digits*. Thus, in our example, the average number of steps per minute should be 87. We rounded the result given by the calculator to two significant digits. This example shows that when we divide (or multiply) one term by another value, the number of significant digits in the result cannot be greater than the number of the significant digits in the term that has the fewest—in our case, two digits in the time. However, as we add or subtract values, the answer cannot have more decimal places than the term with fewest decimal places. For example, $30.517\ \text{s} + 0.3\ \text{s} = 30.8\ \text{s}$.

FIGURE 1.6 The precision of an instrument is determined by one-half of its smallest division. The smallest division of this measuring tape is 1 mm, so the precision is 0.5 mm.

Another issue with significant digits arises when a quantity is reported with no decimal points. For example, how many significant digits does 6500 have—two or four? This is where scientific notation helps. **Scientific notation** means writing numbers in terms of their power of 10. For example, we can write 6500 as 6.5×10^3. This means that the 6500 actually has two significant digits: 6 and 5. If we write 6500 as 6.50×10^3, it means 6500 has three significant digits: 6, 5, and 0. The number 6.50 is more precise than the number 6.5, because it means that you are confident in the number to the hundredths place. Scientific notation provides a compact way of writing large and small numbers and also allows us to indicate unambiguously the number of significant digits a quantity has.

Because we use instruments to measure quantities, we need to connect our knowledge of significant digits to the measurements. When we measure a quantity, we talk about precision. The **precision** of the value of a physical quantity is determined by one of two cases.

1. If the quantity is measured by a single instrument, its precision depends on the instrument used to measure it. Figure 1.6 shows how the design of the measuring instrument determines its precision.
2. If the quantity is calculated from other measured quantities, then its precision depends on the least precise instrument out of all the instruments used to measure a quantity used in the calculation.

1.4 Making rough estimates

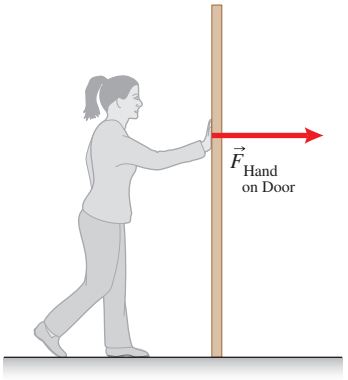
Sometimes it is useful to make a rough estimate of a physical quantity to help assess a situation or to make a decision. To do this, we use our personal knowledge or experience to get an approximate numerical value for an unknown quantity. Often the goal of the rough estimate is to determine the *order of magnitude* of the quantity—is it tens, hundreds, or thousands of the relevant units? Estimating is an extremely valuable skill not only in science but also in everyday life (Figure 1.7).

FIGURE 1.7 In everyday life, rough estimates are often sufficient.

For example, suppose we want to estimate the amount of drinking water that needs to be taken on a passenger airplane for a 4-h flight. We don't know exactly how many passengers are on the plane, but perhaps we assume that there are about 30 rows of seats with six seats per row. These data allow us to estimate the number of passengers: $30 \times 6 = 180$. After adding the crew and rounding the number, we can estimate the number of passengers to be 200. How many cups of water will each passenger drink? Some may drink six, but some only one. It seems reasonable to estimate that each person will drink about a cup of water every hour during the flight. Therefore, during a 4-h flight, 200 people will drink about 800 cups of water. How much water is in 1 cup? Again, if we don't know exactly, we can estimate it to be about 200 mL (a can of Coke holds about 350 mL). Our final estimation for the amount of water needed on the airplane is therefore 160,000 mL, or 160 L. You could argue that the airplane might be larger (with, say, 40 rows of eight seats) and that if the flight is during the daytime, people might drink more water (say six glasses per person). If you repeat the calculation using these new numbers, you will get about 380 L of water. This number is larger than our first estimate, but the order of magnitude is the same—hundreds of liters.

1.5 Vector and scalar quantities

There are two general types of physical quantities—those that contain information about magnitude as well as direction and those that contain magnitude information only. Physical quantities that do not contain information about direction are called **scalar quantities** and are written using *italic* symbols (m, T, etc.). Mass is a scalar



quantity, as is temperature (**Figure 1.8**). To manipulate scalar quantities, you use standard arithmetic and algebra rules—you add, subtract, multiply, and divide scalars as though they were ordinary numbers.

Physical quantities that contain information about magnitude and direction are called **vector quantities** and are represented by italic symbols with an arrow on top ($\vec{F}$, $\vec{v}$, etc.). The little arrow on top of the symbol always points to the right. The actual direction of the vector quantity is shown in a diagram. For example, force is a physical quantity with both magnitude and direction (direction is very important if you are trying to hammer a nail into the wall). When you push a door, your push can be represented with a force arrow on a diagram; the stronger you push, the longer that arrow must be. The direction of the push is represented by the direction of that arrow (**Figure 1.9**). The arrow's direction indicates the direction of the vector, and the arrow's relative length indicates the vector's magnitude. The methods for manipulating vector quantities (adding and subtracting them as well as multiplying a vector quantity by a scalar quantity) will be introduced as needed in the following chapters.

FIGURE 1.8 Temperature is a scalar quantity; it has magnitude, but not direction. However, it can be positive or negative.

FIGURE 1.9 The force that your hand exerts on a door is a vector quantity represented by an arrow.

1.6 How to use this book to learn physics

The goals of this textbook are to help you construct understanding of some of the most important ideas in physics, learn to use physics knowledge to analyze physical phenomena, and develop the general process skills that scientists use in the practice of science. One such skill is learning from a scientific text. Thus, by learning to work with your textbook efficiently and productively, you will not only learn physics but also develop textbook reading skills that will be helpful in any other science subject you study. To take advantage of all the tools that this textbook has to offer, we suggest that you read the text below and then, after you work through the first few chapters, come back to this section and read it again.

The most important strategy that will help you learn better is called **interrogation**. Interrogation means continually asking yourself the same question when reading the text. This question is so important that we put it in the box below:

Why is this true?

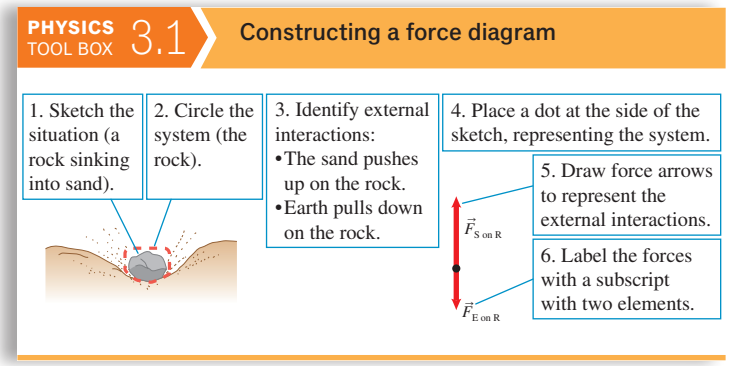
Make sure that you ask yourself this question as often as possible so that eventually it becomes a habit. Out of all the strategies that are recommended for reading comprehension, this is the one that is directly connected to better learning outcomes. For example, in Section 1.2 you read the following sentence: "The modeling of objects is the first step that physicists use when they study natural phenomena." Ask yourself, "Why is this true?" Possibly because real-life phenomena are too complicated to be investigated in detail—it is much easier to describe the motion of a runner if you consider her to be a point-like object than to take into account the details of her arms, legs, hair, etc. Thus, simplifying, (or as physicists call it, modeling) is the first step that we take. By just stopping and interrogating yourself as often as possible about what is written in the book you will be able to understand and remember this information better.

Textbook features

This textbook has several features that repeat in every chapter. Recognizing these features and using them effectively not only will help you learn physics and shorten the time that you spend doing so, but also will help you develop good reading habits.

Chapter-opening page and connection to real life

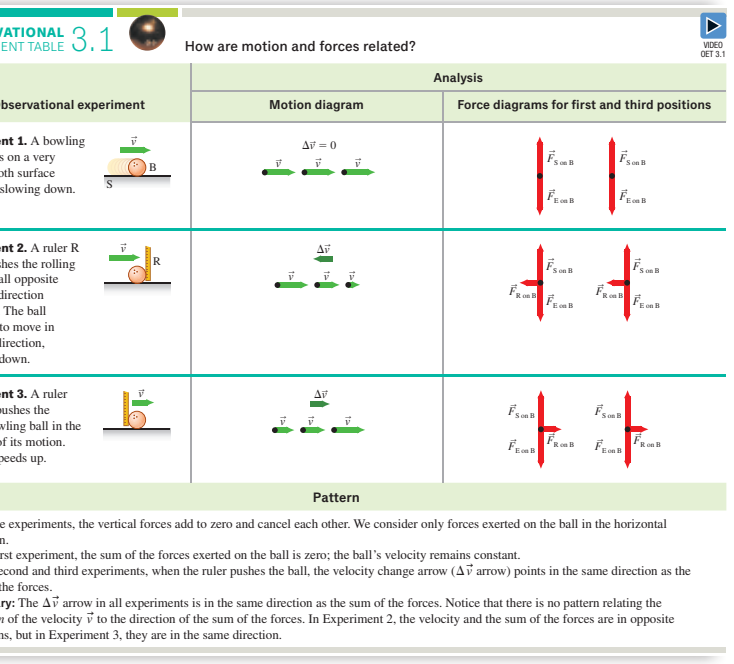
The large photo at the beginning of each chapter shows an aspect of your life or the world around you that can be explained using the physics in the chapter. The three questions in the margin below the photo also help you connect chapter material to real life or some exciting applications. The questions are all answered in the chapter, often in a quantitative way. For example, in Chapter 3, the question "How do seat belts and air bags save lives?" is answered in the last section, "Seat belts and air bags." When you start working with a new chapter, read the questions and the short explanation below the photo to get motivated about the material in the chapter. People learn and remember new knowledge much better if they are motivated to learn!



BE SURE YOU KNOW HOW TO:
- Draw a motion diagram for a moving object (Section 2.2).
- Determine the direction of acceleration using a motion diagram (Section 2.7).
- Add vectors graphically and determine their components (Sections 2.3, 2.4, and 2.6).

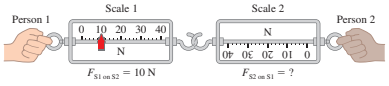
Be sure you know how to

At the bottom of each chapter-opening page is a bulleted list referring to sections from earlier chapters. This list highlights concepts and skills that are necessary to be successful in learning the upcoming new material. Consider the bullets as cues identifying the most important ideas in the previous chapters and where to find them. For example, in Chapter 3, one bullet says "Determine the direction of acceleration using a motion diagram (Section 2.7)." Ask yourself whether you know how to do that, and if you do not, review Section 2.7.



Physics Tool Boxes

These boxes show you the sequence of steps necessary to master a specific physics skill, such as drawing a force diagram or a bar chart. These skills are tools you will use to analyze physics processes and solve problems. They serve as bridges between real phenomena and mathematics (math is also one of the tools, but we treat it separately). If you learn to use these tools effectively, problem solving will be much easier. When you are learning a new tool, redraw all the steps in your notebook and, after that, work through the Conceptual Exercise that follows a Physics Tool Box. This process will help you practice the steps that you just learned.



Observational Experiment Tables

These tables help you learn how to observe simple experiments carefully and look for patterns. The goal of these tables is to show you where physics concepts and mathematical models come from. To find the patterns, you will need to use the tools that you learn in the Physics Tool Boxes. When working with an Observational Experiment Table, first watch the video of the experiment. Then read the description of the experiment in the left column of the table and try to analyze it without looking at the rest of the table. After you are done, compare your analysis to the analysis in the right-hand column(s) of the table and see if you agree with the described patterns. The experiment videos launch directly from the eText pages. They are also linked within the Study Area of Mastering™ Physics, via this QR code, and at https://goo.gl/s2MerO. We recommend that you bookmark this page and use it when you work with the book.

TESTING EXPERIMENT TABLE 3.7 Testing the relationship between the forces that interacting objects exert on each other

VIDEO TET 3.7

Testing experiment	Prediction	Outcome
Two people are holding spring scales that are hooked together. The scales remain horizontal during the experiment. Person 1 pulls her scale so that scale 1 reads 10 N, while person 2 just holds scale 2. Predict the reading of scale 2.  Predict the reading of scale 1 when person 2 pulls scale 2 exerting an arbitrary force.	If the pattern relating the two forces that interacting objects exert on each other (they have the same magnitudes and opposite directions) is correct, and scale 1 pulls on scale 2 exerting a force of 10 N, then scale 2 should pull on scale 1 in the opposite direction exerting a force of 10 N. Both scales will have the same reading. The same is true for the readings of the scales when scale 2 pulls on scale 1.	The experiments show that no matter who pulls on a scale, the scales have the same reading.

Conclusion

The outcome supports the pattern in the forces that two objects exert on each other during the interaction. These forces are of the same magnitude and opposite in direction.

TIP Notice that the "vector sum of the forces" mentioned in the definition at right does not mean the sum of their magnitudes. Vectors are not added as numbers; their directions affect the magnitude of the vector sum.

Tips

These short comments within the text encourage the use of particular strategies, point your attention to important details that you might otherwise miss, or warn you about specific difficulties that many students experience.

REVIEW QUESTION 3.6 Newton's second law says that the acceleration of an object is inversely proportional to its mass. However, the acceleration with which all objects fall in the absence of air is the same. How can this be?

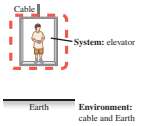
Review Questions

At the end of each section is a Review Question. The goal of these questions is to help you learn how to read a scientific text and interrogate it in a way that is similar to how physicists interrogate claims. This skill is a major component of critical thinking. After you read the question, first try to form your opinion about the answer and only after that reread the section and try to find evidence that will support or refute your opinion. Ask your instructor for the answers to Review Questions.

Problem solving

This textbook teaches you how to approach physics problem solving in a very systematic way. If you consistently follow the problem-solving strategy demonstrated in worked examples, we guarantee that by the end of the course you will be an expert problem solver. Every example has four problem-solving steps that we suggest you use when solving *any* physics problem. Start by reading the problem at least three times to completely understand the problem statement. Next, try to visualize the problem situation and draw a sketch. This is the beginning of the first step:

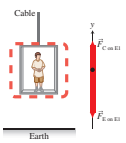
Sketch and translate



"Translate" means converting the problem's everyday language into the language of physical quantities. It is helpful to use the strategy "circle, box, underline" when trying to translate. *Circle* what is given and can be easily translated (for example, the given mass of a crash test dummy, 60 kg), *box* what needs to be found (such as the average force that an air bag and seat belt exert on the dummy), and *underline* the words that need interpretation for the translation (the word "stops" tells us that the final speed of the dummy is 0 m/s). Notice that sketching the process and representing it in different ways are important steps in solving any problem.

Testing Experiment Tables

These tables help you learn how to test patterns or explanations (many of them will be the patterns that emerged from the Observational Experiment Tables). Your procedure with these tables is different. First, read the description of the experiment in the left column, then try to use the pattern or explanation being tested to predict the outcome of the experiment. Only then should you watch the video or read about the outcome in the far right column.

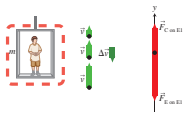


Summary

A **system** is circled in a sketch of a process. Other objects that interact with the system are called the **environment**. (Sections 3.1 and 3.5)

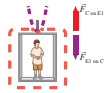
The **force** that one object exerts on another characterizes an interaction between the two objects (a pull or a push). The unit of force is the newton (N); $1\text{ N} = (1\text{ kg})(1\text{ m/s}^2)$. (Sections 3.1 and 3.5)

A **force diagram** represents the forces that external objects exert on the system. The arrows in the diagram point in the directions of the forces, and their lengths indicate the relative magnitudes of the forces. (Sections 3.1 and 3.2)



$\vec{F}_{E \text{ on } O}$ Interacting objects

A force is denoted by the symbol $\vec{F}$ with two subscripts indicating the object that is exerting the force and the system object.



Newton's first law of motion If no other objects exert forces on a system or if the forces exerted on the system add to zero, then the system continues moving at constant velocity (as seen by observers in inertial reference frames). (Section 3.4)

Newton's second law The acceleration a_S of a system is proportional to the sum of the forces that other objects exert on the system and inversely proportional to its mass m. (Section 3.5)

$$\vec{a}_S = \frac{\Sigma \vec{F}_{\text{on S}}}{m_S} = \frac{\vec{F}_{1 \text{ on S}} + \vec{F}_{2 \text{ on S}} + \cdots}{m_S} \quad \text{Eq. (3.6)}$$

Newton's third law Two objects exert equal-magnitude and opposite direction forces of the same type on each other. (Section 3.8)

$$\vec{F}_{1 \text{ on } 2} = -\vec{F}_{2 \text{ on } 1} \quad \text{Eq. (3.9)}$$

The **gravitational force** $\vec{F}_{E \text{ on } O}$ that Earth exerts on an object of mass m when on or near Earth's surface depends on the gravitational coefficient g of Earth. If on or near another planet or the Moon, the gravitational coefficient near those objects is different. (Section 3.6)

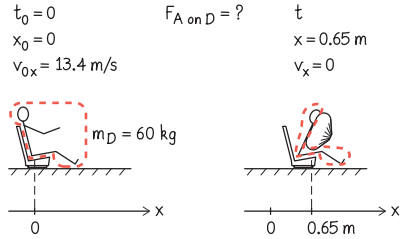
Magnitude

$$F_{E \text{ on } O} = m_O g \quad \text{Eq. (3.8)}$$

where

$g = 9.8\text{ m/s}^2 = 9.8\text{ N/kg}$

when the object is on or near Earth's surface.

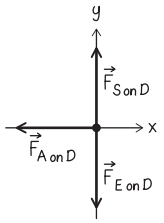


Chapter summaries

The summary at the end of each chapter helps you reflect on what you learned. Compare different representations of the same idea and try to find anything you might have missed or misunderstood. Do you understand the connections? Can you write the mathematics illustrated by a diagram? This process is the best strategy to make sure you did not miss anything.

EXAMPLE 3.9 Force exerted by air bag on driver during collision

A 60-kg crash test dummy moving at 13.4 m/s (30 mi/h) stops during a collision in a distance of 0.65 m. Estimate the magnitude of the average force that the air bag and seat belt exert on the dummy.



Sketch and translate We sketch and label the situation as shown below, choosing the crash test dummy as the system. The positive x-direction is in the direction of motion, and the origin is at the position of the dummy at the start of the collision.

Simplify and diagram

Here you will make necessary simplifications and choose a productive physics representation (from your Tool Box). Determine how you can simplify the situation. How will you model the object of interest? What interactions can you neglect? You will learn a new representation in nearly every chapter; thus the choice of a productive one is key to solving the problem.

Simplify and diagram We model the dummy D as a point-like object and assume that the primary force exerted on the dummy while stopping is due to the air bag and seat belt's $\vec{F}_{\text{A on D}}$, shown in the force diagram. We can ignore the downward gravitational force that Earth exerts on the dummy $\vec{F}_{\text{E on D}}$ and the upward force that the car seat exerts on the dummy $\vec{F}_{\text{S on D}}$ since they add to zero and do not contribute to the acceleration.

Represent mathematically

In this step you will use the physics representation from the step above to construct the mathematical representation of the same situation. No numbers are needed here, only symbols of physical quantities. The goal of this step is to work with the mathematical representations to isolate the variable that you need to solve for. By representing the situation using these multiple methods and learning to translate from one type of representation to another, you will start giving meaning to the abstract symbols used in the mathematical description of the situation.

Represent mathematically To determine the dummy's acceleration, we use kinematics:

$$a_x = \frac{v_x^2 - v_{0x}^2}{2(x - x_0)}$$

Once we have the dummy's acceleration, we apply the x-component form of Newton's second law to find the force exerted by the air bag and seat belts on the dummy:

$$a_x = \frac{F_{\text{A on D}\,x}}{m_{\text{D}}} = \frac{-F_{\text{A on D}}}{m_{\text{D}}} = -\frac{F_{\text{A on D}}}{m_{\text{D}}}$$

$$\Rightarrow F_{\text{A on D}} = -m_{\text{D}} a_x$$

Solve and evaluate

Finally, you will plug the values of the physical quantities into the equation found in the step above (do not forget the units!) and solve for the variable you boxed in the first step. When you obtain a number, your job is not done—you need to evaluate your answer, or ask yourself whether your answer is reasonable. You will learn three major strategies for performing this evaluation in this book.

Solve and evaluate We know that $v_{0x} = +13.4\ \text{m/s}$ and $v_x = 0$ (the dummy has stopped). The initial position of the dummy is $x_0 = 0$ and the final position is $x = 0.65\ \text{m}$. The acceleration of the dummy while in contact with the air bag and seat belt is

$$a_x = \frac{0^2 - (13.4\ \text{m/s})^2}{2(0.65\ \text{m} - 0\ \text{m})} = -138\ \text{m/s}^2$$

Thus, the *magnitude* of the average force exerted by the air bag and seat belt on the dummy is

$$F_{\text{A on D}} = -(60\ \text{kg})(-138\ \text{m/s}^2) = 8300\ \text{N}$$

This force $[\,8300\ \text{N}(1\ \text{lb}/4.45\ \text{N}) = 1900\ \text{lb}\,]$ is almost 1 ton. Is this estimate reasonable? The magnitude is large, but experiments with crash test dummies in the real world are consistent with a force this large in magnitude, a very survivable collision.

Try to solve the example problems in the chapters by using this four-step strategy without looking at the solution. After finishing, compare your solution to the one described in the book. Then do the "Try it yourself" part of the example problem and compare your answer to the book's answer. If you are still having trouble, use the same strategy to actively solve other example problems in the text or problems from the Active Learning Guide (if you are using that companion book). Uncover the solutions to these worked examples only after you have tried to complete the problem on your own. Then follow the same process on the homework problems assigned by your instructor.

In addition to the full worked examples, the book provides Conceptual Exercises and Quantitative Exercises. These have fewer steps: "Sketch and translate" and "Simplify and diagram" in the Conceptual Exercises, and "Represent mathematically" and "Solve and evaluate" in the Quantitative Exercises.

Summary

We are confident that this book will act as a useful companion in your study of physics and that you will take from the course not just the knowledge of physics but also an understanding of the process of science that will help you in all your scientific endeavors. Learning physics through the approach used in this book builds a deeper understanding of physics concepts and an improved ability to solve difficult problems compared to traditional learning methods. In addition, you will learn to reason scientifically and be able to transfer those reasoning skills to many other aspects of your life.

2

Kinematics: Motion in One Dimension

When you drive, you are supposed to follow the three-second tailgating rule. When the car in front of you passes a sign at the side of the road, your car should be far enough behind it that it takes you 3 s to reach the same sign. In this chapter, we will learn the physics behind the three-second rule.

- **What is a safe following distance between your car and the car in front of you?**
- **Can you be moving and not moving at the same time?**
- **Why do physicists say that an object thrown upward is falling?**

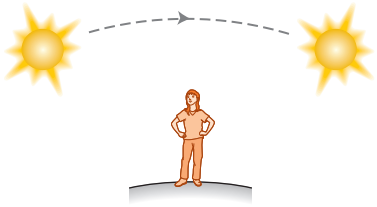
SCIENTISTS OFTEN ASK questions about things that most people accept as "just the way it is." For example, in the northern hemisphere, there are more hours of daylight in June than in December, whereas in the southern hemisphere, the opposite is true. Scientists want explanations for such simple phenomena. In this chapter, we will learn to describe a phenomenon that we encounter every day but rarely question—motion.

BE SURE YOU KNOW HOW TO:

- Decide when an object can be modeled as a point-like object (Section 1.2).
- Use significant digits in calculations (Section 1.3).

2.1 What is motion?

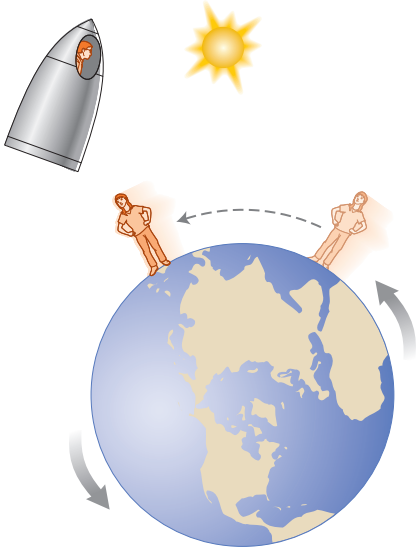
Imagine you are a passenger in a car. You see your friend standing on the sidewalk and wave at her, turning your head to look at her while driving past her. She too turns her head as she waves back. We turn our heads to follow a moving object, so it is not surprising that your friend turns her head—you are in a moving car. But why do *you* turn your head? After all, your friend is standing still on the sidewalk. However, from your perspective, she is moving away from you. This example helps us understand a very important idea: **different observers see the same motion differently**. In other words, motion is relative to the *observer*, the person who is describing the motion. So who is moving in this scenario, you or your friend? The answer is that it depends on who is the observer. The driver of your car, for example, sees you (a passenger in the car) as not moving.



This example shows us that when describing motion we need to specify both the object whose motion we are describing (the **object of interest**) and the person who is doing the describing (the **observer**).

Motion is a change in an object's position relative to a given observer during a certain time interval. Without identifying the observer, it is impossible to say whether the object of interest moved. Physicists say *motion is relative,* meaning that the motion of any object of interest depends on the point of view of the observer.

FIGURE 2.1 Motion is relative. Two observers explain the motion of the Sun relative to Earth differently.



(a)

An observer on Earth sees the Sun move in an arc across the sky.

(b)

An observer in a spaceship sees the person on Earth as rotating under a stationary Sun.

What makes the idea of relative motion confusing at first is that people intuitively use Earth as the object of reference—the object with respect to which they describe motion. If an object does not move with respect to Earth, many people would say that the object is not moving. That is why it took scientists thousands of years to understand why Earth has days and nights. An observer on Earth uses Earth as the object of reference and sees the Sun moving in an arc across the sky (**Figure 2.1a**). An observer on a distant spaceship, however, sees Earth rotating on its axis so that different parts of its surface face the Sun at different times (Figure 2.1b).

Reference frames

Specifying the observer before describing the motion of an object of interest is an extremely important part of constructing what physicists call a **reference frame**. **A reference frame includes an object of reference, a coordinate system with a scale for measuring distances, and a clock to measure time.** If the object of reference is large and cannot be considered a point-like object, it is important to specify where on the object of reference the origin of the coordinate system is placed. For example, if you want to describe the motion of a bicyclist and choose your object of reference to be Earth, you place the origin of the coordinate system at Earth's surface, not its center.

Modeling motion

When we model objects, we make simplified assumptions in order to analyze complicated situations. Just as we simplified an object to model it as a point-like object in Chapter 1, we can also simplify a process involving motion. What is the simplest way an object can move?

Imagine that you haven't ridden a bike in a while. You probably wouldn't start by attempting a turn; instead, you would ride in a straight line. This kind of motion is called **linear motion** or **one-dimensional motion**.

Linear motion is a model of motion that assumes that an object, considered as a point-like object, moves along a straight line.

For example, suppose we want to model a car's motion along a straight stretch of highway. We can assume that the car is a point-like object (it is small compared to the length of the highway) and the motion is linear motion (the highway is long and straight).

REVIEW QUESTION 2.1 What does the statement "Motion is relative" mean?

2.2 A conceptual description of motion

To describe linear motion more precisely, we start by devising a visual representation. Consider Observational Experiment **Table 2.1**, in which a bowling ball rolls on a smooth floor.

OBSERVATIONAL EXPERIMENT TABLE 2.1  **Using dots to represent motion**

VIDEO OET 2.1

Observational experiment	Analysis
Experiment 1. You push a bowling ball (the object of interest) and let it roll on a smooth linoleum floor. Each second, you place a beanbag beside the bowling ball. The beanbags are evenly spaced.	The dots in this diagram represent the positions of the beanbags you placed each second as the bowling ball slowly rolled on the floor. ● ● ● ●
Experiment 2. You repeat Experiment 1, but you push the ball harder before you let it roll. The beanbags are farther apart but are still evenly spaced.	The dots in this diagram represent the positions of the beanbags, which are still evenly spaced but separated by a greater distance than the bags in Experiment 1. ● ● ●
Experiment 3. You push the bowling ball and let it roll on a carpeted floor instead of a linoleum floor. The distance between the beanbags decreases as the ball rolls.	The dots in this diagram represent the decreasing distance between the beanbags as the ball rolls on the carpet. ● ● ● ●
Experiment 4. You roll the ball on the linoleum floor and gently and continually push on it with a board. The distance between the beanbags increases as the pushed ball rolls.	The dots in this diagram represent the increasing distance between beanbags as the ball is continually pushed across the linoleum floor. ● ● ● ●

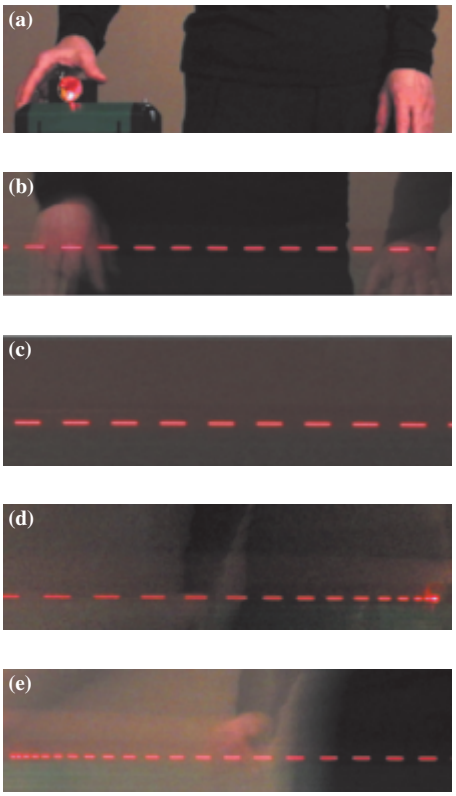
Pattern

- The spacing of the dots allows us to visualize the motion of the object of interest.
- When the object travels without speeding up or slowing down, the dots are evenly spaced.
- When the object slows down, the dots get closer together.
- When the object moves faster and faster, the dots get farther apart.

Motion diagrams

In the experiments in Table 2.1, we used beanbags as an approximate record of where the ball was located as time passed to help us visualize the motion of the ball. Let's now use blinking LEDs to help us more precisely visualize motion, this time of

FIGURE 2.2 Long-exposure photographs of a moving cart with a blinking LED.



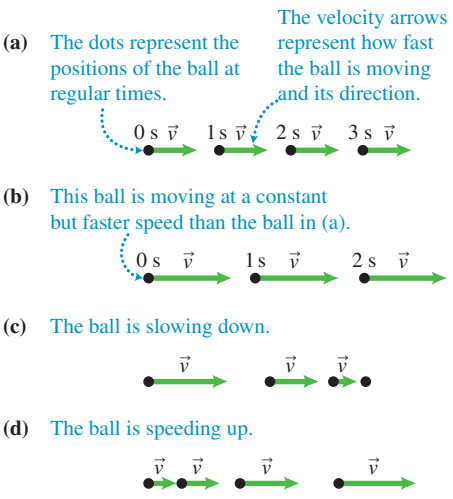


FIGURE 2.3 Motion diagrams represent the types of motion shown in Table 2.1.

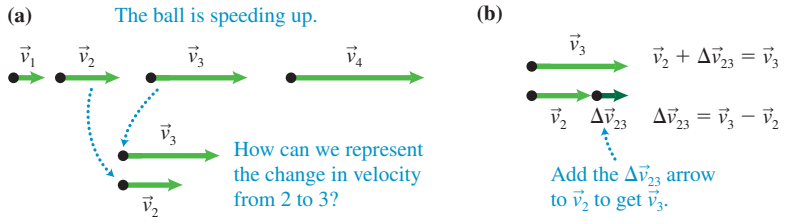
a cart. **Figure 2.2a** shows a cart with an attached blinking LED (on for 31 ms, then off for 31 ms). Figure 2.2b is a long-exposure photo of the cart as it is moving on a horizontal surface at steady speed, similar to the situation in Experiment 1 of Table 2.1. In Figure 2.2c, the cart is moving faster. Next, in Figure 2.2d, the moving cart is being pushed in the direction opposite to its motion until it stops. In Figure 2.2e, the cart is being pushed from rest and moves faster and faster.

As you can see, the light traces in the four photos clearly illustrate the different types of motion of the cart. The same-length light traces in Figure 2.2b indicate that the cart moved the same distance each time the LED light was on (that is, was traveling at a steady speed), while the longer traces of Figure 2.2c show that the cart covered a longer distance during each light blink. In Figure 2.2d, the traces get shorter as the cart was slowing down and turn into a point when the cart stopped. In Figure 2.2e, the traces get longer as the cart was speeding up.

These LED photos help us construct a new representation of motion that has more information than the dot diagrams: this representation is called a **motion diagram**. We draw dots to represent the positions of the cart and, instead of the traces of light, we draw arrows to indicate the cart's direction of motion. The length of each arrow shows how fast the cart was moving at the location of that dot. These arrows are called **velocity arrows**.

Figure 2.3 shows different types of motion represented with dots and velocity arrows. Notice the small arrow above each letter v (for velocity) in the figures. The arrow indicates that this characteristic of motion has a direction as well as a magnitude. Remember from Chapter 1 that such quantities are called *vector quantities*.



Velocity change arrows

In Experiment 4 in Table 2.1 the bowling ball was moving increasingly faster while being pushed. The velocity arrows in the motion diagram in Figure 2.3d thus are increasingly longer. We can represent this change by drawing a **velocity change ($\Delta\vec{v}$) arrow**. The Δ (delta) means a change in whatever quantity follows the Δ, a change in $\vec{v}$ in this case. The $\Delta\vec{v}$ doesn't tell us the exact increase or decrease in the velocity; it only indicates a qualitative difference between the velocities at two adjacent points in the diagram.

In **Figure 2.4a** we have redrawn the diagram shown in Figure 2.3d. For illustration purposes only, we number the $\vec{v}$ arrows for each position: $\vec{v}_1$, $\vec{v}_2$, $\vec{v}_3$, etc. To draw the velocity change arrow as the ball moves from position 2 to position 3 in Figure 2.4a, we place the arrow $\vec{v}_3$ directly above the arrow $\vec{v}_2$, as shown. The $\vec{v}_3$ arrow is longer than the $\vec{v}_2$ arrow. This tells us that the object was moving faster at position 3 than at position 2. To visualize the change in velocity, we need to think about how arrow $\vec{v}_2$ can be turned into $\vec{v}_3$. We can do it by placing the tail of a velocity change arrow $\Delta\vec{v}_{23}$ at the head of $\vec{v}_2$ so that the head of $\Delta\vec{v}_{23}$ makes $\vec{v}_2 + \Delta\vec{v}_{23}$ the same length as $\vec{v}_3$ (Figure 2.4b). Since they are the same length and point in the same direction, the two vectors $\vec{v}_2 + \Delta\vec{v}_{23}$ and $\vec{v}_3$ are equal:

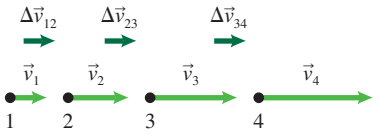
$$\vec{v}_2 + \Delta\vec{v}_{23} = \vec{v}_3$$

FIGURE 2.4 Determining the magnitude and direction of the velocity change arrow in a motion diagram.

Note that if we move $\vec{v}_2$ to the other side of the equation, then

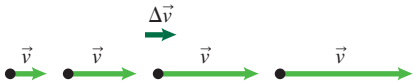
$$\Delta\vec{v}_{23} = \vec{v}_3 - \vec{v}_2$$

Thus, $\Delta\vec{v}_{23}$ is the difference of the third velocity arrow and the second velocity arrow—the change in velocity between position 2 and position 3.



Making a complete motion diagram

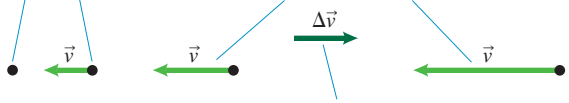
We now place the $\Delta\vec{v}$ arrows above and between the dots in our diagrams where the velocity change occurred (see **Figure 2.5a**). The dots in these more detailed motion diagrams indicate the object's position at equal time intervals; velocity arrows and velocity change arrows are also included. **A $\Delta\vec{v}$ arrow points in the same direction as the $\vec{v}$ arrows when the object is speeding up; the $\Delta\vec{v}$ arrow points in the opposite direction of the $\vec{v}$ arrows when the object is slowing down.** When velocity changes by the same amount during each consecutive time interval, the $\Delta\vec{v}$ arrows for each interval are the same length. In such cases we need only one $\Delta\vec{v}$ arrow for the entire motion diagram (see Figure 2.5b).



Physics Tool Box 2.1 summarizes the procedure for constructing a motion diagram. Notice that in the experiment represented in this diagram, the object is moving from right to left and slowing down.

FIGURE 2.5 Two complete motion diagrams, including position dots, $\vec{v}$ arrows, and $\Delta\vec{v}$ arrows.

(a) A motion diagram showing the velocity change for each consecutive position change



(b) When the velocity change is constant from time interval to time interval, we need only one $\Delta\vec{v}$ for the diagram.

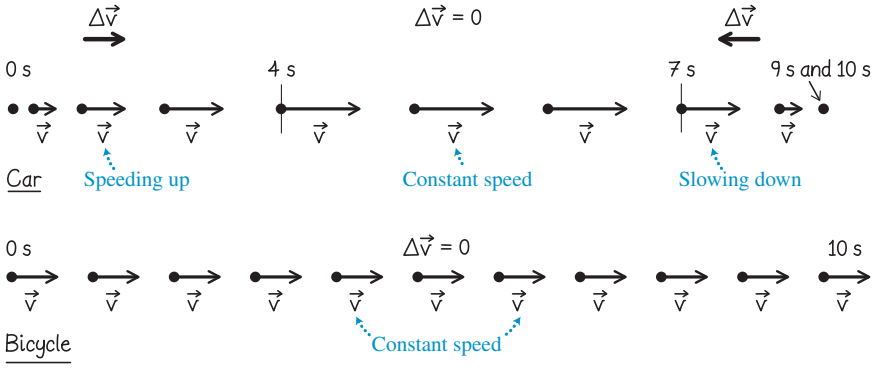
PHYSICS TOOL BOX 2.1 Constructing a motion diagram

1. Draw dots to represent the position of the object with respect to the observer at equal time intervals.
2. Point velocity arrows in the direction of motion and draw their relative lengths to indicate approximately how fast the object is moving.
3. Draw a velocity change arrow to indicate how the velocity arrows are changing between adjacent positions.

Conceptual Exercise 2.1 will help you practice representing motion with motion diagrams. When working on Conceptual Exercises, first visualize the situation, then draw a sketch, and finally construct a physics representation (in this case, a motion diagram).

TIP When drawing a motion diagram, always specify the position of the observer.

CONCEPTUAL EXERCISE 2.1 Driving in the city



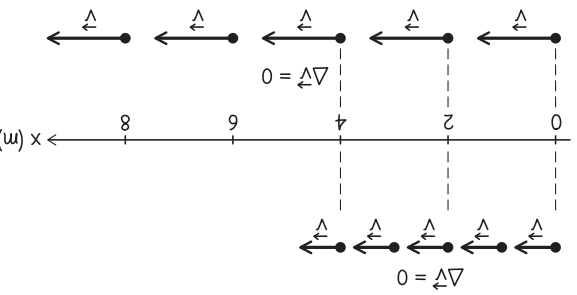
A car at rest at a traffic light starts moving faster and faster when the light turns green. The car reaches the speed limit in 4 s, continues at the speed limit for 3 s, then, approaching a second, red, traffic light, slows down and stops in 2 s. At the light, the car waits for 1 s until it turns green. Meanwhile, a cyclist approaching the first green light keeps moving without slowing down or speeding up. She reaches the second stoplight just as it turns green. Draw a motion diagram for the car and another for the bicycle as seen by an observer on the ground. If you place one diagram below the other, it will be easier to compare them.

Sketch and translate Visualize the motion for the car and for the bicycle as seen by the observer on the ground. The car and the bicycle are our objects of interest.

The motion of the car has four distinct parts:

1. starting at rest and moving faster and faster for 4 s;
2. moving at a constant rate for 3 s;
3. slowing down to a stop for 2 s; and
4. sitting at rest for 1 s.

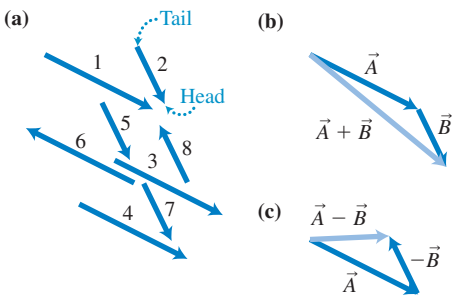
(CONTINUED)



The bicycle moves at a constant rate with respect to the ground for the entire time.

Simplify and diagram We model the car and the bicycle as point-like objects (dots). In each motion diagram, there are 11 dots, one for each second of time (including one for time 0). The last two dots for the car are on top of each other since the car is at rest from time = 9 s to time = 10 s. The dots for the bicycle are evenly spaced.

Try it yourself Two bowling balls are rolling along a linoleum floor. One of them is moving twice as fast as the other. At time 0, they are next to each other on the floor. Construct motion diagrams for each ball during a time interval of 4 s, as seen by an observer on the ground. Indicate on the diagrams the locations at which the balls were next to each other at the same time. What are the possible mistakes that a student could make when doing this exercise?



Answer See the figure at left. The balls are side by side only at time 0—the first dot for each ball. It looks like they are side by side when at the 2-m position, but the slower ball is at the 2-m position at 2 s and the faster ball is there at 1 s. Similar reasoning applies for the 4-m positions—the balls reach that point at different times.

REVIEW QUESTION 2.2 Is the following statement true? "If an object's velocity change arrows point to the left, it is slowing down." Support your answer with examples.

2.3 Operations with vectors

FIGURE 2.6 Using arrows to represent vectors.

Physics Tool Box 2.1 tells you to determine the direction of a $\Delta\vec{v}$ arrow on a motion diagram. To do this, you need to know either how to add vectors (the operation $\vec{v}_2 + \Delta\vec{v}_{23} = \vec{v}_3$ in Figure 2.4) or how to subtract them (the operation $\Delta\vec{v}_{23} = \vec{v}_3 - \vec{v}_2$ in Figure 2.4). Here we discuss these operations in more detail. To start, we first consider more simple vector operations. Carefully examine **Figure 2.6**, which shows eight arrows of different lengths and directions representing vectors. The length of each arrow is the vector's magnitude, in any units you choose, and the orientation of each vector is determined by the direction of the arrow. Each vector has a *tail* (the point where it originates) and a *head* (the tip of the arrow). Which arrows represent the same vector? You see that arrows 1, 3, and 4 have the same length and the same direction: they therefore represent the same vector, $\vec{A}$. Arrows 2, 5, and 7 represent a different vector, vector $\vec{B}$. From this exercise we see that moving the vector parallel to itself will not change the vector. What about arrows 6 and 8? They have the same length as $\vec{A}$ and $\vec{B}$, respectively, but they point in the opposite directions. In this case, we say that vector 6 is $-\vec{A}$, the *negative* of vector $\vec{A}$, and vector 8 is $-\vec{B}$. The minus sign is used to mean that **$-\vec{A}$ has the same length as $\vec{A}$ but points in the opposite direction.**

Now that we know how to move vectors around and draw the negative of a vector, we can explore how to add and subtract vectors. What rules of vector addition and subtraction can you infer by analyzing the examples shown in Figure 2.6b (addition, $\vec{A} + \vec{B}$) and Figure 2.6c (subtraction, $\vec{A} - \vec{B}$)? Spend a few moments thinking about this before reading the following explanation of the rules.

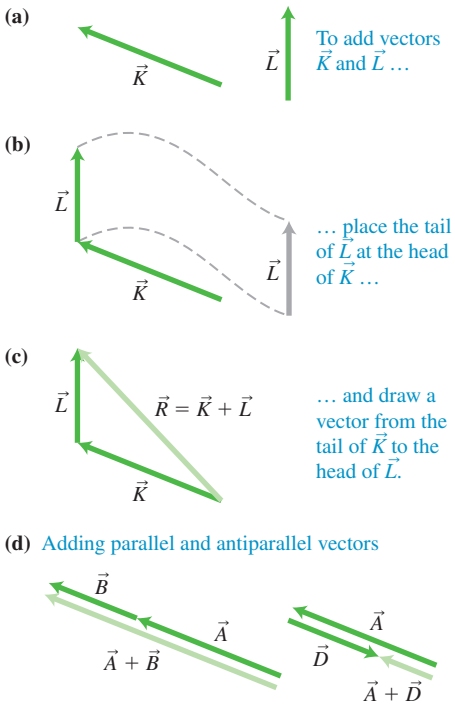
Adding vectors

Suppose we want to graphically add the two vectors $\vec{K}$ and $\vec{L}$ shown in **Figure 2.7a**. We can move a vector from one location to another as long as we do not change its magnitude or direction; therefore, we can place the tail of vector $\vec{L}$ at the head of $\vec{K}$, as shown in Figure 2.7b, without changing $\vec{L}$. Next, we draw another vector $\vec{R}$ from the tail of $\vec{K}$ to the head of $\vec{L}$, as shown in Figure 2.7c, to represent the result of the addition of the vectors $\vec{K}$ and $\vec{L}$. We can write the *resultant vector* (vector sum) as a mathematical equation: $\vec{R} = \vec{K} + \vec{L}$. As you can see in Figure 2.7c, the magnitude of the vector sum is not in general equal to the sum of the magnitudes of $\vec{K}$ and $\vec{L}$. However, there are two special cases, as Figure 2.7d shows:

- When two vectors are parallel and point in the same direction, the addition is much easier: the magnitude of the resultant vector equals the sum of the magnitudes of the vectors being added.
- When two vectors are parallel but point in opposite directions (called antiparallel), the magnitude of the resultant vector equals the absolute value of the difference in the magnitudes of the vectors being added.

If you need to add more vectors, follow the same procedure of "tail to head" for all of them, and then draw the resultant vector. For accurate results in graphical addition, draw carefully using a ruler and a protractor.

FIGURE 2.7 Graphical vector addition.



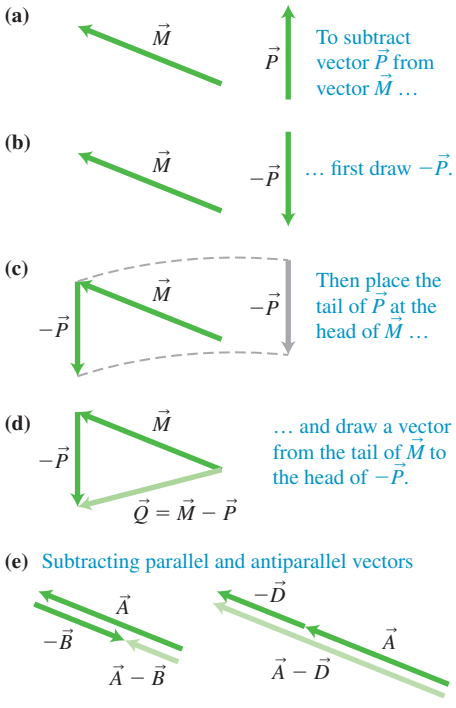


FIGURE 2.8 Graphical vector subtraction.

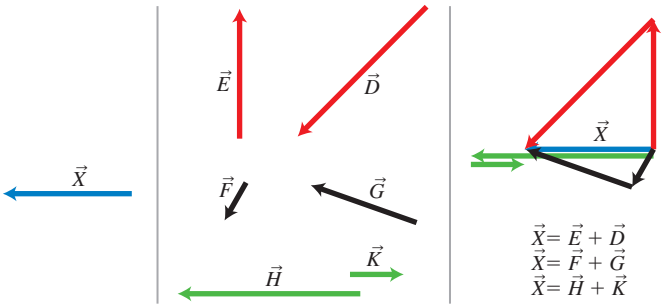
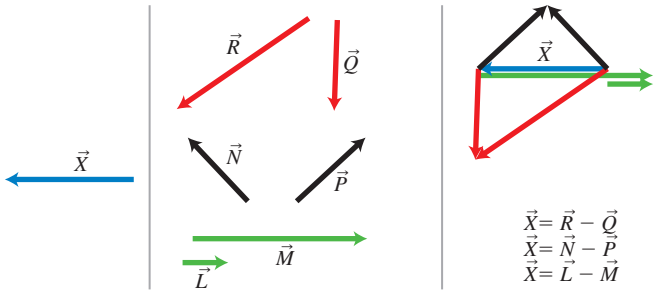


Subtracting vectors

Suppose we now want to subtract vector $\vec{P}$ from vector $\vec{M}$, shown in **Figure 2.8a**. You can interpret the operation of subtracting vector $\vec{P}$ from vector $\vec{M}$ as the *addition* of vector $-\vec{P}$ and vector $\vec{M}$. The vector equation is $\vec{Q} = \vec{M} - \vec{P} = \vec{M} + (-\vec{P})$. As Figure 2.8 shows, we therefore need to draw the vector $-\vec{P}$ first, and then proceed with graphical vector addition of $-\vec{P}$ and $\vec{M}$. Figure 2.8e shows the subtraction of parallel and antiparallel vectors. This part is relevant to determining the direction and magnitude of the $\Delta\vec{v}$ vector on a motion diagram.

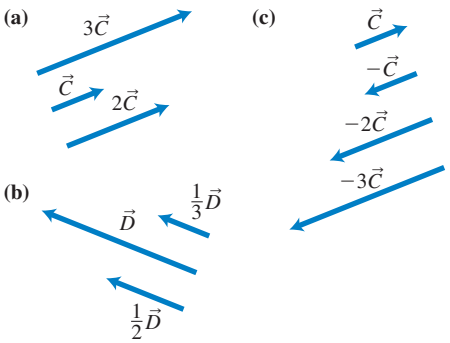


CONCEPTUAL EXERCISE 2.2 **Multiple ways to build vector $\vec{X}$**

Vector $\vec{X}$ is 3 cm long and points west. (a) Draw three different combinations of two vectors whose addition gives vector $\vec{X}$. One of the combinations should have antiparallel vectors. (b) Draw three different combinations of two vectors whose subtraction gives vector $\vec{X}$. One of the combinations should have parallel vectors.

Sketch and translate (a) We draw vector $\vec{X}$ and think of possible combinations of two vectors that we can add to get $\vec{X}$. Using the method for graphical addition, we know that the sum $\vec{X}$ must span from the tail of one vector to the head of the other when the two vectors are placed head to tail. The figure below shows three possible combinations. $\vec{H}$ and $\vec{K}$ are antiparallel vectors whose sum is $\vec{X}$.

(b) If the subtraction of one vector from another gives $\vec{X}$, then we know that the first vector plus $\vec{X}$ gives the second vector. We can therefore draw any vector for the first vector and then add $\vec{X}$ to it to get the second vector. The figure below shows three possible combinations. $\vec{L}$ and $\vec{M}$ are parallel vectors whose difference is $\vec{X}$.



Try it yourself Examine Figure 2.4. Where in this figure do we use vector addition and where do we use vector subtraction?

Answer The velocity arrow $\vec{v}_3$ is a vector that is the sum of the two vectors $\vec{v}_2$ and $\Delta\vec{v}_{23}$: $\vec{v}_3 = \vec{v}_2 + \Delta\vec{v}_{23}$; the velocity change arrow is a vector $\Delta\vec{v}_{23}$ that is the result of subtraction of vector $\vec{v}_2$ from vector $\vec{v}_3$: $\Delta\vec{v}_{23} = \vec{v}_3 - \vec{v}_2$.

Multiplying a vector by a scalar

In addition to vector addition and subtraction, there is another operation with vectors that you will need when studying physics. It involves multiplying a vector by a positive or a negative number (a scalar quantity)—for example, finding vector $2\vec{C}$ when vector $\vec{C}$ is known. **Figure 2.9a** shows the result of this operation. Vector $2\vec{C}$ is twice as long as $\vec{C}$, or equal to the sum of two $\vec{C}$ vectors, and points in the same direction. Vector $3\vec{C}$ is three times as long, or equal to the sum of three $\vec{C}$ vectors, and points in the same direction. Figure 2.9b shows the result of dividing vector $\vec{D}$ by 2 and by 3. We see that the result is equal to multiplying vector $\vec{D}$ by $1/2$ and $1/3$, respectively (the vector is one-half or one-third of the length of vector $\vec{D}$). Finally, if you need to multiply vector $\vec{C}$ by a negative number, for example -2 or -3, you need to first draw vector $-\vec{C}$, as we learned above, and then multiply it by 2 or 3 (Figure 2.9c). In general, **when you multiply a vector by a scalar, the result is a vector parallel or antiparallel to the original vector whose magnitude equals the product of the magnitude of the original vector and the magnitude of the scalar.** [Note that if the scalar in this operation has units, the resulting vector has units that are the product of the original vector units and the units of the scalar.]

FIGURE 2.9 Multiplying a vector by a scalar.

REVIEW QUESTION 2.3 Eugenia says that to find the $\Delta\vec{v}$ arrow on a motion diagram you need to subtract vectors. Alan says that you need to add vectors. Both are right. How can this be? Explain and show examples.

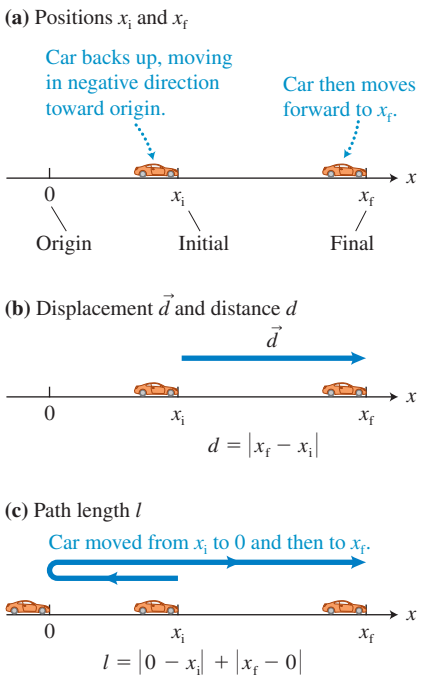
2.4 Quantities for describing motion

A motion diagram helps represent motion qualitatively. To analyze situations more precisely, for example, to determine how far a car will travel after the brakes are applied, we need to describe motion quantitatively. In this section, we devise some of the quantities we need to describe linear motion.

Time and time interval

People use the word "time" to mean the reading on a clock and how long a process takes. Physicists distinguish between these two meanings with different terms:

Time and time interval *Time* (clock reading) t is the reading on a clock or some other time-measuring instrument. *Time interval* $(t_2 - t_1)$ or Δt is the difference between two times. In the SI system (metric units), the unit of both time and time interval is the second. Other units are minutes, hours, days, and years. Time and time interval are both scalar quantities.



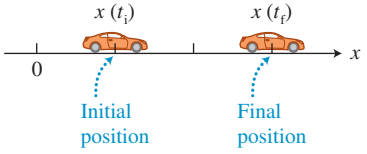
Position, displacement, distance, and path length

We also need to precisely define four quantities that describe the location and motion of an object:

Position, displacement, distance, and path length The *position* of an object is its location with respect to a particular coordinate system (usually indicated by x or y). The *displacement* of an object, usually indicated by $\vec{d}$, is a vector that starts from an object's initial position and ends at its final position. The magnitude (length) of the displacement vector is called the *distance d.* The *path length l* is how far the object moved as it traveled from its initial position to its final position. Imagine laying a string along the path the object took. The length of the string is the path length.

Figure 2.10a shows a car's initial position x_i at initial time t_i. The car first backs up (moving in the negative direction) toward the origin of the coordinate system at $x = 0$. The car stops and then moves in the positive x-direction to its final position x_f. Notice that the *initial position* and the *origin* of a coordinate system are not necessarily the same point! The displacement $\vec{d}$ for the whole trip is a vector that points from the starting position at x_i to the final position at x_f (Figure 2.10b). The distance for the trip is the magnitude of the displacement (always a positive value). The path length l is the distance from x_i to 0 plus the distance from 0 to x_f (Figure 2.10c). Note that the path length does not equal the distance.

FIGURE 2.10 Position, displacement, distance, and path length for a short car trip.



TIP Sometimes we use the subscripts 1, 2, and 3 for times and the corresponding positions to communicate a sequence of different and distinguishable stages in any process, and sometimes we use the subscripts i (initial) and f (final) to communicate the sequence. Subscripts i and f mean the beginning and end of our observations, not the beginning and end of the process.

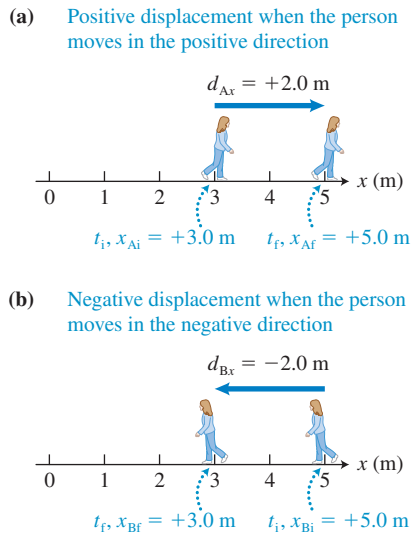
Scalar component of displacement for motion along one axis

To describe linear motion quantitatively we first specify a reference frame. For simplicity we can point one coordinate axis either parallel or antiparallel to the object's direction of motion. For linear motion, we need only one coordinate axis to describe the object's changing position. In the example of the car trip, at the initial time t_i the car is at position $x(t_i)$, and at the final time t_f the car is at $x(t_f)$ (**Figure 2.11**). The notation $x(t)$

FIGURE 2.11 Indicating an object's position at a particular time t, for example, $x(t)$.

means the position x is a function of clock reading t (spoken "x of t"), not x multiplied by t. When we need to note a specific value of position x at a specific clock reading t_1, instead of writing $x(t_1)$, we will write x_1, keeping in mind that 1 is a shortcut for time t_1. The same applies to x_i, x_f, etc. The vector that points from the initial position x_i to the final position x_f is the **displacement**.

The quantity that we determine through the operation $x_f - x_i$ is called the ***x*-scalar component of the displacement** vector and is abbreviated d_x (usually we drop the term "scalar" and just call this the ***x*-component of the displacement**). **Figure 2.12a** shows that the initial position of person A is $x_{Ai} = +3.0$ m and the final position is $x_{Af} = +5.0$ m; thus the x-component of the person's displacement is



$$d_{Ax} = x_{Af} - x_{Ai} = (+5.0\text{ m}) - (+3.0\text{ m}) = +2.0\text{ m}$$

The displacement is positive since the person moved in the positive x-direction. In Figure 2.12b, person B moved in the negative direction from the initial position of +5.0 m to the final position of +3.0 m; thus the x-component of displacement of the person is negative:

$$d_{Bx} = x_{Bf} - x_{Bi} = (+3.0\text{ m}) - (+5.0\text{ m}) = -2.0\text{ m}$$

Distance is always positive, as it equals the absolute value of the displacement $|x_f - x_i|$. In the example above, the displacements for A and B are different, but the distances are both +2.0 m.

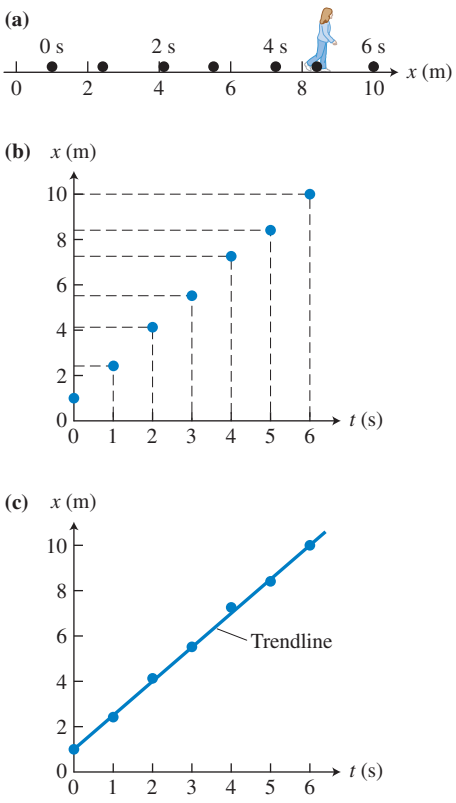


FIGURE 2.12 The x-component of displacement is (a) positive; (b) negative.

Significant digits

Note that in Figure 2.12 the positions were written as +3.0 m and +5.0 m. Could we have written them instead as +3 m and +5 m, or as +3.00 m and +5.00 m? The thickness of a human body from the back to the front is about 0.2 m (20 cm). Thus, we should be able to measure the person's location at one instant of time to within about 0.1 m but not to 0.01 m (1 cm). Thus, the locations can reasonably be given as +3.0 m, which implies an accuracy of ±0.1 m. (For more on significant digits, see Chapter 1.)

FIGURE 2.13 Constructing a kinematics position-versus-time graph.

REVIEW QUESTION 2.4 Jade went hiking between two camps that were separated by about 10 km. She hiked approximately 16 km to get from one camp to the other. Translate 10 km and 16 km into the language of physical quantities.

2.5 Representing motion with data tables and graphs

So far, we have learned how to represent linear motion with motion diagrams. In this section, we will learn to represent linear motion with data tables and graphs.

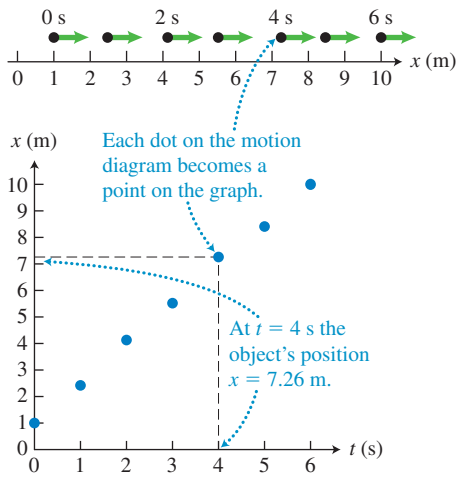
Imagine your friend (the object of interest) walking across the front of your classroom. To record her position, you drop a beanbag on the floor at her position each second (**Figure 2.13a**). The floor is the object of reference. The origin of the coordinate system is 1.00 m from the first beanbag, and the position axis points in the direction of motion. **Table 2.2** shows each bag's position and the corresponding clock reading. Do you see a pattern in the table's data? One way to determine if there is a pattern is to plot the data on a graph (Figure 2.13b). This graph is called a **kinematics position-versus-time graph**. In physics, the word **kinematics** means description of motion. Kinematics graphs contain more precise information about an object's motion than motion diagrams can.

Time t is usually considered to be the independent variable, as time progresses even if there is no motion, so the horizontal axis will be the t-axis. Position x is the dependent variable (position changes with time), so the vertical axis will be the x-axis.

Plot the data in each row in Table 2.2 on the axes. Each point on the horizontal axis represents a time (clock reading). Each point on the vertical axis represents the position of a beanbag. When we draw lines through these points and perpendicular to the axes, they intersect at a single location—a dot on the graph that simultaneously represents a time and the corresponding position of the object. This dot *is not* a location in real space but rather a representation of the position of the beanbag at a specific time.

Is there a trend in the locations of the dots on the graph? We see that the position increases as the time increases. This makes sense. We can draw a smooth best-fit curve that passes as close as possible to the data points—a **trendline** (Figure 2.13c). It looks like a straight line in this particular case—the position is linearly dependent on time.

TABLE 2.2 Time-position data for linear motion



Clock reading (time)	Position
$t_0 = 0.0$ s	$x_0 = 1.00$ m
$t_1 = 1.0$ s	$x_1 = 2.42$ m
$t_2 = 2.0$ s	$x_2 = 4.13$ m
$t_3 = 3.0$ s	$x_3 = 5.52$ m
$t_4 = 4.0$ s	$x_4 = 7.26$ m
$t_5 = 5.0$ s	$x_5 = 8.41$ m
$t_6 = 6.0$ s	$x_6 = 10.00$ m

TIP The quantity that appears on the vertical axis of a graph can represent the position of an object whose actual position is changing along any axis. The position on the vertical axis does not mean the object is moving in the vertical direction.

Correspondence between a motion diagram and position-versus-time graph

To understand how graphs relate to motion diagrams, consider the motion represented by the data in Table 2.2 and in Figure 2.13c. **Figure 2.14** shows a modified motion diagram for the data in Table 2.2 (the dot times are shown and the $\Delta\vec{v}$ arrows have been removed for simplicity) and the corresponding position-versus-time graph. The position of each dot on the motion diagram corresponds to a point on the position axis. The graph line combines the information about the position of an object and the clock reading when this position occurred. Note, for example, that the $t = 4.0$ s dot on the motion diagram at position $x = 7.26$ m is at 7.26 m on the position axis. The corresponding dot on the graph is at the intersection of the vertical line passing through 4.0 s and the horizontal line passing though 7.26 m.

FIGURE 2.14 Correspondence between a motion diagram and the position-versus-time graph.

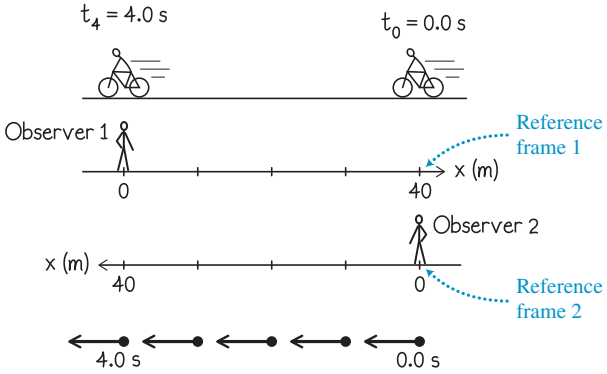
The role of a reference frame

Always keep in mind that representations of motion (motion diagrams, tables, kinematics graphs, equations, etc.) depend on the reference frame chosen. Let's look at the representations of the motion of a cyclist using two different reference frames.

CONCEPTUAL EXERCISE 2.3 Effect of reference frame on motion description

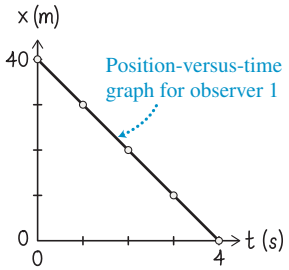
Two observers each use different reference frames to record the changing position of a bicycle rider. Both reference frames use Earth as the object of reference, but the origins of the coordinate systems and the directions of the x-axes are different. The data for the cyclist's trip are presented in **Table 2.3** for observer 1 and in **Table 2.4** for observer 2. Sketch a motion diagram and a position-versus-time graph for the motion when using each reference frame.

TABLE 2.3 Time-position data for cyclist when using reference frame 1

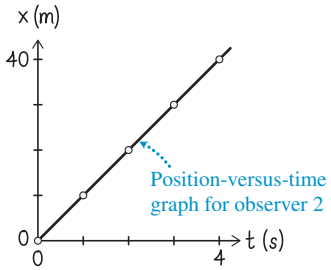


Clock reading (time)	Position
$t_0 = 0.0$ s	$x_0 = 40.0$ m
$t_1 = 1.0$ s	$x_1 = 30.0$ m
$t_2 = 2.0$ s	$x_2 = 20.0$ m
$t_3 = 3.0$ s	$x_3 = 10.0$ m
$t_4 = 4.0$ s	$x_4 = 0.0$ m

TABLE 2.4 Time-position data for cyclist when using reference frame 2



Clock reading (time)	Position
$t_0 = 0.0$ s	$x_0 = 0.0$ m
$t_1 = 1.0$ s	$x_1 = 10.0$ m
$t_2 = 2.0$ s	$x_2 = 20.0$ m
$t_3 = 3.0$ s	$x_3 = 30.0$ m
$t_4 = 4.0$ s	$x_4 = 40.0$ m



(CONTINUED)

Sketch and translate According to Table 2.3, the observer in reference frame 1 sees the cyclist (the object of interest) at time $t_0 = 0.0$ s at position $x_0 = 40.0$ m and at $t_4 = 4.0$ s at position $x_4 = 0.0$ m. Thus, the cyclist is moving in the negative direction relative to the coordinate axis in reference frame 1. Meanwhile, according to Table 2.4, the observer in reference frame 2 sees the cyclist at time $t_0 = 0.0$ s at position $x_0 = 0.0$ m and at time $t_4 = 4.0$ s at position $x_4 = 40.0$ m. Thus, the cyclist is moving in the positive direction relative to reference frame 2.

Simplify and diagram Since the size of the cyclist is small compared to the distance he is traveling, we can represent him as a point-like object. The motion diagram for the cyclist is the same for both observers, as they are using the same object of reference. Using the data in the tables, we plot kinematics position-versus-time graphs for each observer at top right. Although the graph for observer 1 looks very different from the graph for observer 2, they represent the same motion. The graphs look different because the reference frames are different.

Try it yourself A third observer recorded the values (in **Table 2.5**) for the time and position of the same cyclist. Describe the reference frame of this observer.

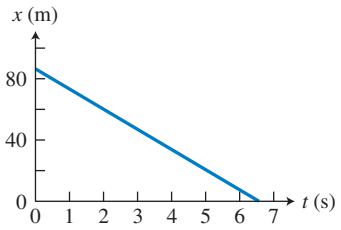
TABLE 2.5 Data collected by the third observer

Clock reading (time)	Position
$t_0 = 0.0$ s	$x_0 = 0.0$ m
$t_1 = 1.0$ s	$x_1 = -20.0$ m
$t_2 = 2.0$ s	$x_2 = -40.0$ m
$t_3 = 3.0$ s	$x_3 = -60.0$ m
$t_4 = 4.0$ s	$x_4 = -80.0$ m

Answer The point of reference could be another cyclist moving in the opposite positive direction from the direction in which the first cyclist is traveling, with each covering the same distance relative to the ground during the same time interval.

REVIEW QUESTION 2.5 A position-versus-time graph representing a moving object is shown in **Figure 2.15**. What are the positions of the object at clock readings 2.6 s and 5.8 s?

FIGURE 2.15 A position-versus-time graph representing a moving object.



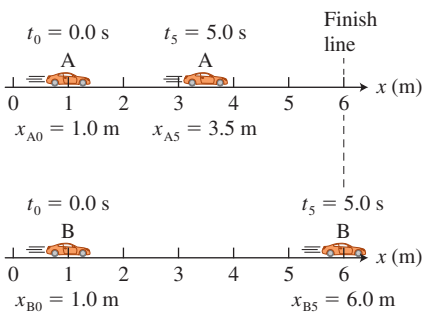


FIGURE 2.16 Positions of cars A and B at 0 s and 5.0 s.

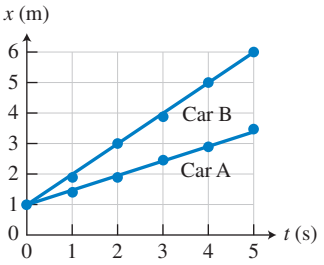
2.6 Constant velocity linear motion

In the last section we devised a graphical representation of motion. Here we will connect graphs to mathematical representations using the example of two motorized toy cars racing toward a finish line. At time 0 they are next to each other, but car B is moving faster than car A and reaches the finish line first (**Figure 2.16**). The data that we collect are shown in Observational Experiment **Table 2.6**. Earth is the object of reference. The origin of the coordinate system (the point of reference) is 1.0 m to the left of the position of the cars at $t_0 = 0$. The positive x-direction points right in the direction of the cars' motions. Now let's use the data to find a pattern.

OBSERVATIONAL EXPERIMENT TABLE 2.6  **Graphing the motion of cars**

Observational experiment

Data for car A



$t_0 = 0.0$ s	$x_0 = 1.0$ m
$t_1 = 1.0$ s	$x_1 = 1.4$ m
$t_2 = 2.0$ s	$x_2 = 1.9$ m
$t_3 = 3.0$ s	$x_3 = 2.5$ m
$t_4 = 4.0$ s	$x_4 = 2.9$ m
$t_5 = 5.0$ s	$x_5 = 3.5$ m

Data for car B

$t_0 = 0.0$ s	$x_0 = 1.0$ m
$t_1 = 1.0$ s	$x_1 = 1.9$ m
$t_2 = 2.0$ s	$x_2 = 3.0$ m
$t_3 = 3.0$ s	$x_3 = 3.9$ m
$t_4 = 4.0$ s	$x_4 = 5.0$ m
$t_5 = 5.0$ s	$x_5 = 6.0$ m

Analysis

We graph the data with the goal of finding a pattern. The trendlines for both cars are straight lines. The line for car B has a bigger angle with the time axis than the line for car A.

Pattern

It looks like a straight line is the simplest reasonable choice for the best-fit curve in both cases (the data points do not have to be exactly on the line).

In Table 2.6, the slope of the line representing the motion of car B is greater than the slope of the line representing the motion of car A. What is the physical meaning of this slope? In mathematics the value of a dependent variable is usually written as y and depends on the value of an independent variable, usually written as x. A function $y(x) = f(x)$ is an operation that one needs to do to x as an input to have y as the output. For a straight line, the function $y(x)$ is $y(x) = mx + b$, where m is the slope and b is the y-intercept—the value of the y when $x = 0$.

In the case of the cars, the independent variable is time t and the dependent variable is position x. The equation of a straight line becomes $x(t) = mt + b$, where b is the x-intercept of the line, and m is the slope of the line. The x-intercept is the x-position when $t = 0$, also called the initial position of the car x_0. Both cars started at the same location: $x_{A0} = x_{B0} = 1.0$ m.

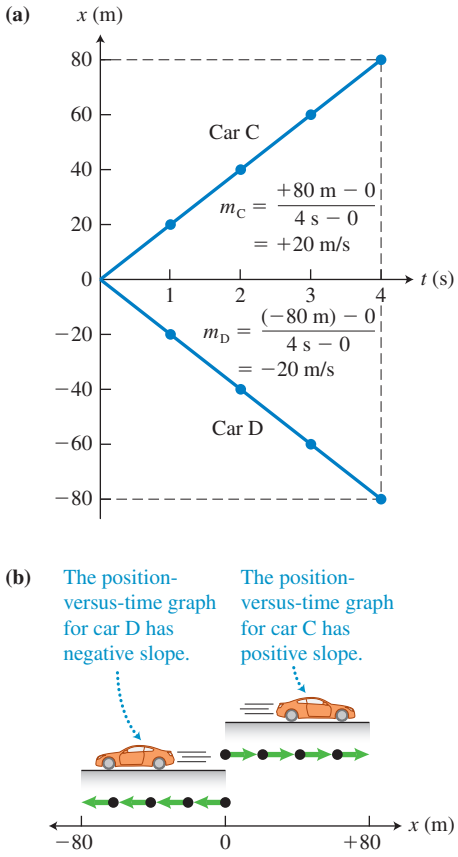
To find the **slope** m of a straight line, we can choose *any* two points on the line and divide the change in the vertical quantity (Δx in this case) by the change in the horizontal quantity (Δt in this case):

$$m = \frac{x_2 - x_1}{t_2 - t_1} = \frac{\Delta x}{\Delta t}$$

For example, for car A the slope of the line is

$$m_A = \frac{3.5\text{ m} - 1.0\text{ m}}{5.0\text{ s} - 0.0\text{ s}} = +0.5\text{ m/s}$$

The slope of the line for car B is



$$m_B = \frac{6.0\text{ m} - 1.0\text{ m}}{5.0\text{ s} - 0.0\text{ s}} = +1.0\text{ m/s}$$

Now we have all the information we need to write mathematical equations that describe the motion of each of the two cars:

$$\text{Car A:} \quad x_A = (+0.5\text{ m/s})t + (1.0\text{ m})$$
$$\text{Car B:} \quad x_B = (+1.0\text{ m/s})t + (1.0\text{ m})$$

Notice that the units of the slope are meters per second. The slope indicates how the object's position changes with respect to time. The slope of the line contains more information than just how fast the car is going. It also tells us the direction of motion relative to the coordinate axis.

FIGURE 2.17 The sign of the slope indicates the direction of motion.

Consider the motions represented graphically in **Figure 2.17a**. The slope of the position-versus-time graph for car C is $+20$ m/s, but the slope of the position-versus-time graph for car D is -20 m/s. What is the significance of the minus sign? Car C is moving in the positive direction, but car D is moving in the negative direction (check the motion diagrams in Figure 2.17b). The magnitudes of the slopes of their position-versus-time graphs are the same, but the signs are different. Thus, in addition to the information about how fast the car is traveling (its **speed**), the slope tells in what direction it is traveling. Together, speed and direction are called **velocity**, and this is what the slope of a position-versus-time graph represents. You are already familiar with the term "velocity arrow" used on motion diagrams. Now you have a formal definition for velocity as a physical quantity.

Velocity and speed for constant velocity linear motion For constant velocity linear motion, the component of velocity v_x along the axis of motion can be found as the slope of the position-versus-time graph or the ratio of the component of the displacement of an object $x_2 - x_1$ during *any* time interval $t_2 - t_1$:

$$v_x = \frac{x_2 - x_1}{t_2 - t_1} = \frac{\Delta x}{\Delta t} \tag{2.1}$$

where the subscript x next to the v symbol indicates the direction of the axis and t_1 and t_2 are the two clock readings when the positions x_1 and x_2 were measured. Examples of units of velocity are m/s, km/h, and mi/h (which is often written as mph). *Speed* is the magnitude of the velocity and is always a positive number.

TIP Equation (2.1) allows you to use *any* change in position divided by the time interval during which that change occurred to obtain the same number—as long as the position-versus-time graph is a straight line (the object is moving at constant velocity). Later in the chapter, you will learn how to modify this equation for cases in which the velocity is not constant.

Note that velocity is a vector quantity. In vector form, motion at constant velocity is $\vec{v} = \vec{d}/\Delta t$, where $\vec{d}$ is the displacement vector and Δt is the time interval. Here we divide a vector by a scalar. You learned this operation in Section 2.3. The velocity vector has the same direction as the displacement vector (direction of motion), but the magnitude is different as well the units. The magnitude of the velocity vector is speed. The displacement vector has units of length (m), and the time interval has units of time (s). Thus the velocity vector has the units of m/s. Since it is difficult to operate mathematically with vectors, we will work with components. When the velocity vector points in the positive direction of the x-axis, the x-component of velocity is equal to the magnitude of the velocity vector. When the velocity vector points in the negative direction of the axis, the x-component of velocity is equal to the magnitude of the velocity vector with the negative sign.

Equation of motion for constant velocity linear motion

We can rearrange Eq. (2.1) into a form that allows us to determine the position of an object at time t_2 knowing only its position at time t_1 and the x-component of its velocity: $x_2 = x_1 + v_x(t_2 - t_1)$. If we apply this equation for time 0 ($t_0 = 0$) when the initial position is x_0, then the position x at any later position time t can be written as follows:

Position equation for constant velocity linear motion

$$x = x_0 + v_x t \tag{2.2}$$

where x is the function $x(t)$, position x_0 is the position of the object at time $t_0 = 0$ with respect to a particular reference frame, and the (constant) x-component of the velocity of the object v_x is the slope of the position-versus-time graph.

Below you see a new type of task—a Quantitative Exercise. Quantitative Exercises include two steps of the problem-solving process: "Represent mathematically" and "Solve and evaluate." Their purpose is to help you practice using new equations right away.

QUANTITATIVE EXERCISE 2.4 A cyclist

In Conceptual Exercise 2.3, you constructed graphs for the motion of a cyclist using two different reference frames. Now construct mathematical representations (equations) for the cyclist's motion for each of the two graphs. Do the equations indicate the same position for the cyclist at time $t = 6.0$ s?

Represent mathematically The cyclist moves at constant velocity; thus the general mathematical description of his motion is $x = x_0 + v_x t$, where

$$v_x = \frac{x_2 - x_1}{t_2 - t_1}$$

Solve and evaluate Using the graph for reference frame 1 in Conceptual Exercise 2.3, we see that the cyclist's initial position is $x_0 = +40$ m. The velocity along the x-axis (the slope of the graph) is

$$v_x = \frac{0\text{ m} - 40\text{ m}}{4\text{ s} - 0\text{ s}} = -10\text{ m/s}$$

The minus sign indicates that the velocity points in the negative x-direction (toward the left) relative to that axis. The motion of the bike with respect to reference frame 1 is described by the equation

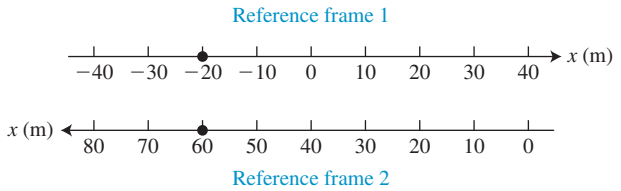
$$x = x_0 + v_x t = 40\text{ m} + (-10\text{ m/s})t$$

Using the graph for reference frame 2, we see that the cyclist's initial position is $x_0 = 0$ m. The x-component of the velocity along the axis of motion is

$$v_x = \frac{40\text{ m} - 0\text{ m}}{4\text{ s} - 0\text{ s}} = +10\text{ m/s}$$

The positive sign indicates that the velocity points in the positive x-direction (toward the left). The motion of the bike relative to reference frame 2 is described by the equation

$$x = x_0 + v_x t = 0\text{ m} + (10\text{ m/s})t$$



The position of the cyclist at time $t_1 = 6$ s with respect to reference frame 1 is

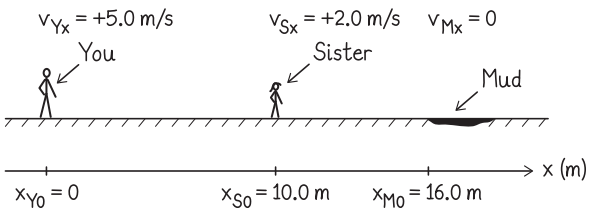
$$x = 40\text{ m} + (-10\text{ m/s})(6\text{ s}) = -20\text{ m}$$

With respect to reference frame 2:

$$x = 0\text{ m} + (+10\text{ m/s})(6\text{ s}) = +60\text{ m}$$

How can the position of the cyclist be both −20 m and +60 m? Remember that the description of motion of an object depends on the reference frame. If you put a dot on coordinate axis 1 at the −20 m position and a dot on coordinate axis 2 at the +60 m position, you find that the dots are in fact at the same location, even though that location corresponds to a different position in each reference frame. Both descriptions of the motion are correct and consistent, but each one is meaningful only with respect to the corresponding reference frame.

Try it yourself Use the data for the motion of the cyclist as seen by the third observer in the "Try it yourself" part of Conceptual Exercise 2.3 to write the equation of motion. Why is the magnitude of the cyclist's velocity different than the 10 m/s in the example above?

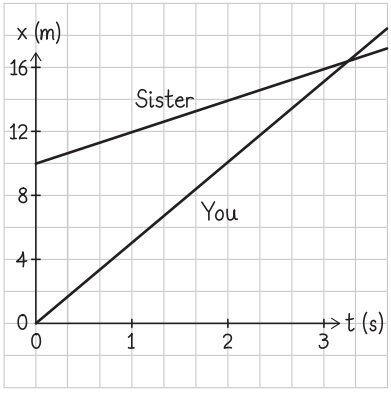


Answer $x = (0\text{ m}) + (-20\text{ m/s})t$. The observer is moving with respect to Earth at the same speed in the direction opposite to the cyclist.

Below you see another new type of task—a worked example. The worked examples include all four steps of the problem-solving strategy we use in this book. (See Chapter 1 for descriptions of these steps.)

EXAMPLE 2.5 You chase your sister

Your young sister is running at 2.0 m/s toward a mud puddle that is 6.0 m in front of her. You are 10.0 m behind her running at 5.0 m/s to catch her before she jumps into the mud. Will she need a bath?



Sketch and translate We start by drawing a sketch of what is happening. Your sister and you are two objects of interest. Next, we choose a reference frame with Earth as the object of reference. The origin of the coordinate system is your initial position and the positive direction is toward the right, in the direction that you both run, as shown at right. Notice the subscripts for the given quantities. The first subscript indicates the object, and the second indicates the time. For example, x_{Y0} means your position at the zero clock reading.

(CONTINUED)

We can now mathematically describe the positions and velocities of you and your sister at the beginning of the process. The initial clock reading is zero at the moment that you are at the origin. Note that you were both running before time zero; this just happened to be the time when we started analyzing the process. We want to know the time when you and your sister are at the same position. This will be the position where you catch up to her.

Simplify and diagram We assume that you and your sister are point-like objects. To sketch graphs of the motions, find your sister's position at 1 s by multiplying her speed by 1 s and adding it to her initial position. Do this for 2 and 3 s as well. Plot these values on a graph for the corresponding clock readings (1 s, 2 s, 3 s, etc.) and draw a line that extends through these points. Repeat this process for yourself.

Represent mathematically Use Eq. (2.2) to construct mathematical representations of motion. The form of the equation is the same for both ($x = x_0 + v_x t$); however, the values for the initial positions and the components of the velocities along the axis for your sister, $x_S = x_{S0} + v_{Sx}t$, and for you, $x_Y = x_{Y0} + v_{Yx}t$, are different. Now we can use the values of the quantities from the sketch.

$$\begin{aligned} \text{Sister:} \quad & x_S = (10.0\ \text{m}) + (2.0\ \text{m/s})t \\ \text{You:} \quad & x_Y = (0.0\ \text{m}) + (5.0\ \text{m/s})t \end{aligned}$$

From the graphs, we see that the distance between you and your sister is shrinking with time. Do the equations tell the same story? For example, at time $t = 2.0$ s, your sister is at position

$$x_S(2\ \text{s}) = (10.0\ \text{m}) + (2.0\ \text{m/s})(2.0\ \text{s}) = 14.0\ \text{m}$$

and you are at

$$x_Y(2\ \text{s}) = (0.0\ \text{m}) + (5.0\ \text{m/s})(2.0\ \text{s}) = 10.0\ \text{m}$$

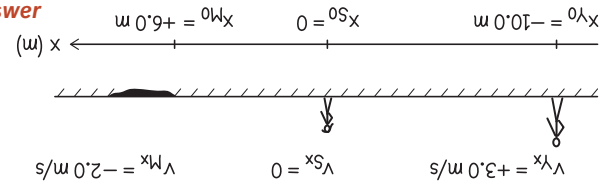
You are catching up to your sister.

Solve and evaluate The time t at which the two of you are at the same position can be found by setting $x_S(t) = x_Y(t)$:

$$(10.0\ \text{m}) + (2.0\ \text{m/s})t = (0.0\ \text{m}) + (5.0\ \text{m/s})t$$

Rearrange the above to determine the time t when you are both at the same position:

$$\begin{aligned} (2.0\ \text{m/s})t - (5.0\ \text{m/s})t &= (0.0\ \text{m}) - (10.0\ \text{m}) \\ (-3.0\ \text{m/s})t &= -(10.0\ \text{m}) \\ t &= 3.33333333\ \text{s} \end{aligned}$$



The 3.33333333 s number produced by our calculator has many more significant digits than the givens. Should we round it to have the same number of significant digits as the given quantities? The rule of thumb is that if it is the final result, you need to round this number to 3.3, as the answer cannot be more precise than the given information. However, we do not round the result of an intermediate calculation. We use the result as is to calculate the next quantity needed to get the final answer and then round the final result.

$$\begin{aligned} \text{Sister:} \quad x_S(t) &= (10.0\ \text{m}) + (2.0\ \text{m/s})(3.33333333\ \text{s}) \\ &= 16.7\ \text{m} \\ \text{You:} \quad x_Y(t) &= (0.0\ \text{m}) + (5.0\ \text{m/s})(3.33333333\ \text{s}) \\ &= 16.7\ \text{m} \end{aligned}$$

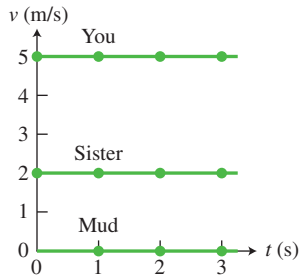
Note that if you used the rounded number 3.3 s, you would get 16.6 m for your sister and 16.5 m for you. These numbers are slightly smaller than the result calculated above. However, for our purposes it does not matter, as the goal of this example was to decide if you could catch your sister before she reaches the puddle. Since you caught her at a position of about 16.7 m, with the uncertainty of about 0.1 m, this position is slightly greater than the 16.0-m distance to the puddle. Therefore, your sister reaches the puddle before you and will indeed need a bath. This answer seems consistent with the graphical representation of the motion shown above. Note that we used the symbol t to denote the specific clock reading when you catch your sister. Often, the same symbol is used to denote both a variable and some specific value. Always ask yourself what a symbol means when you read it.

Try it yourself Describe the problem situation using a reference frame with your sister (not Earth) as the object and point of reference and the positive direction pointing toward the puddle.

Answer

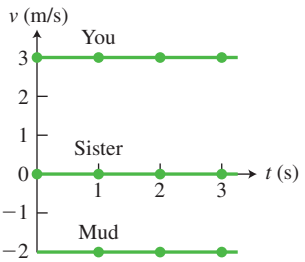
With respect to this reference frame, your sister is at position 0 and at rest; you are initially at -10.0 m and moving toward your sister with velocity $+3.0$ m/s; and the mud puddle is initially at $+6.0$ m and moving toward your sister with velocity -2.0 m/s.

TIP In the reference frame we chose in Example 2.5, the positions of you and your sister are always positive, as are the components of your velocities. Also, your initial position is zero. Thus the calculations are the easiest. Often the description of the motion of object(s) will be simplest in one particular reference frame. There is not one general rule for finding such a frame; however, it is helpful to consider which frame will result in positive values for the most quantities.



Graphing velocity

So far, we have learned to make position-versus-time graphs. We could also construct a graph of an object's velocity as a function of time. Consider Example 2.5, in which you chase your sister. Again we will use Earth as the object of reference. You are moving at a constant velocity whose x-component is $v_x = +5.0\ \text{m/s}$. For your sister, the x-component of velocity is $+2.0\ \text{m/s}$. We place clock readings on the horizontal axis and the x-component of your and your sister's velocities on the vertical axis; then we plot points for these velocities at each time (see **Figure 2.18a**). The best-fit curve for each person is a horizontal straight line, which makes sense since neither velocity is changing. For you, the equation of the best-fit line is $v_{Yx}(t) = +5.0\ \text{m/s}$, and for your sister, it is $v_{Sx}(t) = +2.0\ \text{m/s}$, where $v_x(t)$ represents the x-component of velocity as a function of time.



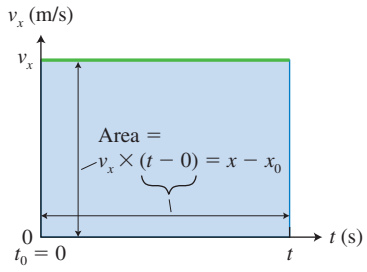
If instead we choose your sister as the object of reference, her velocity with respect to herself is zero, so the best-fit curve is again a horizontal line but at a value of $0.0\ \text{m/s}$ instead of $+2.0\ \text{m/s}$; your velocity is $+3.0\ \text{m/s}$ (see Figure 2.18b); and the mud's velocity is $-2.0\ \text{m/s}$. The minus sign indicates that from your sister's point of view, the mud is moving in the negative direction toward her at speed $+2.0\ \text{m/s}$.

FIGURE 2.18 Velocity-versus-time graphs.

(a) v-versus-t graph lines with Earth as object of reference

(b) v-versus-t graph lines with Sister as object of reference

Finding displacement from a velocity graph



We have just learned to construct a velocity-versus-time graph. Can we get anything more out of such graphs besides being able to represent velocity graphically? As you know, for constant velocity linear motion, the position of an object changes with time according to $x = x_0 + v_x t$. Rearranging this equation a bit, we get $x - x_0 = v_x t$, where t is the time interval during which the motion occurred, assuming that the motion started at zero clock reading ($t_0 = 0$). The left side is the displacement of the object from time zero to time t. Now look at the right side: v_x is the vertical height of the velocity-versus-time graph line and t is the horizontal width from time zero to time t (see **Figure 2.19**). We can interpret the right side as the shaded area between the velocity-versus-time graph line and the time axis. In equation $x - x_0 = v_x t$, this area (the right side) equals the displacement of the object from time zero to time t on the left side of the equation. Here the displacement is a positive number because we chose an example with positive velocity.

Let's extend this reasoning to more general cases: an object initially at position x_1 at time t_1 and later at position x_2 at time t_2 and moving in either the positive or negative direction.

Displacement is the area between a velocity-versus-time graph line and the time axis For motion with constant velocity, the magnitude of the displacement $x_2 - x_1$ (the distance traveled) of an object during a time interval from t_1 to t_2 is the area between a velocity-versus-time graph line and the time axis between those two clock readings. The displacement is the area with a plus sign when the velocity is positive and the area with a negative sign when velocity is negative.

TIP Notice that a horizontal line on a position-versus-time graph means that the object is at rest (the position is constant with time). A horizontal line on a velocity-versus-time graph means that the object is moving at constant velocity (its velocity does not change with time).

FIGURE 2.19 Using the v_x-versus-t graph to determine displacement $x - x_0$.

An object's displacement $x - x_0$ between $t_0 = 0$ and time interval $t - 0$ is the area between the v_x-versus-t curve and the t axis.

QUANTITATIVE EXERCISE 2.6 **Displacement of you and your sister**

Use the velocity-versus-time graphs shown in Figure 2.18a for you and your sister (see Example 2.5) to find your displacements with respect to Earth for the time interval from 0 to 3.0 s. The velocity components relative to Earth are $+2.0\ \text{m/s}$ for your sister and $+5.0\ \text{m/s}$ for you.

Represent mathematically For constant velocity motion, the object's displacement $x - x_0$ is the area of a rectangle whose vertical side equals the object's velocity v_x and whose horizontal side equals the time interval $t - t_0 = t - 0$ during which the motion occurred.

Solve and evaluate The displacement of your sister heading toward the mud puddle during the 3.0-s time interval is the product of her velocity and the time interval:

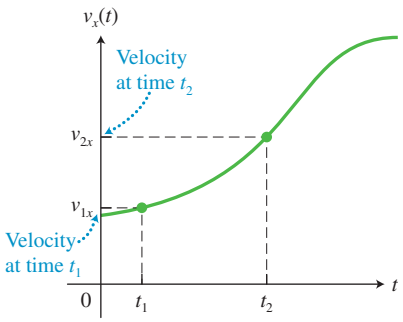
$$d_S = (x - x_0)_S = (+2.0\ \text{m/s})(3.0\ \text{s}) = +6.0\ \text{m}$$

(CONTINUED)

She was originally at position 10.0 m, so she is now at position $(10.0 + 6.0)\ \text{m} = +16.0\ \text{m}$. Your displacement during that same 3.0-s time interval is the product of your velocity and the time interval:

$$d_Y = (x - x_0)_Y = (+5.0\ \text{m/s})(3.0\ \text{s}) = +15.0\ \text{m}$$

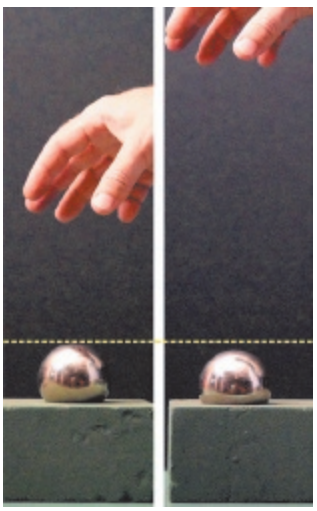
You were originally at 0.0 m, so you are now at +15.0 m, 1.0 m behind your sister.



Try it yourself Determine the magnitudes of the displacements of you and your sister from time 0 to time 2.0 s and your positions at that time. Your initial position is zero and your sister's is 10 m.

Answer

Your sister's values are $d_S = 4.0$ m and $x_S = 14.0$ m, and your values are $d_Y = 10.0$ m and $x_Y = 10.0$ m. She is 4.0 m ahead of you at that time.



REVIEW QUESTION 2.6 Why is the following statement true? "Displacement is equal to the area between a velocity-versus-time graph line and the time axis with a positive or negative sign."

FIGURE 2.20 Velocity-versus-time graph for motion with changing velocity.

TIP Sometimes we use average speed instead of average velocity. To find the average speed divide the total path length by the time of travel. If the object is not changing its direction of motion, the average speed is equal to the magnitude of the average velocity.

FIGURE 2.21 Dropping a metal ball onto a foam block from different heights.

2.7 Motion at constant acceleration

In the last section, the function $v_x(t)$ was a horizontal line on the velocity-versus-time graph because the velocity was constant. How would the graph look if the velocity were changing? One example of such a graph is shown in **Figure 2.20**. A point on the curve indicates the velocity of the object shown on the vertical axis at a particular time shown on the horizontal axis. In this case, the velocity is continually changing and is positive.

Instantaneous velocity and average velocity

The velocity of an object at a particular time is called the **instantaneous velocity**. Figure 2.20 shows a velocity-versus-time graph for motion with continually changing instantaneous velocity. When an object's velocity is changing, we cannot use Eq. (2.1) to determine its instantaneous velocity using any time interval and a corresponding position change, because the ratio

$$v_x = \frac{x_2 - x_1}{t_2 - t_1} = \frac{\Delta x}{\Delta t}$$

is not the same for different time intervals the way it was when the object was moving at constant velocity. We can still use this equation to determine the **average velocity**, which is the ratio of the change in position and the time interval during which this change occurred. For motion at constant velocity, the instantaneous and average velocity are equal; for motion with changing velocity, they are not. However, if the two points chosen are very close together, Δx and Δt are both very small, but the ratio $\Delta x/\Delta t$ is not necessarily large or small. In fact, within a vanishingly small time interval, we can use $\Delta x/\Delta t$ as the definition of the x-component of instantaneous velocity.

When an object moves with changing velocity, its velocity can change quickly or slowly. To characterize the rate at which the velocity of an object is changing, we need a new physical quantity.

Acceleration

Let's start with a simple experiment. We take a metal ball and drop it onto a foam block that deforms when touched. The photos in **Figure 2.21** show that the dent in the block becomes deeper when the ball is dropped from a larger height. Can this result be due to a change in the velocity of the ball as it is falling? That is, does a longer fall mean a

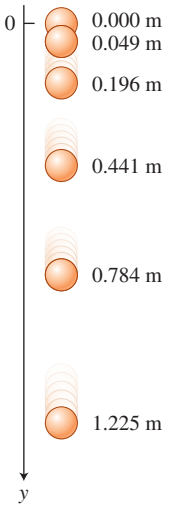
greater velocity and thus a bigger dent? We need to collect data to answer this question. The first two rows of **Table 2.7** show position and time data for the falling ball:

TABLE 2.7 Position and time data for a falling ball

t (s)	0.000	0.100	0.200	0.300	0.400	0.500
y (m)	0.000	0.049	0.196	0.441	0.784	1.225
t^* (s)	0.050	0.150	0.250	0.350	0.450	
v_{av} (m/s)	0.49	1.47	2.45	3.43	4.41	

From the table you can see that the distance that the ball travels during each successive time interval increases; **Figure 2.22** shows the position of the ball every 0.100 s. If the distance that the ball travels during each successive interval increases, the velocity must increase, too. To determine the average velocity during each time interval, we calculate the displacement of the ball between consecutive times and then divide by the time interval. For example, the average velocity between 0.100 s and 0.200 s is $(0.196\ \text{m} - 0.049\ \text{m})/(0.200\ \text{s} - 0.100\ \text{s}) = 1.47\ \text{m/s}$; it is positive because we pointed the axis down. We can think of this average velocity as the instantaneous velocity that the ball had in the middle of the time interval—in this case, the 0.150 clock reading. We can now put these calculated velocities v_{av} and the associated clock readings t^* in the middle of each time interval in the two bottom rows of the table. These data now allow us to plot a velocity-versus-time graph (**Figure 2.23**). Notice that the best-fit curve for these data is a straight line. This occurs when the *velocity of the object increases or decreases at a constant rate*, that is, by the same amount during the same time interval. In our case, the velocity increases by 9.8 m/s every second in the downward direction.

FIGURE 2.22 The position of a falling ball every 0.100 s.



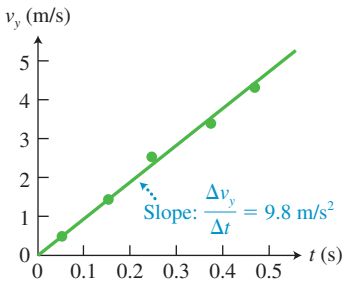


FIGURE 2.23 A velocity-versus-time graph for a falling ball.

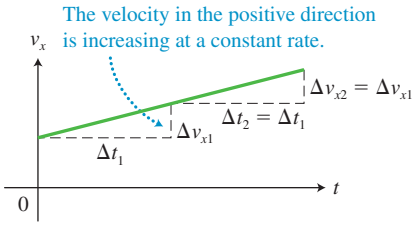
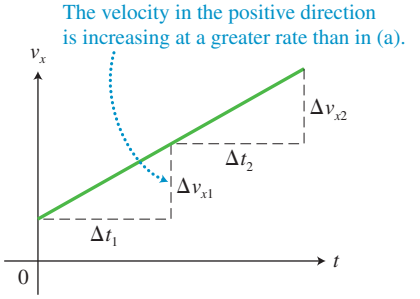
The physical quantity that characterizes how fast instantaneous velocity is changing is equal to the slope of the velocity-versus-time graph and is called **acceleration** $\vec{a}$. The vector symbol above this quantity indicates that it has direction, communicated by the sign of the slope of the velocity-versus-time graph for one-dimensional motion. Similar to velocity, the acceleration of an object moving in a straight line along an x-coordinate axis is defined as

$$a_x = \frac{v_{2x} - v_{1x}}{t_2 - t_1} = \frac{\Delta v_x}{\Delta t}$$



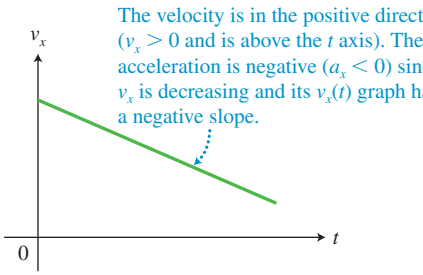
We see that the units of acceleration based on the definition of acceleration are $\frac{\text{m/s}}{\text{s}} = \frac{\text{m}}{\text{s} \cdot \text{s}} = \frac{\text{m}}{\text{s}^2}$.

In the case of a small falling ball, we found that its acceleration is about 9.8 m/s^2, which means that its velocity increases by 9.8 m/s every second.

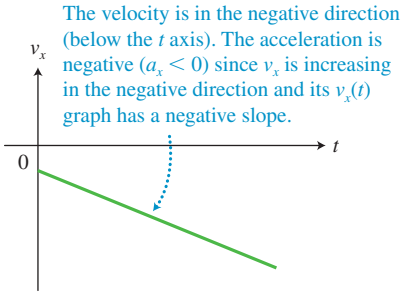


To better understand acceleration, think of a cyclist and a car riding along a road at increasing speeds (**Figures 2.24a** and **b**, on the next page). The accelerations of both objects are constant (as seen from the analysis of the slopes of their velocity-versus-time graphs) but not the same; the car has a greater acceleration. If the car were slowing down,

FIGURE 2.24 Velocity-versus-time graph when the velocity is changing at a constant rate.



(a) A moving cyclist



(b) A moving car

(c) A car slowing down

(d) A car speeding up

its velocity-versus-time graph would instead have a negative slope, which corresponds to a decreasing speed and a negative acceleration, as v_{2x} is smaller than v_{1x} (Figure 2.24c). However, it is not necessary for an object moving with negative acceleration to be slowing down. Examine Figure 2.24d. The car has a negative acceleration and it is speeding up! This happens when the object is moving in the negative direction and has a negative component of velocity, but its speed in the negative direction is increasing in magnitude.

Because velocity is a vector quantity and the acceleration shows how quickly the velocity changes as time progresses, acceleration is also a vector quantity. We can define acceleration in a more general way. The **average acceleration** of an object during a time interval is the following:

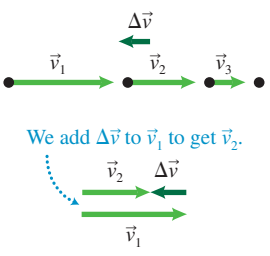
$$\vec{a} = \frac{\vec{v}_2 - \vec{v}_1}{t_2 - t_1} = \frac{\Delta \vec{v}}{\Delta t}$$

To determine the acceleration, we need to determine the velocity change vector $\Delta \vec{v} = \vec{v}_2 - \vec{v}_1$. This equation involves the subtraction of vectors, but you can think of it in terms of addition by rearranging it to be $\vec{v}_1 + \Delta \vec{v} = \vec{v}_2$. Note that $\Delta \vec{v}$ is the vector that we add to $\vec{v}_1$ to get $\vec{v}_2$ (**Figure 2.25**). We did this when making motion diagrams in Section 2.3, only then we were not concerned with the exact lengths of the vectors. The acceleration vector $\vec{a} = \Delta \vec{v}/\Delta t$ is in the same direction as the velocity change vector $\Delta \vec{v}$, as the time interval Δt is a scalar quantity. The units of the acceleration vector are determined by dividing the units of the velocity change vector by the units of time.

Acceleration An object's average acceleration during a time interval Δt is the change in its velocity $\Delta \vec{v}$ divided by that time interval:

$$\vec{a} = \frac{\vec{v}_2 - \vec{v}_1}{t_2 - t_1} = \frac{\Delta \vec{v}}{\Delta t} \qquad (2.3)$$

If Δt is very small, then the acceleration given by this equation is the **instantaneous acceleration** of the object. For one-dimensional motion, the component of the average acceleration along a particular axis (for example, for the x-axis) is



$$a_x = \frac{v_{2x} - v_{1x}}{t_2 - t_1} = \frac{\Delta v_x}{\Delta t} \qquad (2.4)$$

The units of acceleration are $(\text{m/s})/\text{s} = \text{m/s}^2$.

Note that if an object has an acceleration of $+6\ \text{m/s}^2$, it means that its velocity changes by $+6$ m/s in 1 s, or by $+12$ m/s in 2 s $[(+12\ \text{m/s})/(2\ \text{s}) = +6\ \text{m/s}^2]$.

It is possible for an object to have a zero velocity and nonzero acceleration—for example, at the moment when an object starts moving from rest. An object can also have a nonzero velocity and zero acceleration—for example, an object moving at constant velocity. Note that the acceleration of an object depends on the observer. For example, a car is accelerating for an observer on the ground but is not accelerating for the driver of that car.

FIGURE 2.25 How to determine the change in velocity $\Delta \vec{v}$.

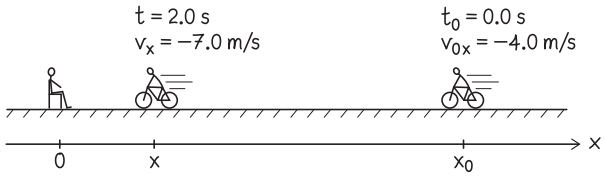
TIP If it is difficult for you to think about velocity and acceleration in abstract terms, try calculating the acceleration for simple integer velocities.

Determining velocity change from acceleration

If, at $t_0 = 0$ for linear motion, the x-component of the velocity of some object is v_{0x} and its acceleration a_x is constant, then its velocity v_x at a later time t can be determined by substituting these quantities into Eq. (2.4):

$$a_x = \frac{v_x - v_{0x}}{t - 0}$$

Rearranging, we get an expression for the changing instantaneous velocity of the object as a function of time:



$$v_x = v_{0x} + a_x t \tag{2.5}$$

Here the value of the velocity at any clock reading is the instantaneous velocity. For one-dimensional motion, the directions of the vector components a_x, v_x, and v_{0x} are indicated by their signs relative to the axis of motion—positive if in the positive x-direction and negative if in the negative x-direction.

EXAMPLE 2.7 **Bicycle ride**

Suppose that you are sitting on a bench watching someone riding a bicycle on a flat, straight road. In a 2.0-s time interval, the velocity of the bicycle changes from −4.0 m/s to −7.0 m/s. Describe the motion of the bicycle as fully as possible.

Sketch and translate We can sketch the process as shown below. The bicycle (the object of interest) is moving in the negative direction with respect to the chosen reference frame. The components of the bicycle's velocity along the axis of motion are negative: $v_{0x} = -4.0$ m/s at time $t_0 = 0.0$ s and $v_x = -7.0$ m/s at $t = 2.0$ s. The speed of the bicycle (the magnitude of its velocity) increases. It is moving faster in the negative direction. We can determine the acceleration of the bicycle and describe the changes in its velocity.

Simplify and diagram Our sketch of the motion diagram for the bicycle is shown below. Note that $\Delta\vec{v}$ points in the negative x-direction.

Represent mathematically We apply Eq. (2.4) to determine the acceleration:

$$a_x = \frac{v_x - v_{0x}}{t - t_0}$$

Solve and evaluate Substituting the given velocities and times, we get

$$a_x = \frac{(-7.0\,\text{m/s}) - (-4.0\,\text{m/s})}{2.0\,\text{s} - 0.0\,\text{s}} = -1.5\,\text{m/s}^2$$

The bicycle's x-component of velocity at time 0 was −4.0 m/s. Its velocity was changing by −1.5 m/s each second. So 1 s later, its velocity was

$$v_{1s\,x} = v_{0x} + \Delta v_x$$
$$= (-4.0\,\text{m/s}) + (-1.5\,\text{m/s}) = -5.5\,\text{m/s}$$

During the second 1-s time interval, the velocity changed by another −1.5 m/s and was then (−5.5 m/s) + (−1.5 m/s) = (−7.0 m/s). In this example, the bicycle was speeding up by 1.5 m/s each second in the negative direction.

Try it yourself A car's acceleration is $-3.0\,\text{m/s}^2$. At time 0 its velocity is +14 m/s. What happens to the velocity of the car? What is its velocity after 3 s?

Answer

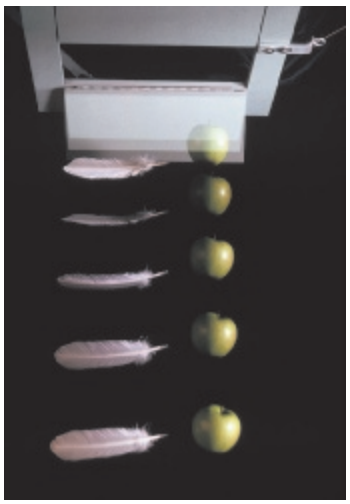
The car's velocity in the positive x-direction is decreasing. After 3 s, $v_x = 5.0$ m/s.

TIP It is possible for an object to have a positive acceleration and be slowing down as well as to have a negative acceleration and be speeding up. When an object is speeding up, the acceleration vector is in the same direction as the velocity vector, and the velocity and acceleration components along the same axis have the same sign. When an object is slowing down, the acceleration is in the opposite direction relative to the velocity; their components have opposite signs.

Free fall

Let's return to the example that led us to the "discovery" of acceleration: dropping a metal ball onto a foam block (Figure 2.21). Galileo Galilei (1564–1642) did experiments similar to ours in which he dropped objects from different heights and examined the resulting dents in sand. However, he also noticed that objects of different shapes fall differently—for example, a piece of paper falls more slowly than a heavy brick. He hypothesized that this difference was due to air resistance. *If* his hypothesis were correct, *then* in a vacuum (space devoid of air), all objects would fall with the same acceleration. Indeed, in a large vacuum chamber, when a light feather and a heavy apple fall, they are always next to each other, meaning that they have the same velocity and acceleration at every instant (**Figure 2.26**). You can perform this testing experiment,

FIGURE 2.26 A feather and an apple fall side by side in a vacuum.



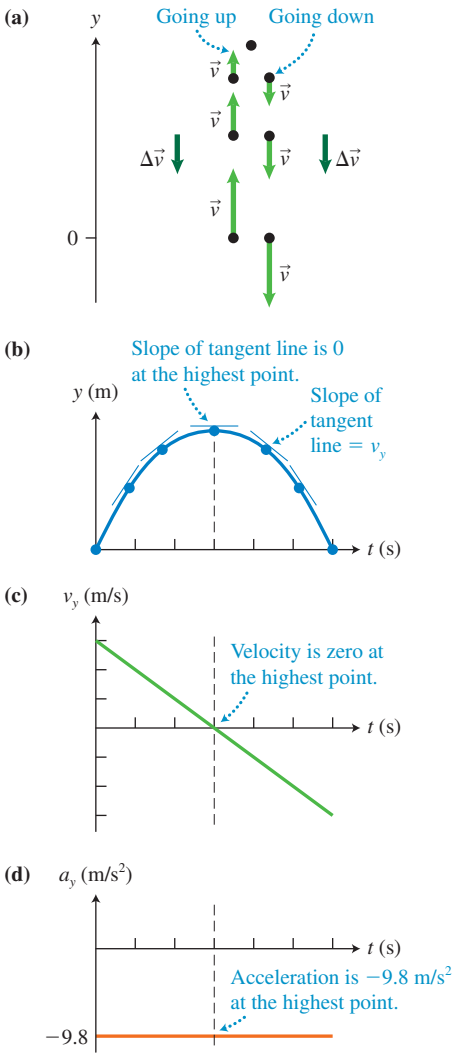


FIGURE 2.27 Motion for an upward thrown ball.

too: take a heavy ball and a tennis ball, drop them at the same time from a height of about 2 m, and videotape the process. You will see them moving side by side!

Earlier in this section we found that the acceleration of the falling metal ball was about 9.8 m/s^2. At the same location, without air resistance, all falling objects will have this same acceleration; however, at another location on Earth, the value of acceleration might be slightly different. We will learn why in Chapter 5.

If we videotape a small object thrown upward and then use the data to construct a velocity-versus-time graph, we find that its acceleration is still the same at all clock readings. For an upward-pointing axis, the object's acceleration is −9.8 m/s^2 on the way up, −9.8 m/s^2 on the way down, and even −9.8 m/s^2 at the instant when the object is momentarily at rest at the highest point of its motion. At all times during the object's flight, its velocity is changing at a rate of −9.8 m/s each second. A motion diagram and the graphs representing the position-versus-time, velocity-versus-time, and acceleration-versus-time are shown in **Figure 2.27**. The positive direction is up. Notice that when the object is at its maximum height on the position-versus-time graph, the velocity is instantaneously zero (the slope of the position-versus-time graph is zero). The acceleration is never zero, even at the moment when the velocity of the object is zero.

It might be tempting to think that at the instant an object is not moving, its acceleration must be zero. This is only true for an object that is at rest and remains at rest. In the case of an object thrown upward, if its acceleration at the top of the flight is zero, it would never descend (it would remain at rest at its highest point).

The motion described above is called a **free fall**. Free fall is an example of a simplified model of motion in which we assume that there is no air or any other medium affecting the motion of a dropped or thrown (upward or downward) object. All objects in free fall have the same acceleration. We will learn the explanation for this phenomenon in Chapter 3. Note that physicists use the term free fall even when the object is moving up.

REVIEW QUESTION 2.7 (a) Give an example in which an object with negative acceleration is speeding up. (b) Give an example in which an object with positive acceleration is slowing down. (c) Give an example in which an object with zero velocity is accelerating.

2.8 Displacement of an object moving at constant acceleration

Equation (2.2) allows us to predict the location of an object moving at constant velocity at any time if we know its velocity and initial position. Can we construct a similar equation for an object moving at constant acceleration? Suppose that at time zero an object is passing the mark x_0 on the axis of motion traveling at velocity v_0 and acceleration a_x. Where will the object be after the time interval $t - 0 = t$? To answer this question, we can use the concept of average velocity. If we know the object's average velocity and initial position, and we assume that the object is moving at this velocity during the time interval of interest, we can predict the position at any time using Eq. (2.2), $x = x_0 + v_{\text{av}\,x}t$.

The average velocity is

$$v_{\text{av}\,x} = \frac{v_x + v_{0x}}{2}$$

where, according to Eq. (2.5), instantaneous velocity is $v_x = v_{0x} + a_x t$. Thus we can write

$$v_{\text{av}\,x} = \frac{v_x + v_{0x}}{2} = \frac{v_{0x} + a_x t + v_{0x}}{2} = \frac{2v_{0x} + a_x t}{2}$$

Therefore, the position of the accelerating object at any time is

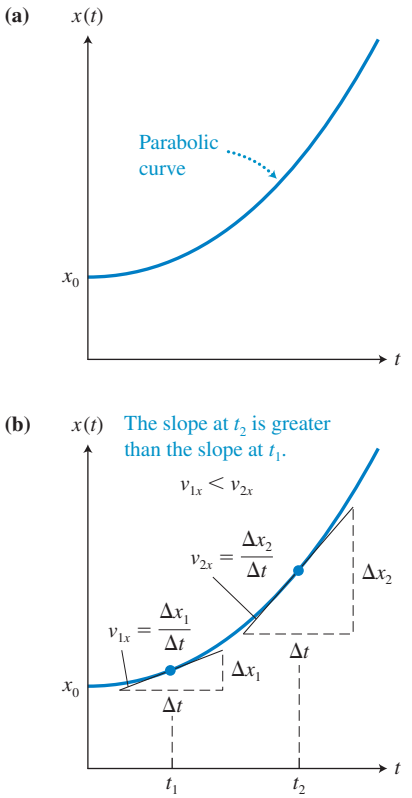
$$x = x_0 + v_{\text{av}x}t = x_0 + \left(\frac{2v_{0x} + a_x t}{2}\right)t$$

$$\Rightarrow x = x_0 + v_{0x}t + \tfrac{1}{2}a_x t^2$$

(The symbol $\Rightarrow$ means that this equation follows from the previous equation.)

Does the above result make sense? Consider a limiting case, for example, when the object is traveling at a constant velocity (when $a_x = 0$). In this case the equation should reduce to the result from our investigation of linear motion with constant velocity ($x = x_0 + v_{x0}t$). It does. We can also check the units of each term in this equation for consistency (when terms in an equation are added or subtracted, each of those terms must have the same units). Each term has units of meters, so the units also check.

Position of an object during linear motion with constant acceleration For any initial position x_0 at clock reading $t_0 = 0$, we can determine the position x of an object at any later time t, provided we also know the initial velocity v_{0x} of the object and its constant acceleration a_x:



$$x = x_0 + v_{0x}t + \tfrac{1}{2}a_x t^2 \qquad (2.6)$$

Since t^2 appears in Eq. (2.6), the position-versus-time graph for this motion is not a straight line but a parabola (a parabola is a graph for a quadratic function) (**Figure 2.28a**). Unlike the position-versus-time graph for constant velocity motion where $\Delta x/\Delta t$ is the same for any time interval, the position-versus-time graph for accelerated motion is not a straight line; it does not have a constant slope. At different times, the change in position Δx has a different value for the same time interval Δt (Figure 2.28b). The line tangent to the position-versus-time graph at a particular time has a slope $\Delta x/\Delta t$ that equals the velocity v_x of the object at that time. The slopes of the tangent lines at different times for the graph in Figure 2.28b differ—they are greater when the position changes more during the same time interval.

The next example involves vertical motion. Thus, we will use a vertical y-coordinate axis and apply the equations of motion.

TIP You can only add or subtract physical quantities that have the same units. The result has the same units as those two quantities. When you multiply or divide quantities, you make a new physical quantity whose units are the result of multiplication or division of the original quantities.

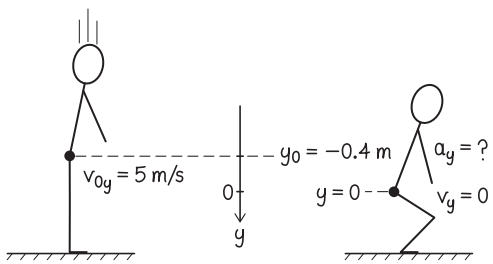


FIGURE 2.28 (a) A position-versus-time graph for constant acceleration motion. (b) The instantaneous velocity v_x is the slope of the position-versus-time graph at a particular clock reading.

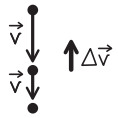
EXAMPLE 2.8 Estimating acceleration of a falling person



A woman jumps off a large boulder. She is moving at a speed of about 5 m/s when she reaches the ground. *Estimate* her acceleration during landing. Indicate any other quantities you use in the estimate.

Sketch and translate To solve the problem, we assume that the woman's knees bend while landing so that her body travels 0.4 m closer to the ground compared to the standing upright position. That is, 0.4 m is the stopping distance for the main part of her body. At right we have sketched the initial and final situations during the landing. We choose the central part of her body as the object of interest. We use a vertical reference with a y-axis pointing down and the final location of the central part of her body as the origin of the coordinate axis. The initial values of her motion at the time $t_0 = 0$ when she first touches the ground are $y_0 = -0.4$ m (the central part of her body is 0.4 m in the negative direction above her final position) and $v_{0y} = +5$ m/s (she is moving downward, the positive direction relative to the y-axis). The final values at some unknown time t at the instant she stops are $y = 0$ and $v_y = 0$. Note: It is important to have a coordinate axis and the initial and final values with appropriate signs.

(CONTINUED)

Simplify and diagram The motion diagram at right represents her motion while stopping, assuming constant acceleration. We cannot model the woman as a point-like object in this situation, so we focus on the motion of her midsection.

Represent mathematically The challenge in representing this situation mathematically is that there are two unknowns: the magnitude of her acceleration a_y (the unknown we wish to determine) and the time interval t between when she first contacts the ground and when she comes to rest. However, both Eqs. (2.5) and (2.6) describe linear motion with constant acceleration and have a_y and t in them. Since we have two equations and two unknowns, we can handle this challenge by solving Eq. (2.5) for the time t

$$t = \frac{v_y - v_{0y}}{a_y}$$

and substitute it into rearranged Eq. (2.6):

$$y = y_0 + v_{0y}t + \tfrac{1}{2}a_y t^2$$

The result is:

$$y - y_0 = v_{0y}\left(\frac{v_y - v_{0y}}{a_y}\right) + \frac{a_y(v_y - v_{0y})^2}{2a_y^2}$$

Using algebra, we can simplify the above equation:

$$\begin{aligned}
\Rightarrow 2a_y(y - y_0) &= 2v_{0y}(v_y - v_{0y}) + (v_y - v_{0y})^2 \\
\Rightarrow 2a_y(y - y_0) &= (2v_{0y}v_y - 2v_{0y}^2) \\
&\quad +(v_y^2 - 2v_y v_{0y} + v_{0y}^2) \\
\Rightarrow 2a_y(y - y_0) &= v_y^2 - v_{0y}^2 \\
\Rightarrow a_y &= \frac{v_y^2 - v_{0y}^2}{2(y - y_0)}
\end{aligned}$$

Solve and evaluate Now we can use the previous equation to find her acceleration:

$$\begin{aligned}
a_y &= \frac{v_y^2 - v_{0y}^2}{2(y - y_0)} \\
&= \frac{(0)^2 - (5\ \text{m/s})^2}{2[\,0 - (-0.4\ \text{m})\,]} = -31\ \text{m/s}^2 \approx -30\ \text{m/s}^2
\end{aligned}$$

Is the answer reasonable? The sign is negative. This means that the acceleration points upward, as does the velocity change arrow in the motion diagram. This is correct. The units for acceleration are correct. We cannot judge yet if the magnitude is reasonable. We will learn later that it is. The answer has one significant digit, as it should—the same as the information given in the problem statement.

Try it yourself Using the expression

$$a_y = \frac{v_y^2 - v_{0y}^2}{2(y - y_0)}$$

decide how the acceleration would change if (a) the stopping distance doubles and (b) the initial speed doubles. Note that the final velocity is $v_y = 0$.

Answer

(a) a_y would be half the magnitude; (b) a_y would be four times the magnitude.

In the "Represent mathematically" step above, we developed a new mathematical relation that is useful when you do not know the time of travel. You do not need to memorize it, but it can come in handy when you solve problems.

A useful equation for linear motion with constant acceleration for situations in which you do not know the time interval during which the changes in position and velocity occurred:

$$2a_x(x - x_0) = v_x^2 - v_{0x}^2 \qquad (2.7)$$

Figure 2.29 shows a different way to derive Eq. (2.6): using the velocity-versus-time graph. Examine the four parts of the figure carefully. You can use the idea of the displacement as the area between the constant velocity graph and the time axis as the starting point for this derivation (Figure 2.29a). Breaking the time axis into small intervals allows us to consider the velocity for those time intervals as constant and to apply the method we used in Figure 2.19 (Figure 2.29b). The result is that the displacement is the area of a trapezium (Figure 2.29c), which can be broken up into two easy-to-calculate areas (Figure 2.29d).

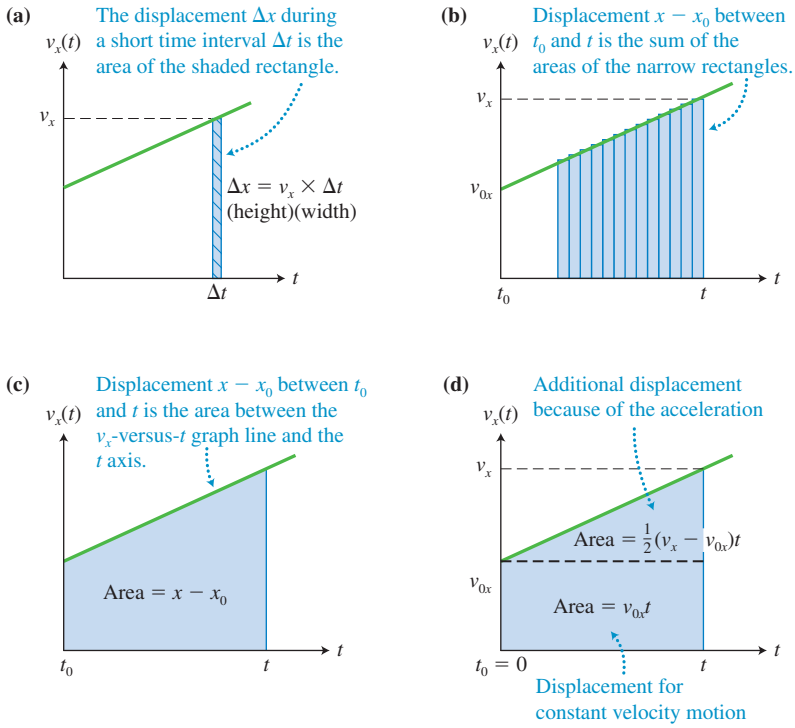


FIGURE 2.29 How to determine the displacement of an object moving at constant acceleration using its velocity-versus-time graph.

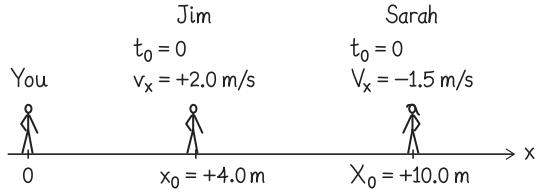
REVIEW QUESTION 2.8 Explain qualitatively, without algebra, why the displacement of an object moving at constant acceleration is proportional to time squared, not to time to the power of 1 as it is for motion at constant velocity.

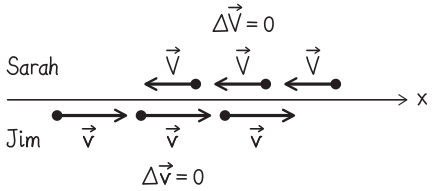
2.9 Skills for analyzing situations involving motion



To help analyze physical processes involving motion, we will represent processes in multiple ways: the words in the problem statement, a sketch, one or more diagrams, possibly a graph, and a mathematical description. Different representations have to agree with each other; in other words, they need to be consistent.

Motion at constant velocity

EXAMPLE 2.9 **Two walking friends**



You stand on a sidewalk and observe two friends walking at constant velocity. At time 0 Jim is 4.0 m east of you and walking away from you at speed 2.0 m/s. Also at time 0, Sarah is 10.0 m east of you and walking toward you at speed 1.5 m/s. Represent their motions with an initial sketch, with motion diagrams, and mathematically.

Sketch and translate We choose Earth as the object of reference with your position as the reference point. The positive direction points to the east. We have two objects of interest here: Jim and Sarah. Jim's initial position is $x_0 = +4.0$ m and his constant velocity is $v_x = +2.0$ m/s. Sarah's initial position is $X_0 = +10.0$ m and her constant velocity is $V_x = -1.5$ m/s (the velocity is negative since she is moving westward). In our sketch we are using capital letters to represent Sarah and lowercase letters to represent Jim.

(CONTINUED)

Simplify and diagram We can model both friends as point-like objects since the distances they move are somewhat greater than their own sizes. The motion diagrams below represent their motions.

Represent mathematically Now construct equations to represent Jim's and Sarah's motion:

Jim: $x = +4.0\text{ m} + (2.0\text{ m/s})t$

Sarah: $X = +10.0\text{ m} + (-1.5\text{ m/s})t$

Solve and evaluate We were not asked to solve for any quantity. We will do it in the "Try it yourself" exercise.

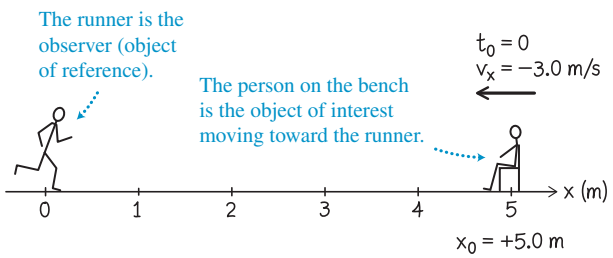
Try it yourself Determine the time when Jim and Sarah are at the same position, and where that position is.

Answer

They are at the same position when $t = 1.7$ s and when $x = X = 7.4$ m.

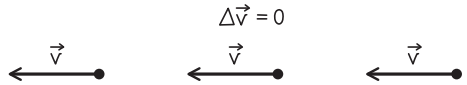
Equation Jeopardy problems

Learning to read the mathematical language of physics with understanding is an important skill. To help develop this skill, this text includes Jeopardy-style problems. In this type of problem, you have to work backwards: you are given one or more equations and are asked to use them to construct a consistent sketch of a process. You then convert the sketch into a diagram of a process that is consistent with the equations and sketch. Finally, you invent a word problem that the equations could be used to solve. Note that there are often many possible word problems for a particular mathematical description.



CONCEPTUAL EXERCISE 2.10 Equation Jeopardy

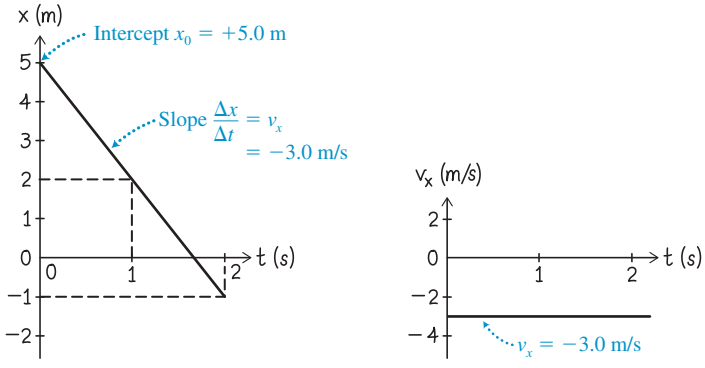
The following equation describes an object's motion:



$$x = (5.0\text{ m}) + (-3.0\text{ m/s})t$$

Construct a sketch, a motion diagram, kinematics graphs, and a verbal description of a situation that is consistent with this equation. There are many possible situations that the equation describes equally well.

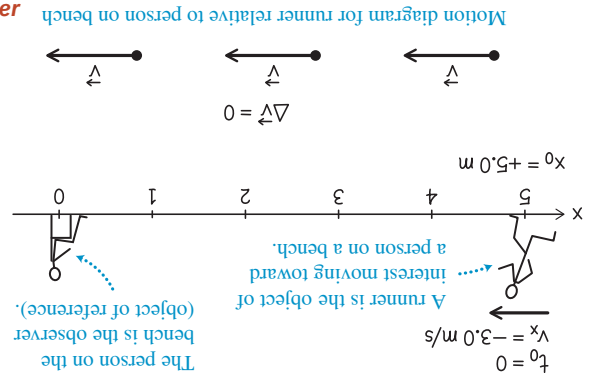
Sketch and translate This equation looks like a specific example of our general equation for the linear motion of an object with constant velocity: $x = x_0 + v_x t$. The minus sign in front of the 3.0 m/s indicates that the object is moving in the negative x-direction. At time 0, the object is located at position $x_0 = +5.0$ m with respect to some chosen object of reference and *is already moving*. Let's imagine that this chosen object of reference is a running person (the observer) and the equation represents the motion of a person (the object of interest) sitting on a bench as seen by the runner. The sketch below illustrates this possible scenario. The positive axis points from the observer (the runner) toward the person on the bench, and at time 0 the person sitting on it is 5.0 m in front of the runner and coming closer to the runner as time elapses.



Simplify and diagram Model the object of interest as a point-like object. A motion diagram for the situation is shown below. The equal spacing of the dots and the equal lengths of velocity arrows both indicate that the object of interest is moving at constant velocity with respect to the observer.

Motion diagram for bench relative to runner

Position-versus-time and velocity-versus-time kinematics graphs of the process are shown below. The position-versus-time graph has a constant -3.0 m/s slope and a $+5.0$ m intercept with the vertical (position) axis. The velocity-versus-time graph has a constant value (-3.0 m/s) and a zero slope (the velocity is not changing). The following verbal description describes this particular process: A jogger sees a person on



a bench in the park 5.0 m in front of him. The bench is approaching at a speed of 3.0 m/s as seen in the jogger's reference frame. The direction pointing from the jogger to the bench is positive.

Try it yourself Suppose we switch the roles of observer and object of reference. Now the person on the bench is the object of reference and observes the runner. We choose to describe the process by the same equation as in the example:

$$x = (5.0\ \text{m}) + (-3.0\ \text{m/s})t$$

Construct an initial sketch and a motion diagram that are consistent with the equation and with the new observer and new object of reference.

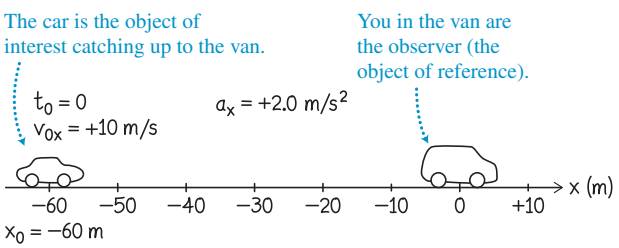
Answer An initial sketch for this process and a consistent motion diagram are shown below.

Motion at constant nonzero acceleration

Now let's apply some representation techniques to linear motion with constant (nonzero) acceleration.

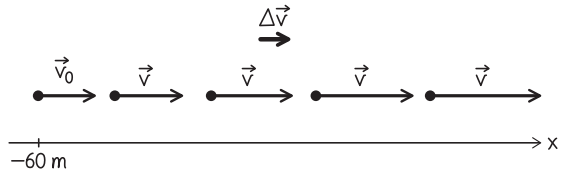
EXAMPLE 2.11 **Equation Jeopardy**

A process is represented mathematically by the following equation:



$$x = (-60\ \text{m}) + (10\ \text{m/s})t + (1.0\ \text{m/s}^2)t^2$$

Use the equation to construct an initial sketch, a motion diagram, and a verbal description of a process that is consistent with this equation.



Sketch and translate The above equation appears to be an application of Eq. (2.6), which we constructed to describe linear motion with constant acceleration, if we assume that the 1.0 m/s^2 in front of t^2 is the result of dividing 2.0 m/s^2 by 2:

$$\begin{aligned} x &= x_0 + v_{0x}t + \tfrac{1}{2}a_x t^2 \\ &= (-60\ \text{m}) + (10\ \text{m/s})t + \tfrac{1}{2}(2.0\ \text{m/s}^2)t^2 \end{aligned}$$

It looks like the initial position of the object of interest is $x_0 = -60$ m, its initial velocity is $v_{0x} = +10$ m/s, and its acceleration is $a_x = +2.0$ m/s^2. Let's imagine that this equation describes the motion of a car on a straight highway passing a van in which you, the observer, are riding. The car is 60 m behind you and moving 10 m/s faster than your van. The car speeds up at a rate of 2.0 m/s^2 with respect to the van. The object of reference is you in the van; the positive direction is the direction in which the car and van are moving. A sketch of the situation follows.

Simplify and diagram The car can be considered a point-like object—much smaller than the dimensions of the path it travels. The car's velocity and acceleration are both positive. Thus, the car's velocity in the positive x-direction is increasing as it moves toward the van (toward the origin). Below is a motion diagram for the car's motion as seen from the van. The successive dots in the diagram are spaced increasingly farther apart as the velocity increases; the velocity arrows are drawn increasingly longer. The velocity change arrow (and the acceleration) point in the positive x-direction, that is, in same direction as the velocity arrows.

Represent mathematically The mathematical representation of the situation appears at the start of the Equation Jeopardy example.

Solve and evaluate To evaluate what we have done, we can check the consistency (agreement) of the different representations. For example, we can check whether the initial position and velocity in the equation, the sketch, and the motion diagram are consistent. In this case, they are.

Try it yourself Describe a different scenario for the same mathematical representation.

Answer This mathematical representation could also describe the motion of a cyclist moving on a straight path as seen by a person standing on a sidewalk 60 m in front of the cyclist. The positive direction is in the direction the cyclist is traveling. When the person starts observing the cyclist, she is moving at an initial velocity of $v_{0x} = +10$ m/s and speeding up with acceleration $a_x = +2.0$ m/s^2.

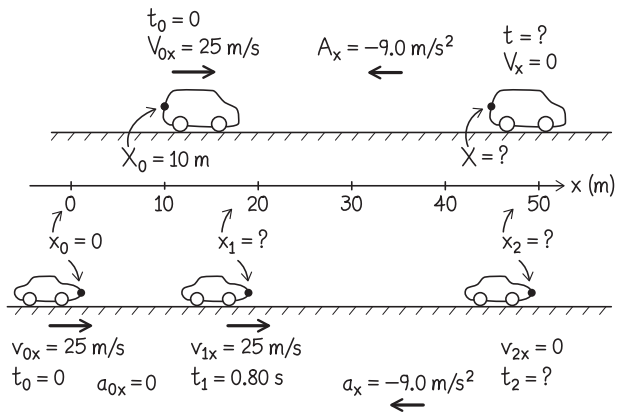
The problem-solving strategy in this text uses multiple representations, an approach that was found to be extremely useful in helping solve physics problems. The complete problem-solving strategy for a particular type of problem will be presented along with an example at the side. Below, the problem-solving steps for kinematics (motion) problems are presented on the left side and illustrated on the right side. The content of this example is also very important: it shows why it is necessary to remain a safe distance behind the car in front of you when driving.

PROBLEM-SOLVING STRATEGY 2.1 Kinematics

Sketch and translate

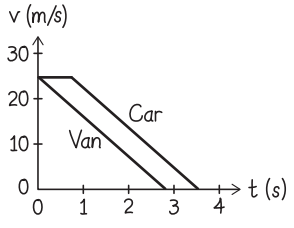
- Sketch the situation described in the problem. Choose the object of interest.
- Include an object of reference and a coordinate system. Indicate the origin and the positive direction.
- Label the sketch with relevant information.
- Identify the unknown that you need to find. Label it with a question mark on the sketch.

Simplify and diagram



- Decide how you will model each moving object (for example, as a point-like object).
- Can you model the motion as constant velocity or constant acceleration?
- Draw motion diagrams and kinematics graphs if needed.

EXAMPLE 2.12 **An accident involving tailgating**



A car follows about two car lengths (10.0 m) behind a van. At first, both vehicles are traveling at a conservative speed of 25 m/s (56 mi/h). The driver of the van suddenly slams on the brakes to avoid an accident, slowing down at 9.0 m/s^2. The car driver's reaction time is 0.80 s and the car's maximum acceleration while slowing down is also 9.0 m/s^2. Will the car be able to stop before hitting the van?

Below we represent this situation for each vehicle (we have two objects of interest). We use capital letters to indicate quantities referring to the van and lowercase letters for quantities referring to the car. We use the coordinate system shown with the origin of the coordinates at the initial position of the car's front bumper. The positive direction is in the direction of motion.

The process starts when the van starts braking. The van moves at constant negative acceleration throughout the entire process. We separate the motion of the car into two parts: (1) its motion before the driver applies the brakes (constant positive velocity) and (2) its motion after the driver starts braking (constant negative acceleration).

We model each vehicle as a point-like object, but since we are trying to determine if they collide, we need to be more specific about their positions. The position of the car is the position of its front bumper. The position of the van is the position of its rear bumper. We look at the motion of each vehicle separately. If the car's final position is greater than the van's final position, then a collision has occurred at some point during their motion. Assume that the vehicles have constant acceleration so that we can apply our model of motion with constant acceleration. A velocity-versus-time graph line for each vehicle is shown at right.

Represent mathematically

- Use the sketch(es), motion diagram(s), and kinematics graph(s) to construct a mathematical representation (equations) of the process. Be sure to consider the sign of each quantity.

Equation (2.7) can be used to determine the distance the van travels while stopping:

$$2A_x(X - X_0) = V_x^2 - V_{0x}^2 \Rightarrow X = \frac{V_x^2 - V_{0x}^2}{2A_x} + X_0$$

The car Part 1 Since the car is initially traveling at constant velocity, we use Eq. (2.2). The subscript 0 indicates the moment the driver sees the van start slowing down. The subscript 1 indicates the moment the car driver starts braking.

$$x_1 = x_0 + v_{0x}t_1$$

The car Part 2 After applying the brakes, the car has an acceleration of $-9.0\ \text{m/s}^2$. The subscript 2 indicates the moment the car stops moving. We represent this part of the motion using Eq. (2.7):

$$2a_x(x_2 - x_1) = v_{2x}^2 - v_{1x}^2$$
$$\Rightarrow x_2 = \frac{v_{2x}^2 - v_{1x}^2}{2a_x} + x_1 \Rightarrow x_2 = \frac{v_{2x}^2 - v_{1x}^2}{2a_x} + (x_0 + v_{0x}t_1)$$

The last step came from inserting the result from Part 1 for x_1.

Solve and evaluate

- Solve the equations to find the answer to the question you are investigating.
- Evaluate the results to see if they are reasonable. Check the units and decide if the calculated quantities have reasonable values (sign, magnitude). Check limiting cases: examine whether the final equation leads to a reasonable result if one of the quantities is zero or infinity. This strategy applies when you derive a new equation while solving a problem.

The van's initial velocity is $V_0 = +25\ \text{m/s}$, its final velocity is $V_x = 0$, and its acceleration is $A = -9.0\ \text{m/s}^2$. Its initial position is two car lengths in front of the front of the car, so $X_0 = 2 \times 5.0\ \text{m} = 10\ \text{m}$. The final position of the van is

$$X = \frac{V_x^2 - V_{0x}^2}{2A_x} + X_0 = \frac{0^2 - (25\ \text{m/s})^2}{2(-9.0\ \text{m/s}^2)} + 10\ \text{m} = 45\ \text{m}$$

The car's initial position is $x_0 = 0$, its initial velocity is $v_{0x} = 25\ \text{m/s}$, its final velocity is $v_{2x} = 0$, and its acceleration when braking is $a_x = -9.0\ \text{m/s}^2$. The car's final position is

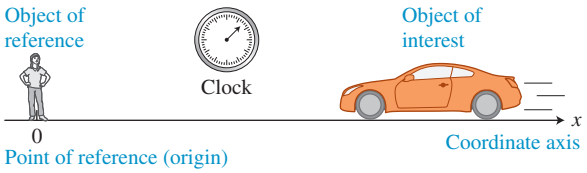
$$x_2 = \frac{v_{2x}^2 - v_{1x}^2}{2a_x} + (x_0 + v_{0x}t_1) = \frac{0^2 - (25\ \text{m/s})^2}{2(-9.0\ \text{m/s}^2)} + [0\ \text{m} + (25\ \text{m/s})(0.8\ \text{s})] = 55\ \text{m}$$

The car will stop about 10 m beyond where the van will stop. There will be a collision between the two vehicles.

This analysis illustrates why tailgating is such a big problem. The car traveled at a 25-m/s constant velocity during the relatively short 0.80-s reaction time. During the same 0.80 s, the van's velocity decreased by $(0.80\ \text{s})(-9.0\ \text{m/s}^2) = 7.2\ \text{m/s}$ from 25 m/s to about 18 m/s. So the van was moving somewhat slower than the car when the car finally started to brake. Since they were both slowing down at about the same rate, the tailgating vehicle's velocity was always greater than that of the vehicle in front until they hit.

Try it yourself Two cars, one behind the other, are traveling at 30 m/s (67 mi/h). The front car hits the brakes and slows down at the rate of $10\ \text{m/s}^2$. The driver of the second car has a 1.0-s reaction time. The front car's speed has decreased to 20 m/s during that 1.0 s. The rear car traveling at 30 m/s starts braking, slowing down at the same rate of $10\ \text{m/s}^2$. How far behind the front car should the rear car be so it does not hit the front car?

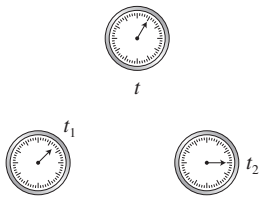
Answer The rear car should be at least 30 m behind the front car.



REVIEW QUESTION 2.9 A car's motion with respect to the ground is described by the following function:

$$x = (-48\ \text{m}) + (12\ \text{m/s})t + (-2.0\ \text{m/s}^2)t^2$$

Mike says that its original position is $(-48\ \text{m})$ and its acceleration is $(-2.0\ \text{m/s}^2)$. Do you agree? If yes, explain why; if not, explain how to correct his answer.



Summary

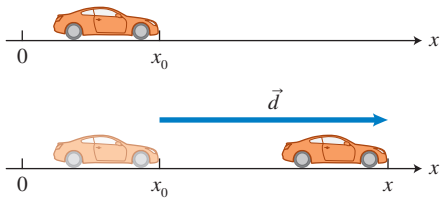
A **reference frame** consists of an object of reference, a point of reference on that object, a coordinate system whose origin is at the point of reference, and a clock. (Section 2.1)

Time or clock reading t (a scalar quantity) is the reading on a clock or another time measuring instrument. (Section 2.4)

Time interval Δt (a scalar quantity) is the difference of two times. (Section 2.4)

Time: t

Time interval:



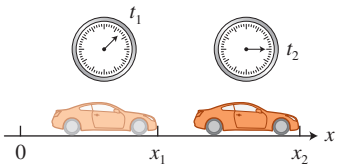
$$\Delta t = t_2 - t_1$$

Position x (a scalar quantity) is the location of an object relative to the chosen origin. (Section 2.4)

Displacement $\vec{d}$ is a vector drawn from the initial position of an object to its final position. The x-component of the displacement d_x is the change in position of the object along the x-axis. (Section 2.4)

Distance d (a scalar quantity) is the magnitude of the displacement and is always positive. (Section 2.4)

Path length l is the length of a string laid along the path the object took. (Section 2.4)



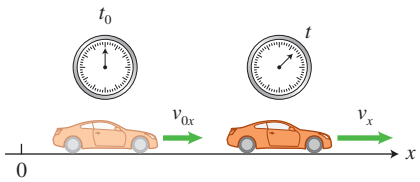
$d_x = x - x_0 > 0$ if $\vec{d}$ points in the positive direction of x-axis.

$d_x = x - x_0 < 0$ if $\vec{d}$ points in the negative direction.

$$d = |x - x_0|$$

Velocity $\vec{v}$ (a vector quantity) is the ratio of the displacement of an object during a time interval to that time interval. The velocity is *instantaneous* if the time interval is very small and *average* if the time interval is longer. (Section 2.6)

Speed v (a scalar quantity) is the magnitude of the velocity. (Section 2.6)



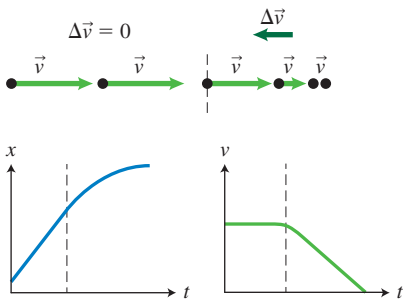
For constant velocity linear motion,

$$\vec{v} = \vec{d}/\Delta t$$

$$v_x = \frac{\Delta x}{\Delta t} = \frac{x_2 - x_1}{t_2 - t_1} \qquad \text{Eq. (2.1)}$$

$$v = \left|\frac{\Delta x}{\Delta t}\right|$$

Acceleration $\vec{a}$ (a vector quantity) is the ratio of the change in an object's velocity $\Delta\vec{v}$ during a time interval Δt to the time interval. The acceleration is *instantaneous* if the time interval is very small and *average* if the time interval is longer. (Section 2.7)



$$a_x = \frac{v_{2x} - v_{1x}}{t_2 - t_1} = \frac{\Delta v_x}{\Delta t} \qquad \text{Eq. (2.4)}$$

(rearranged)

$$a_x = \frac{\Delta v_x}{\Delta t} = \frac{v_x - v_{0x}}{t - t_0} \qquad \text{Eq. (2.4)}$$

Motion with constant velocity or constant acceleration can be represented with a sketch, a motion diagram, kinematics graphs, and mathematically. (Sections 2.6—2.9)

$$v_x = v_{0x} + a_x t \qquad \text{Eq. (2.5)}$$

$$x = x_0 + v_{0x}t + \tfrac{1}{2}a_x t^2 \qquad \text{Eq. (2.6)}$$

$$2a_x(x - x_0) = v_x^2 - v_{0x}^2 \qquad \text{Eq. (2.7)}$$

(rearranged)

$$x - x_0 = \frac{v_x^2 - v_{0x}^2}{2a_x} \qquad \text{Eq. (2.7)}$$

Questions

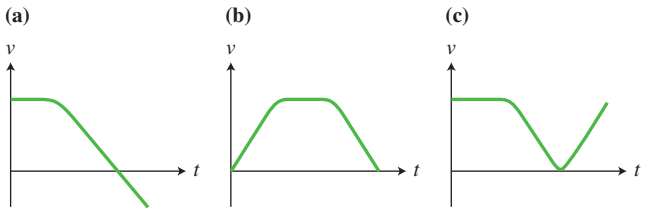
Multiple Choice Questions

1. Match the general elements of physics knowledge (left) with the appropriate examples (right).

Model of a process	Free fall
Model of an object	Acceleration
Physical quantity	Rolling ball
Physical phenomenon	Point-like object

   (a) Model of a process—Acceleration; Model of an object—Point-like object; Physical quantity—Free fall; Physical phenomenon—Rolling ball.
   (b) Model of a process—Rolling ball; Model of an object—Point-like object; Physical quantity—Acceleration; Physical phenomenon—Free fall.
   (c) Model of a process—Free fall; Model of an object—Point-like object; Physical quantity—Acceleration; Physical phenomenon—Rolling ball.

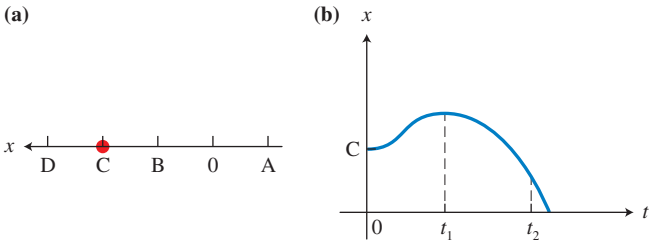
2. Which group of quantities below consists only of scalar quantities?
   (a) Average speed, displacement, time interval
   (b) Average speed, path length, clock reading
   (c) Temperature, acceleration, position



3. Which of the following are examples of time interval?
   (1) I woke up at 7 a.m. (2) The lesson lasted 45 minutes. (3) Svetlana was born on November 26. (4) An astronaut orbited Earth in 4 hours.
   (a) 1, 2, 3, and 4 (b) 2 and 4 (c) 2
   (d) 4 (e) 3

4. A student said, "The displacement between my dorm and the lecture hall is 1 kilometer." Is he using the correct physical quantity for the information provided? What should he have called the 1 kilometer?
   (a) Distance (b) Path length (c) Position
   (d) Both a and b are correct.

5. An object moves so that its position depends on time as $x = +12\text{ m} - (4\text{ m/s})t + (1\text{ m/s}^2)t^2$. Which statement below is not true?
   (a) The object is accelerating.
   (b) The speed of the object is always decreasing.
   (c) The object first moves in the negative direction and then in the positive direction.
   (d) The acceleration of the object is $+2\text{ m/s}^2$.
   (e) The object stops for an instant at 2.0 s.



6. Choose the correct approximate velocity-versus-time graph for the following hypothetical motion: a car moves at constant velocity, and then slows to a stop and without a pause moves in the opposite direction with the same acceleration (**Figure Q2.6**).

FIGURE Q2.6

7. **Figure Q2.7b** shows the position-versus-time graph for a small red dot that was moving along the x-axis from point C at $t = 0$, as shown in Figure Q2.7a. Select the two answers that correctly describe the motion of the dot.

FIGURE Q2.7

   (a) At t_1 the velocity of the dot was zero.
   (b) At t_1 the speed of the dot was greatest.
   (c) At t_1 the dot was at position D.
   (d) At t_2 the dot was at position A.
   (e) At t_2 the velocity of the dot was positive.

8. Oliver takes two identical marbles and drops the first one from a certain height. A short time later, he drops the second one from the same height. How does the distance between the marbles change while they are falling to the ground? Choose the best answer and explanation.
   (a) The distance increases because the first marble moves faster than the second marble at every instant of time.
   (b) The distance increases because the first marble moves with greater acceleration than the second marble.
   (c) The distance stays the same because both marbles are falling with the same acceleration.
   (d) The distance stays the same because the velocities of the marbles are equal at every instant of time.

9. Your car is traveling west at 12 m/s. A stoplight (the origin of the coordinate axis) to the west of you turns yellow when you are 20 m from the edge of the intersection (see **Figure Q2.9**). You apply the brakes and your car's speed decreases. Your car stops before it reaches the stoplight. What are the signs for the components of kinematics quantities?

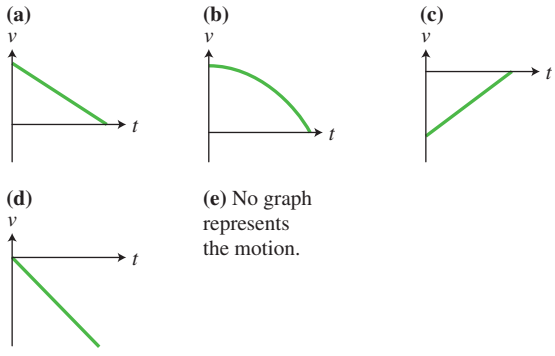


FIGURE Q2.9

	x_0	v_{0x}	a_x
(a)	+	−	−
(b)	+	−	+
(c)	+	+	−
(d)	+	+	+
(e)	−	−	+

10. Which velocity-versus-time graph in **Figure Q2.10** best describes the motion of the car in the previous problem (see Figure Q2.9) as it approaches the stoplight?

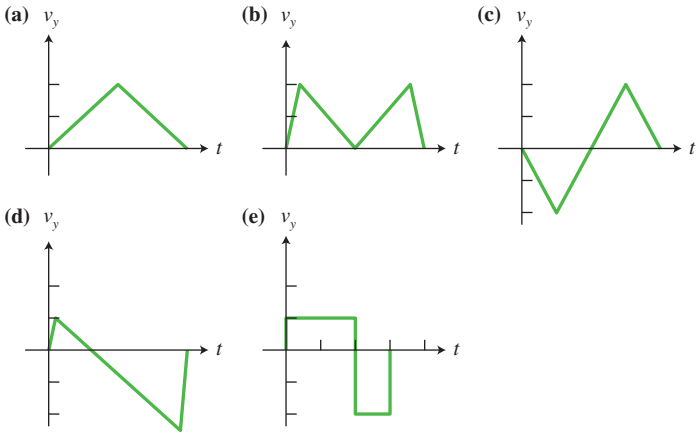

FIGURE Q2.10

(e) No graph represents the motion.

11. Azra wants to determine the average speed of the high-speed train that operates between Paris and Lyon. Before she boards the train, she measures the length of the train L and the distance d between the electric line poles that are placed along the tracks. Which of the following procedures should she use?
    (a) Divide the distance between the adjacent poles by 10 times the time needed to pass 10 poles.
    (b) Divide the length of the train by $\frac{1}{10}$ of the time needed to pass 10 poles.
    (c) Count how many poles the train passed in 10 s and divide this number by $d \cdot 10$ s.
    (d) Count how many poles the train passed in 10 s and multiply this number by $\frac{d}{10\text{ s}}$.
12. A sandbag hangs from a rope attached to a rising hot air balloon. The rope connecting the bag to the balloon is cut. How will two observers see the motion of the sandbag? Observer 1 is in the hot air balloon and observer 2 is on the ground?
    (a) Both 1 and 2 will see it go down.
    (b) 1 will see it go down and 2 will see it go up.
    (c) 1 will see it go down and 2 will see it go up and then down.
13. An apple falls from a tree. It hits the ground at a speed of about 5.0 m/s. What is the approximate height of the tree?
    (a) 2.5 m (b) 1.3 m (c) 10.0 m (d) 2.4 m
14. You have two small metal balls. You drop the first ball and throw the other one in the downward direction. Choose the statements that are not correct.
    (a) The second ball will spend less time in flight.
    (b) The first ball will have a slower final speed when it reaches the ground.
    (c) The second ball will have larger acceleration.
    (d) Both balls will have the same acceleration.
15. Which of the graphs in **Figure Q2.15** represent the motion of an object that starts from rest and then, after undergoing some motion, returns to its initial position? Multiple answers could be correct.

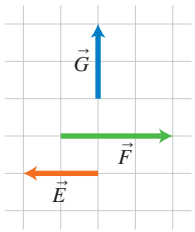

FIGURE Q2.15

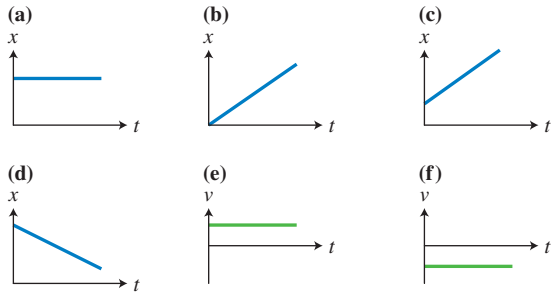
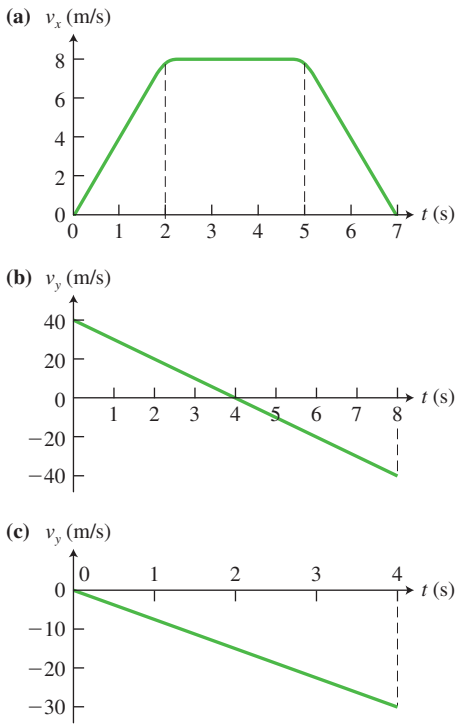
16. You throw a small ball upward and notice the time it takes to come back. If you then throw the same ball so that it takes twice as much time to come back, what is true about the motion of the ball the second time?
    (a) Its initial speed was twice the speed in the first experiment.
    (b) It traveled an upward distance that is twice the distance of the original toss.
    (c) It had twice as much acceleration on the way up as it did the first time.
    (d) The ball stopped at the highest point and had zero acceleration at that point.



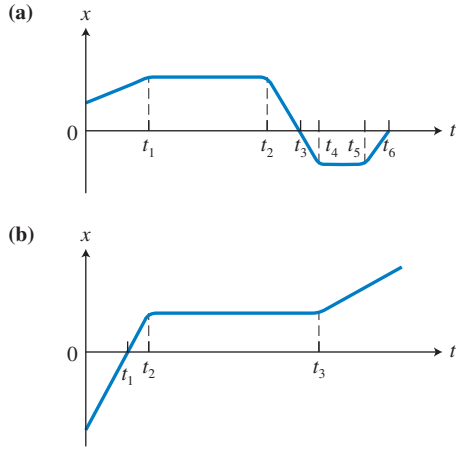
Conceptual Questions

FIGURE Q2.17



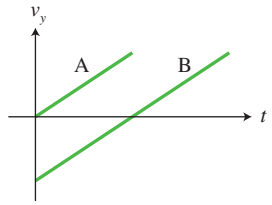
17. **Figure Q2.17** shows vectors $\vec{E}$, $\vec{F}$, and $\vec{G}$. Draw the following vectors using rules for graphical addition and subtraction:
    (a) $\vec{E} + \vec{F}$, (b) $\vec{E} - \vec{F}$,
    (c) $\vec{E} + \vec{G}$, (d) $-\vec{G} + \vec{F}$,
    (e) $\vec{E} + \vec{F} + \vec{G}$, and (f) $\vec{E} - \vec{F} + \vec{G}$.
18. Peter is cycling along an 800-m straight stretch of a track. His speed is 13 m/s. Choose all of the graphical representations of motion from **Figure Q2.18** that correctly describe Peter's motion.

FIGURE Q2.18



19. In what reasonable ways can you represent or describe the motion of a car traveling from one stoplight to the next? Construct each representation for the moving car.
20. What is the difference between speed and velocity? Between path length and distance? Between distance and displacement? Give an example of each.
21. What physical quantities do we use to describe motion? What does each quantity characterize? What are their SI units?
22. Devise stories describing each of the motions shown in each of the graphs in **Figure Q2.22**. Specify the object of reference.

FIGURE Q2.22



23. For each of the position-versus-time graphs in **Figure Q2.23**, draw velocity-versus-time graphs and acceleration-versus-time graphs.

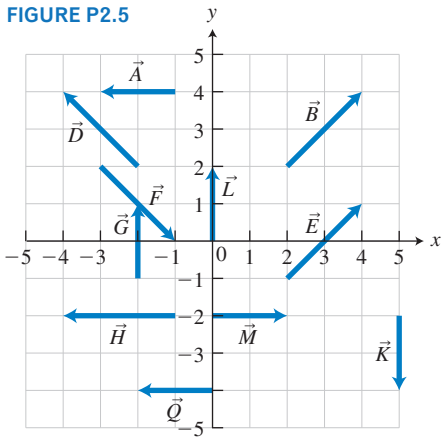
FIGURE Q2.23

24. **Figure Q2.24** shows velocity-versus-time graphs for two objects, A and B. Draw motion diagrams that correspond to the motion of these two objects.
25. Can an object have a nonzero velocity and zero acceleration? If so, give an example.
26. Can an object at one instant of time have zero velocity and nonzero acceleration? If so, give an example.
27. Your little sister has a battery-powered toy truck. When the truck is moving, how can you determine whether it has constant velocity, constant speed, constant acceleration, or changing acceleration? Explain in detail.
28. You throw a ball upward. Your friend says that at the top of its flight the ball has zero velocity and zero acceleration. Do you agree or disagree? If you agree, explain why. If you disagree, how would you convince your friend of your opinion?

FIGURE Q2.24

Problems

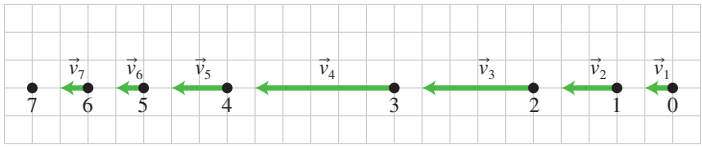
Below, BIO indicates a problem with a biological or medical focus. Problems labeled EST ask you to estimate the answer to a quantitative problem rather than derive a specific answer. Asterisks indicate the level of difficulty of the problem. Problems with no * are considered to be the least difficult. A single * marks moderately difficult problems. Two ** indicate more difficult problems.



2.2 A conceptual description of motion

1. A car starts at rest from a stoplight and speeds up. It then moves at constant speed for a while. Then it slows down until reaching the next stoplight. Represent the motion with a motion diagram as seen by the observer on the ground.
2. * You are an observer on the ground. (a) Draw two motion diagrams representing the motions of two runners moving at the same constant speeds in opposite directions toward you. Runner 1, coming from the east, reaches you in 5 s, and runner 2 reaches you in 3 s. (b) Draw a motion diagram for the second runner as seen by the first runner.
3. * A car is moving at constant speed on a highway. A second car catches up and passes the first car 5 s after it starts to speed up. Represent the situation with a motion diagram. Specify the observer with respect to whom you drew the diagram.
4. * A hat falls off a man's head and lands in the snow. Draw a motion diagram representing the motion of the hat as seen by the man.

2.3 Operations with vectors



5. **Figure P2.5** shows several displacement vectors that are all in the (x, y) plane. (a) List all displacement vectors with a scalar component equal to -2 units. (b) List all displacement vectors with a scalar component equal to 0 units. (c) List all displacement vectors that represent the distance traveled of 2 units. (d) Find three vectors that are related as $\vec{X} + \vec{Y} = \vec{Z}$ and three that are related as $\vec{X} - \vec{Y} = \vec{Z}$.

FIGURE P2.5

6. **Figure P2.6** shows an incomplete motion diagram for an object. (a) For each pair of adjacent velocities, draw a corresponding $\Delta\vec{v}$ vector. Use the grid to determine their lengths accurately. (b) Explain how to construct a $\Delta\vec{v}$ vector by using the rule for addition of vectors and how to do it using the rule for subtraction of vectors.

FIGURE P2.6

2.4 and 2.5 Quantities for describing motion and Representing motion with data tables and graphs

7. * You drive 100 km east, do some sightseeing, and then turn around and drive 50 km west, where you stop for lunch. (a) Represent your trip with a displacement vector. Choose an object of reference and coordinate axis so that the scalar component of this vector is (b) positive; (c) negative; (d) zero.
8. * Choose an object of reference and a set of coordinate axes associated with it. Show how two people can start and end their trips at different locations but still have the same displacement vectors in this reference frame.
9. The scalar x-component of a displacement vector for a trip is -70 km. Represent the trip using a coordinate axis and an object of reference. Then change the axis so that the displacement component becomes $+70$ km.
10. * You recorded your position with respect to the front door of your house as you walked to the mailbox. Examine the data presented in **Table 2.8** and answer the following questions: (a) What instruments might you have used to collect data? (b) Represent your motion using a position-versus-time graph. (c) Tell the story of your motion in words. (d) Show on the graph the displacement, distance, and path length.

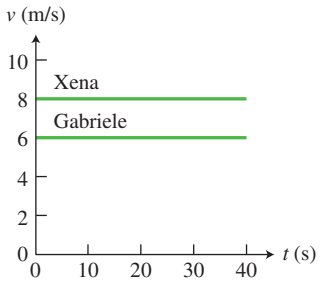


TABLE 2.8

t (s)	1	2	3	4	5	6	7	8	9
x (steps)	2	4	9	13	18	20	16	11	9

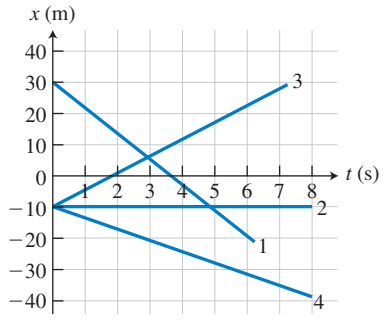
2.6 Constant velocity linear motion

11. * You need to determine the time interval (in seconds) needed for light to pass an atomic nucleus. What information do you need? How will you use it? What simplifying assumptions about the objects and processes do you need to make? What approximately is that time interval?
12. A speedometer reads 65 mi/h. (a) Use as many different units as possible to represent the speed of the car. (b) If the speedometer reads 100 km/h, what is the car's speed in mi/h?
13. Convert the following record speeds so that they are in mi/h, km/h, and m/s. (a) Australian dragonfly—36 mi/h; (b) the diving peregrine falcon—349 km/h; and (c) the Lockheed SR-71 jet aircraft—980 m/s (about three times the speed of sound).
14. EST **Hair growth speed** Estimate the rate that your hair grows in meters per second. Indicate any assumptions you made.
15. * EST A kidnapped banker looking through a slit in a van window counts her heartbeats and observes that two highway exits pass in 80 heartbeats. She knows that the distance between the exits is 1.6 km (1 mile). (a) Estimate the van's speed. (b) Choose and describe a reference frame and draw a position-versus-time graph for the van.
16. * Some computer scanners scan documents by moving the scanner head with a constant speed across the document. A scanner can scan up to 30 pages per minute using an automatic paper feed tray. Estimate the maximum speed of the scanner head when scanning a standard letter sheet (21.59 cm × 27.94 cm). Indicate any assumptions that you made.
17. * **Equation Jeopardy** Two observers observe two different moving objects. However, they describe their motions mathematically with the same equation: $x(t) = 10\text{ km} - (4\text{ km/h})t$. (a) Write two short stories about these two motions. Specify where each observer is and what she is doing. What is happening to the moving object at $t = 0$? (b) Use significant digits to determine the interval within which the initial position is known.
18. * Your friend's pedometer shows that he took 17,000 steps in 2.50 h during a hike. Determine everything you can about the hike. What assumptions did you make? How certain are you in your answer? How would the answer change if the time were given as 2.5 h instead of 2.50 h?
19. During a hike, two friends were caught in a thunderstorm. Four seconds after seeing lightning from a distant cloud, they heard thunder. How far away was the cloud (in kilometers)? Write your answer as an interval using significant digits as your guide. Sound travels in air at about 340 m/s.
20. Light travels at a speed of 3.0×10^8 m/s in a vacuum. The approximate distance between Earth and the Sun is 150×10^6 km. How long does it take light to travel from the Sun to Earth? What are the margins within which you know the answer?
21. Proxima Centauri is 4.22 ± 0.01 light-years from Earth. Determine the length of 1 light-year and convert the distance to the star into meters. What is the uncertainty in the answer?
22. * Spaceships traveling to other planets in the solar system move at an average speed of 1.1×10^4 m/s. It took Voyager about 12 years to reach the orbit of Uranus. What can you learn about the solar system using these data? What assumption did you make? How did this assumption affect the results?
23. ** **Figure P2.23** shows a velocity-versus-time graph for the bicycle trips of two friends with respect to the parking lot where they started. (a) Determine their displacements in 20 s. (b) If Xena's position at time zero is 0 and Gabriele's position is 60 m, what time interval is needed for Xena to catch Gabriele? (c) Use the information from (b) to write the function $x(t)$ for Gabriele with respect to Xena.

FIGURE P2.23

24. * **Table 2.9** shows position and time data for your walk along a straight path. (a) Tell everything you can about the walk. Specify the object of reference. (b) Draw a motion diagram, draw a graph $x(t)$, and write a function $x(t)$ that is consistent with the data and the chosen reference frame.

TABLE 2.9



Time (s)	Position (m)
0	80
10	40
20	0
30	−40
40	−80
50	−120

TABLE 2.10

Time (s)	Position (m)
0	−200
10	−120
20	−40
30	40
40	120
50	200

25. * **Table 2.10** shows position and time data for your friend's bicycle ride along a straight bike path. (a) Tell everything you can about his ride. Specify the observer. (b) Draw a motion diagram, draw a graph $x(t)$, and write a function $x(t)$ that is consistent with the ride.
26. * You are walking to your physics class at speed 1.0 m/s with respect to the ground. Your friend leaves 2.0 min after you and is walking at speed 1.3 m/s in the same direction. How fast is she walking with respect to you? How far does your friend travel before she catches up with you? Indicate the uncertainty in your answers. Describe any assumptions that you made.
27. * Gabriele enters an east–west straight bike path at the 3.0-km mark and rides west at a constant speed of 8.0 m/s. At the same time, Xena rides east from the 1.0-km mark at a constant speed of 6.0 m/s. (a) Write functions $x(t)$ that describe their positions as a function of time with respect to Earth. (b) Where do they meet each other? In how many different ways can you solve this problem? (c) Write a function $x(t)$ that describes Xena's motion with respect to Gabriele.
28. * Jim is driving his car at 32 m/s (72 mi/h) along a highway where the speed limit is 25 m/s (55 mi/h). A highway patrol car observes him pass and quickly reaches a speed of 36 m/s. At that point, Jim is 300 m ahead of the patrol car. How far does the patrol car travel before catching Jim?
29. * You hike two-thirds of the way to the top of a hill at a speed of 3.0 mi/h and run the final third at a speed of 6.0 mi/h. What was your average speed?
30. * Olympic champion swimmer Michael Phelps swam at an average speed of 2.01 m/s during the first half of the time needed to complete a race. What was his average swimming speed during the second half of the race if he tied the record, which was at an average speed of 2.05 m/s?
31. * A car makes a 100-km trip. It travels the first 50 km at an average speed of 50 km/h. How fast must it travel the second 50 km so that its average speed is 100 km/h?
32. * Jane and Bob see each other when 100 m apart. They are moving toward each other, Jane at constant speed 4.0 m/s and Bob at constant speed 3.0 m/s with respect to the ground. What can you determine about this situation using these data?
33. * The graph in **Figure P2.33** represents four different motions. (a) Write a function $x(t)$ for each motion. (b) Use the information in the graph to determine as many quantities related to the motion of these objects as possible. (c) Act out these motions with two friends. (Hint: Think of what each object was doing at $t = 0$.)

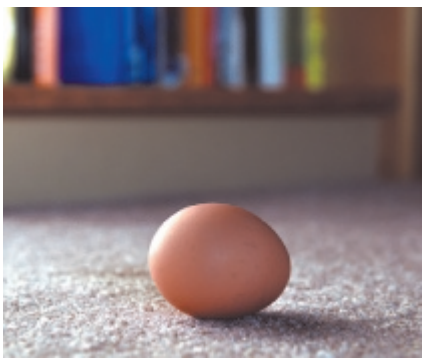


FIGURE P2.33

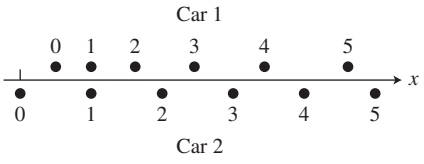
2.7 and 2.8 Motion at constant acceleration and Displacement of an object moving at constant acceleration

34. A car starts from rest and reaches the speed of 10 m/s in 30 s. What can you determine about the motion of the car using this information?
35. A truck is traveling east at +16 m/s. (a) The driver sees that the road is empty and accelerates at +1.0 m/s^2 for 5.0 s. What can you determine about the truck's motion using these data? (b) The driver then sees a red light ahead and decelerates at −2.0 m/s^2 for 3.0 s. What can you determine about the truck's motion using these data? (c) Determine the values of the quantities you listed in (a) and (b).
36. **Bumper car collision** On a bumper car ride, friends smash their cars into each other (head-on), and each has a speed *change* of 3.2 m/s. If the magnitudes of acceleration of each car during the collision averaged 28 m/s^2, determine the time interval needed to stop and the stopping distance for each car while colliding. Specify your reference frame.
37. A bus leaves an intersection accelerating at +2.0 m/s^2. Where is the bus after 5.0 s? What assumption did you make? If this assumption is not valid, would the bus be closer or farther away from the intersection compared to your original answer? Explain.
38. A jogger is running at +4.0 m/s when a bus passes her. The bus is accelerating from +16.0 m/s to +20.0 m/s in 8.0 s. The jogger speeds up with the same acceleration. What can you determine about the jogger's motion using these data?
39. * The motion of a person as seen by another person is described by the equation $v = -3.0\ \text{m/s} + (0.5\ \text{m/s}^2)t$. (a) Represent this motion with a motion diagram and position-, velocity-, and acceleration-versus-time graphs. (b) Say everything you can about this motion and describe what happens to the person when his speed becomes zero.
40. While cycling at a speed of 10 m/s, a cyclist starts going downhill with an acceleration of magnitude 1.2 m/s^2. The descent takes 10.0 s. What can you determine about the cyclist's motion using these data? What assumptions did you make?
41. * EST To his surprise, Daniel found that an egg did not break when he accidentally dropped it from a height of 0.40 m onto his floor, covered with 2.0-cm-thick carpet. Estimate the minimum acceleration of the egg while it was slowing down after touching the carpet. Indicate any assumptions you made.

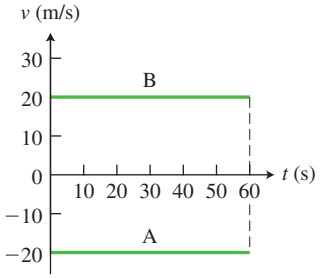
FIGURE P2.41



42. BIO **Squid propulsion** *Lolliguncula brevis* squid use a form of jet propulsion to swim—they eject water out of jets that can point in different directions, allowing them to change direction quickly. When swimming at a speed of 0.15 m/s or greater, they can accelerate at 1.2 m/s^2. (a) Determine the time interval needed for a squid to increase its speed from 0.15 m/s to 0.45 m/s. (b) What other questions can you answer using the data?
43. **Dragster record on the desert** In 1977, Kitty O'Neil drove a hydrogen peroxide–powered rocket dragster for a record time interval (3.22 s) and final speed (663 km/h) on a 402-m-long Mojave Desert track. Determine her average acceleration during the race and the acceleration while stopping (it took about 20 s to stop). What assumptions did you make?
44. * Imagine that a sprinter accelerates from rest to a maximum speed of 10.8 m/s in 1.8 s. In what time interval will he finish the 100-m race if he keeps his speed constant at 10.8 m/s for the last part of the race? What assumptions did you make?
45. ** Two runners are running next to each other when one decides to speed up at constant acceleration a. The second runner notices the acceleration after a short time interval Δt when the distance between the runners is d. The second runner accelerates at the same acceleration. Represent their motions with a motion diagram and position-versus-time graph (both graph lines on the same set of axes). Use any of the representations to predict what will happen to the distance between the runners—will it stay d, increase, or decrease? Assume that the runners continue to have the same acceleration for the duration of the problem.
46. * **Meteorite hits car** In 1992, a 14-kg meteorite struck a car in Peekskill, NY, leaving a 20-cm-deep dent in the trunk. (a) If the meteorite was moving at 500 m/s before striking the car, what was the magnitude of its acceleration while stopping? Indicate any assumptions you made. (b) What other questions can you answer using the data in the problem?
47. BIO **Froghopper jump** A spittlebug called the froghopper (*Philaenus spumarius*) is believed to be the best jumper in the animal world. It pushes off with muscular rear legs for 0.0010 s, reaching a speed of 4.0 m/s. Determine its acceleration during this launch and the distance that the froghopper moves while its legs are pushing.
48. **Tennis serve** The fastest server in women's tennis is Sabine Lisicki, who recorded a serve of 131 mi/h (211 km/h) in 2014. If her racket pushed on the ball for a distance of 0.10 m, what was the average acceleration of the ball during her serve? What was the time interval for the racket-ball contact?
49. * **Shot from a cannon** In 1998, David "Cannonball" Smith set the distance record for being shot from a cannon (56.64 m). During a launch in the cannon's barrel, his speed increased from zero to 80 km/h in 0.40 s. While he was being stopped by the catching net, his speed decreased from 80 km/h to zero with an average acceleration of 180 m/s^2. What can you determine about Smith's flight using this information?
50. **Col. John Stapp's final sled run** Col. John Stapp led the U.S. Air Force Aero Medical Laboratory's research into the effects of higher accelerations. On Stapp's final sled run, the sled reached a speed of 282.5 m/s (632 mi/h) and then stopped with the aid of water brakes in 1.4 s. Stapp was barely conscious and lost his vision for several days but recovered. Determine his acceleration while stopping and the distance he traveled while stopping.
51. * Sprinter Usain Bolt reached a maximum speed of 11.2 m/s in 2.0 s while running the 100-m dash. (a) What was his acceleration? (b) What distance did he travel during this first 2.0 s of the race? (c) What assumptions did you make? (d) What time interval was needed to complete the race, assuming that he ran the last part of the race at his maximum speed? (e) What is the total time for the race? How certain are you of the number you calculated?
52. ** Imagine that Usain Bolt can reach his maximum speed in 1.7 s. What should be his maximum speed in order to tie the 19.19-s record for the 200-m dash?
53. * A bus is moving at a speed of 36 km/h. How far from a bus stop should the bus start to slow down so that the passengers feel comfortable (a comfortable acceleration is 1.2 m/s^2)?
54. * EST You want to estimate how fast your car accelerates. What information can you collect to answer this question? What assumptions do you need to make to do the calculation using the information?
55. * In your car, you covered 2.0 m during the first 1.0 s, 4.0 m during the second 1.0 s, 6.0 m during the third 1.0 s, and so forth. Was this motion at constant acceleration? Explain.
56. (a) Determine the acceleration of a car in which the velocity changes from −10 m/s to −20 m/s in 4.0 s. (b) Determine the car's acceleration if its velocity changes from −20 m/s to −18 m/s in 2.0 s. (c) Explain why the sign of the acceleration is different in (a) and (b).
57. You accidentally drop an eraser out the window of an apartment 15 m above the ground. (a) How long will it take for the eraser to reach the ground? (b) What speed will it have just before it reaches the ground? (c) If you multiply the time interval answer from (a) and the speed answer from (b), why is the result much more than 15 m?
58. * What is the average speed of the eraser in the previous problem from the instant it is released to the instant it reaches the ground?
59. You throw a tennis ball straight upward. The initial speed is about 12 m/s. Say everything you can about the motion of the ball. Is 12 m/s a realistic speed for an object that you can throw with your hands?
60. While skydiving, your parachute opens and you slow from 50.0 m/s to 8.0 m/s in 0.80 s. Determine the distance you fall while the parachute is opening. Some people faint if they experience acceleration greater than 5g (5 times 9.8 m/s^2). Will you feel faint? Explain and discuss simplifying assumptions inherent in your explanation.

61. * After landing from your skydiving experience, you are so excited that you throw your helmet upward. The helmet rises 5.0 m above your hands. What was the initial speed of the helmet when it left your hands? How long was it moving from the time it left your hands until it returned?
62. * You are standing on the rim of a canyon. You drop a rock and in 7.0 s hear the sound of it hitting the bottom. How deep is the canyon? What assumptions did you make? Examine how each assumption affects the answer. Does it lead to a larger or smaller depth than the calculated depth? (The speed of sound in air is about 340 m/s.)
63. * You are doing an experiment to determine your reaction time. Your friend holds a ruler. You place your fingers near the sides of the lower part of the ruler without touching it. The friend drops the ruler without warning you. You catch the ruler after it falls 12.0 cm. What was your reaction time?
64. EST **Cliff divers** Divers in Acapulco fall 36 m from a cliff into the water. Estimate their speed when they enter the water and the time interval needed to reach the water. What assumption did you make? Does this assumption make the calculated speed larger or smaller than actual speed?
65. * Galileo dropped a light rock and a heavy rock from the Leaning Tower of Pisa, which is about 55 m high. Suppose that Galileo dropped one rock 0.50 s before the second rock. With what initial velocity should he drop the second rock so that it reaches the ground at the same time as the first rock?
66. * A person holding a lunch bag is moving upward in a hot air balloon at a constant speed of 7.0 m/s. When the balloon is 24 m above the ground, she accidentally releases the bag. What is the speed of the bag just before it reaches the ground?
67. * A parachutist falling vertically at a constant speed of 10 m/s drops a penknife when 20 m above the ground. What is the speed of the knife just before it reaches the ground?

2.9 Skills for analyzing situations involving motion

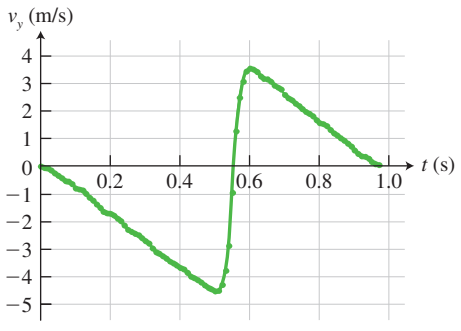


68. A diagram representing the motion of two cars is shown in **Figure P2.68**. The number near each dot indicates the clock reading in seconds when the car passes that location. (a) Indicate times when the cars have the same speed. (b) Indicate times when they have the same position.

FIGURE P2.68

69. Use the velocity-versus-time graph lines in **Figure P2.69** to determine the change in the position of each car from 0 s to 60 s. Represent the motion of each car mathematically as a function $x(t)$. Their initial positions are A (200 m) and B $(-200\ \text{m})$.

FIGURE P2.69



70. * An object moves so that its position changes in the following way: $x = 10\ \text{m} - (4\ \text{m/s})t$. (a) Describe all of the known quantities for this motion. (b) Invent a story for the motion. (c) Draw a position-versus-time graph, and use the graph to determine when the object reaches the origin of the reference frame. (e) Act out the motion.
71. * While babysitting their younger brother, Chrisso and Devin are playing with toys. They notice that the squishy Piglet slows down in a repeatable way when they push it along the smooth wooden floor. They propose a hypothesis that the toy slows down with a constant acceleration, which does not depend on the toy's initial velocity. For each of five different initial speeds, they measure the distance traveled by the toy from the time they stop pushing it to the time the toy stops moving, and they measure the corresponding time interval. Their data are presented below. Do the data support their hypothesis? Explain. If yes, determine the average acceleration of Piglet and the maximum speed with which Chrisso and Devin push Piglet.

Experiment #	Distance (m)	Time (s)
1	0.96	0.65
2	2.84	1.12
3	1.72	0.87
4	2.53	1.05
5	0.62	0.53

72. ** An object moves so that its position changes in the following way: $x(t) = -100\ \text{m} + (30\ \text{m/s})t + (3.0\ \text{m/s}^2)t^2$. (a) What kind of motion is this (constant velocity, constant acceleration, or changing acceleration)? (b) Describe all of the known quantities for this motion. (c) Invent a story for the motion. (d) Draw a velocity-versus-time graph, and use it to determine when the object stops. (e) Use equations to determine when and where it stops. Did you get the same answer using graphs and equations?
73. * The positions of objects A and B with respect to Earth depend on time as follows: $x(t)_\text{A} = 10.0\ \text{m} - (4.0\ \text{m/s})t$; $x(t)_\text{B} = -12\ \text{m} + (6\ \text{m/s})t$. Represent their motions on a motion diagram and graphically (position-versus-time and velocity-versus-time graphs). Use the graphical representations to find where and when they will meet. Confirm the result with mathematics.
74. * Two cars on a straight road at time zero are beside each other. The first car, traveling at speed 30 m/s, is passing the second car, which is traveling at 24 m/s. Seeing a cow on the road ahead, the driver of each car starts to slow down at 6.0 m/s^2. Represent the motions of the cars mathematically and on a velocity-versus-time graph from the point of view of a pedestrian. Where is each car when it stops?
75. * Oliver drops a tennis ball from a certain height above a concrete floor. **Figure P2.75** shows the velocity-versus-time graph of the ball's motion from the moment the ball is released to the moment the ball reaches its maximum height after bouncing up from the floor. (a) How is the y-axis directed: up or down? (b) Determine the initial height from which the ball is released and the final height to which the ball bounces. (c) Determine the average speed of the ball during the downward motion.

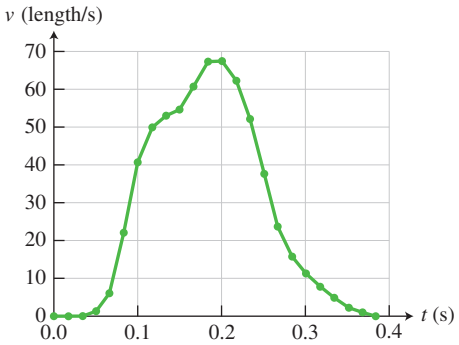


FIGURE P2.75

76. * BIO EST **Water striders** Water striders are insects that propel themselves on the surface of ponds by creating vortices in the water shed by their driving legs. The velocity-versus-time graph of a 17-mm-long water strider that moved in a straight line was created from a video (Figure P2.76). The insect started from rest, sped up by taking two strides, and then slowed down until it stopped. Estimate (a) the maximum speed (in m/s), (b) the maximum acceleration (in m/s^2), and (c) the total displacement (in m) of the water strider. Note that the velocity on the graph is given in units of length of water strider body per second.

FIGURE P2.76

77. You are traveling in your car at 20 m/s a distance of 20 m behind a car traveling at the same speed. The driver of the other car slams on the brakes to stop for a pedestrian who is crossing the street. Will you hit the car? Your reaction time is 0.60 s. The maximum acceleration of each car is $9.0\ m/s^2$.
78. * You are driving a car behind another car. Both cars are moving at speed 80 km/h. What minimum distance behind the car in front should you drive so that you do not crash into the car's rear end if the driver of that car slams on the brakes? Indicate any assumptions you made.
79. * A driver with a 0.80-s reaction time applies the brakes, causing the car to have $7.0\text{-}m/s^2$ acceleration opposite the direction of motion. If the car is initially traveling at 21 m/s, how far does the car travel during the reaction time? How far does the car travel after the brakes are applied and while skidding to a stop?
80. ** Some people in a hotel are dropping water balloons from their open window onto the ground below. The balloons take 0.15 s to pass your 1.6-m-tall window. Where should security look for the raucous hotel guests? Indicate any assumptions that you made in your solution.
81. ** BIO EST **Avoiding injury from hockey puck** Hockey players wear protective helmets with facemasks. Why? Because the bone in the upper part of the cheek (the zygomatic bone) can fracture if the acceleration of a hockey puck due to its interaction with the bone exceeds $900g$ for a time lasting 6.0 ms or longer. Suppose a player was not wearing a facemask. Is it likely that the acceleration of a hockey puck when hitting the bone would exceed these numbers? Use some reasonable numbers of your choice and estimate the puck's acceleration if hitting an unprotected zygomatic bone.
82. ** EST A bottle rocket burns for 1.6 s. After it stops burning, it continues moving up to a maximum height of 80 m above the place where it stopped burning. Estimate the acceleration of the rocket during launch. Indicate any assumptions made during your solution. Examine their effect.
83. * **Data from state driver's manual** The state driver's manual lists the reaction distances, braking distances, and total stopping distances for automobiles traveling at different initial speeds (Table 2.11). Use the data to determine the driver's reaction time interval and the acceleration of the automobile while braking. The numbers assume dry surfaces for passenger vehicles.

TABLE 2.11 Data from driver's manual

Speed (mi/h)	Reaction distance (m)	Braking distance (m)	Total stopping distance (m)
20	7	7	14
40	13	32	45
60	20	91	111

84. ** EST Estimate the time interval needed to pass a semi-trailer truck on a highway. If you are on a two-lane highway, how far away from you must an approaching car be in order for you to safely pass the truck without colliding with the oncoming traffic? Indicate any assumptions used in your estimate.
85. * Car A is heading east at 30 m/s and Car B is heading west at 20 m/s. Suddenly, as they approach each other, they see a one-way bridge ahead. They are 100 m apart when they each apply the brakes. Car A's speed decreases at 7.0 m/s each second and car B decreases at 9.0 m/s each second. Do the cars collide? Provide two solutions: one using equations and one using graphs.

Reading Passage Problems

BIO **Head injuries in sports** A research group at Dartmouth College has developed a Head Impact Telemetry (HIT) System that can be used to collect data about head accelerations during impacts on the playing field. The researchers observed 249,613 impacts from 423 football players at nine colleges and high schools and collected collision data from participants in other sports. The accelerations during most head impacts (>89%) in helmeted sports caused head accelerations less than a magnitude of $400\ m/s^2$. However, a total of 11 concussions were diagnosed in players whose impacts caused accelerations between 600 and 1800 m/s^2, with most of the 11 over $1000\ m/s^2$.

86. Suppose that the magnitude of the head velocity change was 10 m/s. Which time interval for the collision would be closest to producing a possible concussion with an acceleration of $1000\ m/s^2$?
(a) 1 s (b) 0.1 s (c) 10^{-2} s
(d) 10^{-3} s (e) 10^{-4} s
87. Using numbers from the previous problem, which answer is closest to the average speed of the head while stopping?
(a) 50 m/s (b) 10 m/s (c) 5 m/s
(d) 0.5 m/s (e) 0.1 m/s
88. Suppose the average speed while stopping was 4 m/s (not necessarily the correct value) and the collision lasted 0.01 s. Which answer is closest to the head's stopping distance (the distance it moves while stopping)?
(a) 0.04 m (b) 0.4 m (c) 4 m
(d) 0.02 m (e) 0.004 m
89. Use Eq. (2.7) and the numbers from Problem 86 to determine which stopping distance is closest to that which would lead to a $1000\ m/s^2$ head acceleration.
(a) 0.005 m (b) 0.5 m (c) 0.1 m
(d) 0.01 m (e) 0.05 m
90. Choose the changes in the head impacts that would *reduce* the acceleration during the impact.
1. A shorter impact time interval
2. A longer impact time interval
3. A shorter stopping distance
4. A longer stopping distance
5. A smaller initial speed
6. A larger initial speed

(d) 2, 4, 5 (e) 2, 4, 6

Automatic sliding doors The first automatic sliding doors were described by Hero of Alexandria almost 2000 years ago. The doors were moved by hanging containers that were filled with water. Modern sliding doors open or close automatically. They are equipped with sensors that detect the proximity of a person and an electronic circuit that processes the signals from the sensors and drives the electromotor-based system that moves the doors. The sensors typically emit pulses of infrared light or ultrasound and detect the reflected pulses. By measuring the delay between emitted and received pulses, the system can determine the distance to the object from which the pulse was reflected. The whole system must be carefully designed to ensure safe and accurate functioning. Designers of such doors take into account several variables such as typical walking speeds of people and their dimensions.

Let's try to learn more about automatic sliding doors by analyzing the motion of a single-side automatic sliding door when a person is walking through the door. **Figure 2.30** shows the position-versus-time graph of the motion of the edge of the door (marked with a red cross in the photo) from the moment the door starts opening to when the door is closed while a person walks toward and through the door. The doors are adjusted to start opening when a person is 2.0 m away.

FIGURE 2.30

91. How long does it take for the door to fully open?
(a) 1.5 s (b) 3 s (c) 5.5 s (d) 11 s
92. How long does it take for the door to close after it is opened?
(a) 11 s (b) 8 s (c) 5.5 s (d) 3 s
93. A person is walking at constant speed of 1.15 m/s toward and through the sliding door. How far from the door is the person when the door starts closing?
(a) 2.3 m (b) 4.3 m (c) 6.3 m (d) 8.3 m
94. What is the average opening speed of the door?
(a) 0.1 m/s (b) 0.3 m/s (c) 0.6 m/s (d) 3.0 m/s
95. What is the maximum speed of the door?
(a) 0.1 m/s (b) 0.3 m/s (c) 0.6 m/s (d) 3.0 m/s
96. A 50-cm-wide person is walking toward the door. What is the maximum walking speed of the person that will allow her to pass through the door without hitting it (assume the person aims for the opening)?
(a) 0.6 m/s (b) 1.2 m/s (c) 1.7 m/s (d) 2.5 m/s

Newtonian Mechanics

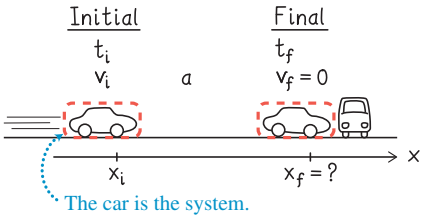
Seat belts and air bags save about 250,000 lives worldwide every year because they significantly reduce the risk of injury (belts alone by about 40% and belts with air bags by about 54%). How do seat belts and air bags provide this protection?

- **How do seat belts and air bags save lives?**
- **If you stand on a bathroom scale in a moving elevator, does its reading change?**
- **Can a parachutist survive a fall if the parachute does not open?**

IN THE LAST CHAPTER, we learned to *describe* motion—for example, to determine a car's acceleration when it stops abruptly during a collision. However, we did not discuss the causes of the acceleration. In this chapter, we will learn *why* an object has a particular acceleration. This knowledge will help us *explain* the motion of many objects: cars, car passengers, elevators, skydivers, and even rockets.

BE SURE YOU KNOW HOW TO:

- Draw a motion diagram for a moving object (Section 2.2).
- Determine the direction of acceleration using a motion diagram (Section 2.7).
- Add vectors graphically and determine their components (Sections 2.3, 2.4, and 2.6).



3.1 Describing and representing interactions

What causes objects to accelerate or maintain a constant velocity? Consider a simple experiment—standing on Rollerblades on a horizontal floor. No matter how hard you swing your arms or legs you cannot start moving by yourself; you need to either push off the floor or have someone push or pull you. Physicists say that the floor or the other person *interacts* with you, thus changing your motion. Objects can interact directly, when they touch each other, or at a distance, as when a magnet attracts or repels another magnet without touching it.

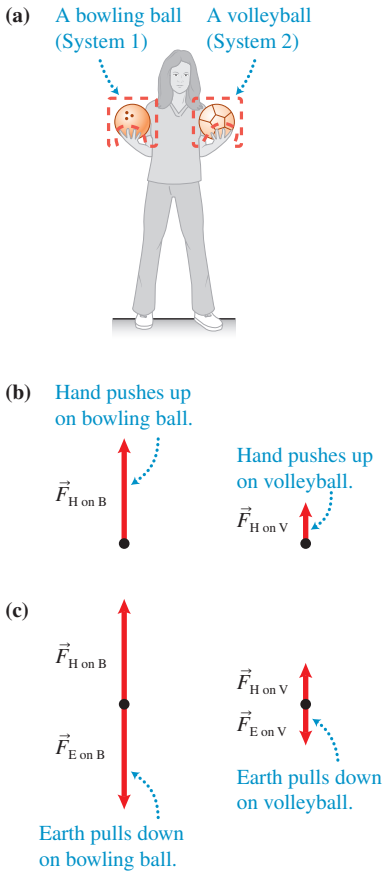
Choosing a system in a sketch of a process

We learned (in Chapter 2) that the first step in analyzing any process is sketching it. **Figure 3.1** shows a sketch of a car skidding to avoid a collision with a van. In this and later chapters we choose one particular object for detailed analysis. We call this object the **system**. All other objects that are not part of the system can interact with it (touch it, pull it, or push it) and are in the system's **environment**. Interactions between the system and objects in the environment are called **external interactions**.

FIGURE 3.1 A sketch of a car skidding to avoid a collision with a van.

System A system is the object or group of objects that we choose to analyze. Everything outside that system is called its environment and consists of objects that might interact with the system (touch, push, or pull it) and affect its motion through external interactions.

On the sketch, we draw a boundary around the system to emphasize the system choice (shown by the red dashed line around the skidding car in Figure 3.1). Sometimes, a single system object has parts—like the wheels on the car and its axles. The parts interact with each other. Since both parts are in the system, these are called **internal interactions**. In this chapter we will model an object like a car as a point-like object and ignore such internal interactions.



Representing interactions

External interactions affect the motion or lack of motion of a system. Consider holding a bowling ball in one hand and a volleyball in the other. Each ball is considered as a system (**Figure 3.2a**). What objects interact with each ball? Your hand pushes up hard to keep the bowling ball steady and much less hard to keep the volleyball steady (Figure 3.2b). We use an arrow to represent the upward push exerted by each hand on one of the balls. Notice that the arrow for the interaction of the hand with the bowling ball is longer than that for the hand with the volleyball.

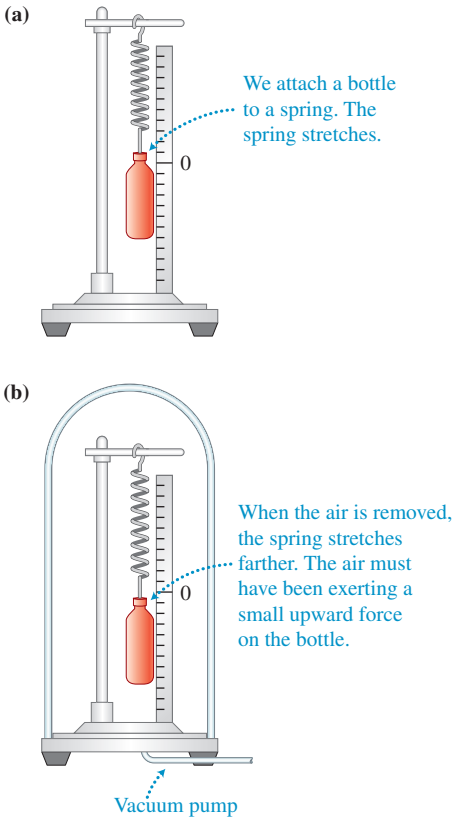
The arrow represents a "force" that is exerted by the hand on the ball. **A force is a physical quantity that characterizes how hard and in what direction an external object pushes or pulls on the system.** The symbol for force is $\vec{F}$ with a subscript that identifies both the external object that exerts the force and the system on which the force is exerted. For example, the hand pushing on the bowling ball is represented as $\vec{F}_{\text{H on B}}$. The force that the hand exerts on the volleyball is $\vec{F}_{\text{H on V}}$. The arrow above the symbol indicates that force is a vector quantity with a magnitude *and* direction. The SI unit of a force is the *newton* (N). When you hold a 100-g ball, you exert an upward force that is a little less than 1.0 N.

Do any other objects exert forces on the balls? Intuitively, we know that something must be pulling down to balance the upward force your hands exert on the balls. The concept of **gravity** represents the interaction of planet Earth with the ball. Earth pulls

FIGURE 3.2 Representing external interactions (forces exerted on a system).

downward on an object toward Earth's center. Because of this interaction we need to include a second arrow representing the force that Earth exerts on the ball $\vec{F}_{\text{E on B}}$ (see Figure 3.2c). Intuitively, we know that the two arrows for each ball should be of the same length, since the balls are not moving.

Do other objects besides the hands and Earth interact with the balls? Air surrounds everything close to Earth. Does it push down or up on the balls? Let's hypothesize that air pushes down. If so, then our hands have to push up harder on the balls to balance the combined effect of the downward push of the air and the downward pull of Earth. Let's test the hypothesis that air pushes down on the balls.



Testing a hypothesis

To test a hypothesis in science means to first accept it as a true statement (even if we disagree with it); then design an experiment whose outcome we can predict using this hypothesis (a testing experiment); then compare the outcome of the experiment and the prediction; and, finally, make a preliminary judgment about the hypothesis. If the outcome matches the prediction, we can say that the hypothesis has not been disproved by the experiment. When this happens, our confidence in the hypothesis increases. If the outcome and prediction are inconsistent, we need to reconsider the hypothesis and possibly reject it.

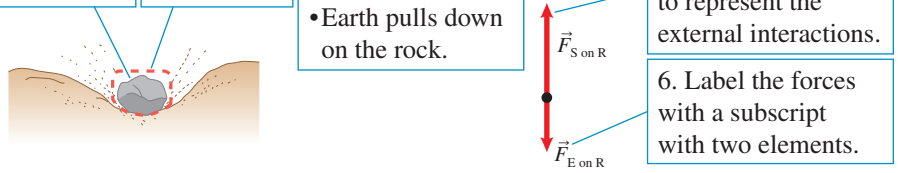
To test the hypothesis that air exerts a downward force on objects, we attach an empty closed water bottle to a spring and let it hang; the spring stretches (**Figure 3.3a**). Next we place the bottle and spring inside a large jar that is connected to a vacuum pump and pump the air out of the inside of the jar. We predict that *if* the air inside the jar pushes down on the bottle (the hypothesis), *then* when we pump the air out of the jar, it should be easier to support the bottle—the spring should stretch less (the prediction that follows from the hypothesis).

When we do the experiment, the outcome does not match the prediction—the spring actually stretches *slightly more* when the air is pumped out of the jar (Figure 3.3b). Evidently the air does not push down on the bottle; instead, it helps support the bottle by exerting an upward force on it. This outcome is surprising. If you study fluids, you will learn the mechanism by which air pushes up on objects.

FIGURE 3.3 A testing experiment to determine the effect of air on the bottle.

Reflect

Let's reflect on what we have done here. We formulated an initial hypothesis—air *pushes down* on objects. Then we designed an experiment whose outcome we could predict using the hypothesis—the bottle on a spring in a vacuum jar. We used the hypothesis to make a prediction of the outcome of the testing experiment—the spring should stretch less in a vacuum. We then performed the experiment and found that something completely different happened. We revised our hypothesis—air *pushes up slightly* on objects. Note that air's upward push on the bottle is very small. Therefore, in many situations, and in all situations in this chapter, the effects of air can be ignored.



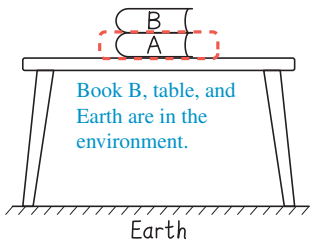
Drawing force diagrams

A **force diagram** (sometimes called a *free-body diagram*) represents the forces that objects in a system's environment exert on it (see Figure 3.2c). We represent the system by a dot to show that we model it as a point-like object. Arrows represent the forces. Unlike a motion diagram, a force diagram does not show us how a process changes with time; it shows us only the forces at a single instant. For processes in which no motion occurs, this makes no difference. But when motion does occur, we need to know if the force diagram is changing as the system moves.

Consider a rock dropped from above and sinking into sand, making a small crater. We construct a force diagram for the instant shortly after the rock touches the sand but before it completely stops moving.

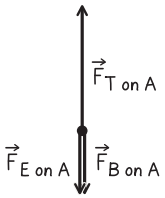
PHYSICS TOOL BOX 3.1 Constructing a force diagram

1. Sketch the situation (a rock sinking into sand).
2. Circle the system (the rock).
3. Identify external interactions:
   - The sand pushes up on the rock.
   - Earth pulls down on the rock.
4. Place a dot at the side of the sketch, representing the system.
5. Draw force arrows to represent the external interactions.
6. Label the forces with a subscript with two elements.



TIP Remember that on the force diagram, you only draw forces exerted *on* the system. Do not draw forces that the system exerts on other objects! For example, the rock exerts a force on the sand, but we do not include this force in the force diagram since the sand is not part of the system.

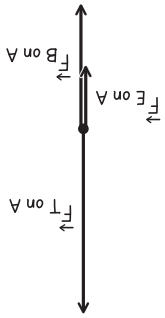
Notice that the upward-pointing arrow representing the force exerted by the sand on the rock is longer than the downward-pointing arrow representing the force exerted by Earth on the rock. The difference in lengths reflects the difference in the magnitudes of the forces.



CONCEPTUAL EXERCISE 3.1 Force diagram for a book

Book A sits on a table with book B on top of it. Construct a force diagram for book A.

Sketch and translate We sketch the situation below. We choose book A as the system. Notice that the dashed line around book A passes between the table and book A, and between book B and book A. It's important to be precise in the way you draw this line so that the separation between the system and the environment is clear. In this example, Earth, the table, and book B are external environmental objects that exert forces on book A.



Simplify and diagram Draw a force diagram for book A, which is represented by a dot. Two objects in the environment touch book A. The table pushes up on the bottom surface of the book, exerting a force $\vec{F}_{\text{T on A}}$, and book B pushes down on the top surface of book A, exerting force $\vec{F}_{\text{B on A}}$. In addition, Earth exerts a downward force on book A $\vec{F}_{\text{E on A}}$. Intuitively, we feel that these forces should somehow cancel each other. The diagram shows this by carefully representing the length of the forces. Note that if you add the two downward forces, their combined length is the same as the upward force. Below we show how to find a resultant force vector when several forces are exerted on an object.

Try it yourself Construct a force diagram for book A after another book C is placed on top of book B.

Answer The same three objects interact with book A. Earth exerts the same downward force on book A ($\vec{F}_{\text{E on A}}$). C does not directly touch A and exerts no force on A. However, C does push down on B, so B exerts a greater force on A ($\vec{F}_{\text{B on A}}$). Because the downward force of B on A is greater, the table exerts a greater upward force on book A ($\vec{F}_{\text{T on A}}$).

Contact and noncontact forces

You can see in the above Conceptual Exercise that some of the forces exerted on book A are exerted by the objects directly touching the book—the table and book B. But Earth does not need to touch the book to exert a force on it. The force that Earth as a whole

planet exerts on every object is an example of a gravitational force. Forces that require the interacting objects to be touching are called **contact forces**, while forces that do not require touching are called **noncontact forces**. The force a rope pulling on a crate exerts (sometimes called a *tension force*) is another example of a contact force; the force of a magnet on another magnet (a magnetic force) is another example of a noncontact force.

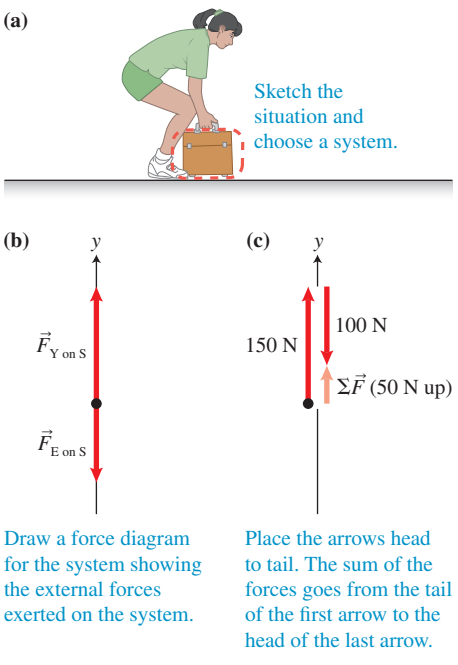
TIP When we write Earth with a capital E and no "the" before it, it means that we are talking about the whole planet, not the surface.

REVIEW QUESTION 3.1 How do we determine how many forces to draw on a force diagram?

3.2 Adding and measuring forces

Usually, more than one environmental object exerts a force on a system. How can we add them to find the total force? In this chapter we will restrict our attention to forces that are exerted and point along one axis. Consider the process of lifting a suitcase.

Adding force vectors graphically



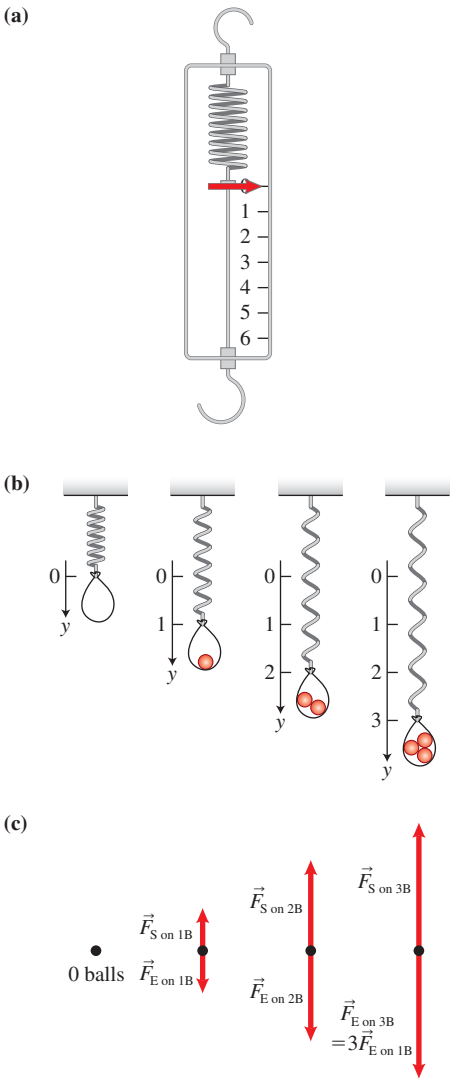
You lift a suitcase straight up (**Figure 3.4a**). Earth pulls down on the suitcase, exerting a force of magnitude $F_{\text{E on S}} = 100\ \text{N}$, and you exert an upward force of magnitude $F_{\text{Y on S}} = 150\ \text{N}$ (Figure 3.4b). What are the magnitude and direction of the total force exerted on the suitcase? The net effect of the two forces exerted along a vertical axis is the same as a 50-N force pointed straight up. Why? Remember that force is a vector. (We discussed the rules for vector addition in Chapter 2.) To add two vectors to find $\Sigma\vec{F} = \vec{F}_{\text{E on S}} + \vec{F}_{\text{Y on S}}$, we place them head to tail (see Figure 3.4c) and draw the vector that goes from the tail of the first vector to the head of the second vector. This new vector is the sum vector, or the resultant vector. In the case of forces it is called the **net force**.

To simplify operations with vectors, we will use components in our calculations. In this chapter we will only analyze situations when all forces are exerted along one axis (x or y) or when forces along one direction add to zero and all the remaining forces are along the other (perpendicular) direction. To find the component of a force along a particular direction, we first need to identify the positive direction, then compare the direction of the force with the identified positive direction. Forces that point in the positive direction of an axis have components equal to their magnitudes; forces that point in the negative direction have components equal to their magnitudes with a negative sign (see Sections 2.4 and 2.6 to review components of a vector). In our example of lifting a suitcase, the y-axis points up. The y-component of the force that you exert on the suitcase is positive and equal to $F_{\text{Y on S}\,y} = 150\ \text{N}$, and the y-component of the force that Earth exerts on the suitcase is $F_{\text{E on S}\,y} = -100\ \text{N}$. The sum of the y-components is $\Sigma F_y = 150\ \text{N} + (-100) = 50\ \text{N}$. This is the y-component of the sum of the forces if the y-axis points up. If the positive direction is down, the sum of the forces has a y-component $\Sigma F_y = -50\ \text{N}$.

If several external objects in the environment exert forces on the system, we still use vector addition to find the *sum* of the forces exerted on the system:

$$\Sigma\vec{F}_{\text{on S}} = \vec{F}_{1\text{ on S}} + \vec{F}_{2\text{ on S}} + \cdots + \vec{F}_{n\text{ on S}} \tag{3.1}$$

FIGURE 3.4 The sum of the forces (the net force) exerted on the suitcase.



TIP The sum of the force vectors is not a new force being exerted. Rather, it is the combined effect of all the forces being exerted on the system. Because of this, the resultant vector should never be included in the force diagram for that system.

Measuring force magnitudes

The simplest device to measure forces is a spring scale (**Figure 3.5a**, on the next page); we will demonstrate this with a simple experiment. Imagine that a light plastic bag hangs from a light spring. The spring is not stretched. We then place one golf ball into the bag and observe that the spring stretches to a new length. We add a second ball and

FIGURE 3.5 Using a spring scale to measure forces.

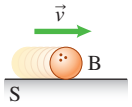
observe that the spring stretches twice as far. We add a third ball and observe that the spring stretches three times as far. Figure 3.5b shows the four situations; for each one, notice the change in the length of the spring. You can see that the spring stretches the same amount for each ball, and that it stretches three times more for three balls than for one ball.

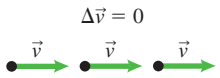
Next, we choose the bag with the golf balls as the system and analyze the forces exerted in each case. We assume that Earth exerts the same force on each ball $\vec{F}_{\text{E on 1B}}$ that is independent of the presence of other balls. Thus, the total force exerted by Earth on the three-ball system is three times greater than the force exerted on the one-ball system. Figure 3.5c shows force diagrams for each case. Because the bag does not fall, the spring in each case must exert a force on the system $\vec{F}_{\text{S on \#B}}$ that is equal in magnitude and opposite in direction to the force that Earth exerts on the system $\vec{F}_{\text{E on \#B}}$ so that the sum of the forces exerted on the system with a number (#) of golf balls is zero.

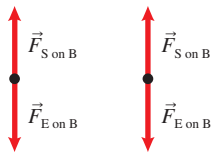
This experiment provides us with one method to measure an unknown force that an object exerts on a system. We calibrate a spring in terms of some standard force, such as Earth's pull on one or more golf balls. Then if some unknown force is exerted on a system, we can use the spring to exert a balancing force on that system. The unknown force is equal in magnitude and opposite in direction to the force exerted by the spring. In this case, we would be measuring force in units equal to Earth's pull on a golf ball. We could use any spring to balance a known standard force (1 N, or approximately the force that Earth exerts on a 100-g object) and then calibrate this spring in newtons by placing marks at equal distances as you pull on its end with increasing force. We thus build a spring scale—the simplest instrument to measure forces.

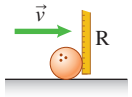
TIP In physics, force is a physical quantity that characterizes the direction and magnitude of an interaction between two objects. **For a force to exist, there must be two objects that interact,** just as a hug requires the interaction of two people. Force does not reside in an object. However, the idea that force resides in an object remains very strong; people say, "The truck's force caused a lot of damage to the telephone pole." We will be careful in this book to always identify the two interacting objects when speaking about any force. Remember, if you are considering a force that is exerted on a moving object but cannot find another object that interacts with it, then you are thinking of something else, not force.

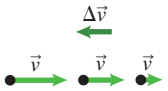
REVIEW QUESTION 3.2 A book bag hanging from a spring scale is partially supported by a platform scale. The platform scale reads about 36 N and the spring scale reads about 28 N. Draw a sketch of the situation, construct a force diagram, and use them to find the magnitude of the force that Earth exerts on the bag.

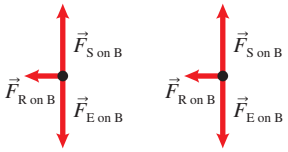


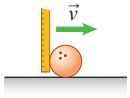


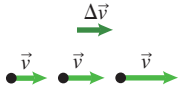


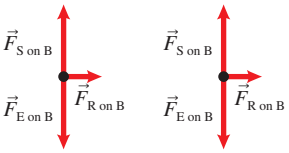












3.3 Conceptual relationship between force and motion

When we drew a force diagram for a ball held by a person, we intuitively drew the forces exerted on the ball as being equal in magnitude. What if the person catches a ball falling from above? Would she still need to exert a force on the ball that has a magnitude equal to that Earth exerts on the ball? In other words, is there a relationship between the forces that are exerted on an object and the way the object moves?

Observational Experiment **Table 3.1** helps us find out whether there is a pattern between the motion diagram and the force diagram for a moving object.

OBSERVATIONAL EXPERIMENT TABLE 3.1 How are motion and forces related?

VIDEO OET 3.1

Observational experiment	Analysis: Motion diagram	Analysis: Force diagrams for first and third positions
Experiment 1. A bowling ball B rolls on a very hard, smooth surface S without slowing down. 		
Experiment 2. A ruler R lightly pushes the rolling bowling ball opposite the ball's direction of motion. The ball continues to move in the same direction, but slows down. 		
Experiment 3. A ruler R lightly pushes the rolling bowling ball in the direction of its motion. The ball speeds up. 		

Pattern

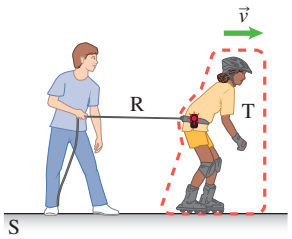
- In all the experiments, the vertical forces add to zero and cancel each other. We consider only forces exerted on the ball in the horizontal direction.
- In the first experiment, the sum of the forces exerted on the ball is zero; the ball's velocity remains constant.
- In the second and third experiments, when the ruler pushes the ball, the velocity change arrow ($\Delta\vec{v}$ arrow) points in the same direction as the sum of the forces.

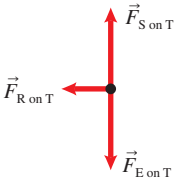
Summary: The $\Delta\vec{v}$ arrow in all experiments is in the same direction as the sum of the forces. Notice that there is no pattern relating the *direction* of the velocity $\vec{v}$ to the direction of the sum of the forces. In Experiment 2, the velocity and the sum of the forces are in opposite directions, but in Experiment 3, they are in the same direction.

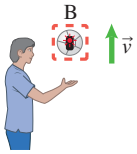
In each of the experiments in Table 3.1, the $\Delta\vec{v}$ arrow for a system and the sum of the forces $\Sigma\vec{F}$ that external objects exert on the system are in the same direction. In addition, we often observe that the $\vec{v}$ arrow for a system (the direction the object is moving) is in the same direction as the sum of the forces exerted on it. For example, a grocery cart moves in the direction the shopper pushes it and a soccer ball moves in the direction the player kicks it. We should test both ideas.

Testing possible relationships between force and motion

We have two possible ideas that relate motion and force:







1. An object's *velocity* $\vec{v}$ always points in the direction of the sum of the forces $\Sigma\vec{F}$ that other objects exert on it.
2. An object's *velocity change* $\Delta\vec{v}$ always points in the direction of the sum of the forces $\Sigma\vec{F}$ that other objects exert on it.

To test these two relationships, we use each to predict the outcome of the experiments in Testing Experiment **Table 3.2**. Then we perform the experiments and compare the outcomes with the predictions. From this comparison, we determine whether we can reject one or both of the relationships.

TESTING EXPERIMENT TABLE 3.2

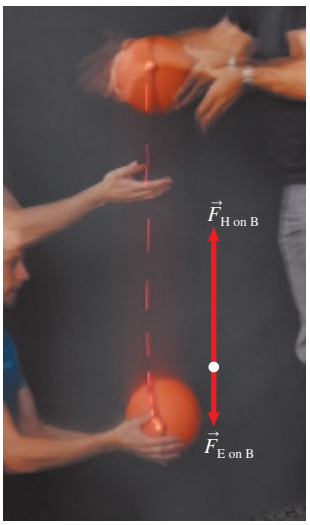
Testing velocity and the sum of the forces $\Sigma\vec{F}$

Testing experiment	Prediction	Outcome
Experiment 1. Tanya, wearing a blinking LED on her belt, coasts to the right on Rollerblades. Her friend pulls her back lightly on a rope. If you took a long-exposure photo of Tanya moving, predict what the LED traces will look like after her friend starts pulling the rope.  	**Prediction based on idea 1:** The sum of the forces exerted on Tanya points to the left. Thus Tanya's velocity should immediately change from right to left. The LED traces should reverse direction the moment her friend starts pulling back.  **Prediction based on idea 2:** Because the sum of the forces points toward the left, the $\Delta\vec{v}$ arrow should point left. Tanya should continue moving to the right, slowing down until she stops. The traces should continue in the same direction as before, only they should get shorter and shorter.	Tanya slows down and eventually stops. The traces are shown below. 
Experiment 2. You throw a ball (with an attached LED) upward. If you took a long-exposure photo of the moving ball, predict what the LED traces will look like.  	**Prediction based on idea 1:** The only force exerted on the ball in flight points down. Thus the ball should immediately begin moving downward after you release it. The LED traces should not appear above the height at which the ball was released.  **Prediction based on idea 2:** Because the only force exerted on the ball in flight points down, the $\Delta\vec{v}$ arrow should point down, too. The ball should slow down until it stops, and then it will start speeding up moving down. The traces continue upward but will become shorter until the ball stops. Then they increase in length in the opposite direction.	The ball moves up at decreasing speed and then reverses direction and starts moving downward. The LED traces are shown at right. 

Conclusion

- All outcomes contradict the predictions based on idea 1—we can reject it.
- All outcomes are consistent with the predictions based on idea 2. This does not necessarily mean it is true, but it does mean our confidence in the idea increases.

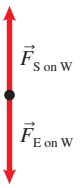
Recall that the $\Delta\vec{v}$ arrow in a motion diagram is in the same direction as the object's acceleration $\vec{a}$. Thus, based on this idea and these testing experiments, we can now accept idea 2 with greater confidence.



Relating forces and motion The velocity change ($\Delta\vec{v}$) arrow in an object's motion diagram (and its acceleration $\vec{a}$) point in the same direction as the sum of the forces that other objects exert on it. If the sum of the forces points in the same direction as the object's velocity, the object speeds up; if the sum points in the opposite direction, it slows down. If the sum of the forces is zero, the object continues with no change in velocity.

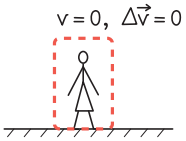
Reflect

How did we devise a relationship that allows us to explain why objects slow down, speed up, or continue at constant velocity? We first observed simple experiments and analyzed them with motion diagrams and force diagrams. We then tested two possible relationships between the objects' motion and the sum of all forces that other objects exerted on it. The above relationship emerged from this analysis and testing.



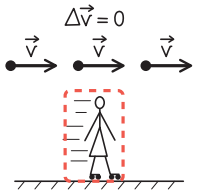
The relationship between forces and change in motion also applies to the situation of catching a dropped ball. **Figure 3.6** shows a ball with an attached blinking LED being dropped and caught and the corresponding force diagram for one instant during the catch.

FIGURE 3.6 Force diagram for a ball being caught.

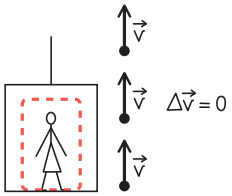


CONCEPTUAL EXERCISE 3.2 **Diagram Jeopardy**

The force diagram shown here describes the forces that external objects (the surface and Earth) exert on a woman (in this scenario, the force diagram does not change with time). Describe three different types of motion of the woman that are consistent with the force diagram.



Sketch and translate Two equal-magnitude, oppositely directed forces are being exerted on the woman ($\Sigma\vec{F} = 0$). Thus, a motion diagram for the woman must have a zero velocity change ($\Delta\vec{v} = 0$).



Simplify and diagram Three possible motions consistent with this idea are shown below.

1. She stands at rest on a horizontal surface.

2. She glides at constant velocity on Rollerblades on a smooth horizontal surface.

3. She stands on the floor of an elevator that moves up or down at constant velocity.

Note that in all three of the above, the velocity change arrow is zero. This is consistent with the sum of the forces being zero.

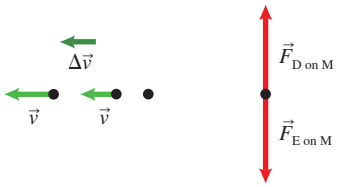
Try it yourself Suppose that the elevator described above was moving up at decreasing speed instead of at constant speed. How then would the force diagram be different?

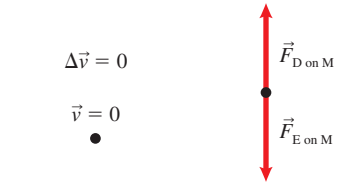
Answer

A velocity change ($\Delta\vec{v}$) arrow for the woman's motion would now point down, opposite the direction of her velocity. Thus, the sum of the forces $\Sigma\vec{F}$ that other objects exert on her must also point down. This means that the magnitude of the upward force $\vec{F}_{\text{S on W}}$ that the elevator floor (surface) exerts on her must now be less than the magnitude of the downward force $\vec{F}_{\text{E on W}}$ that Earth exerts on her ($F_{\text{S on W}} < F_{\text{E on W}}$).

REVIEW QUESTION 3.3 An elevator in a tall office building moves downward at constant speed. How does the magnitude of the upward force exerted by the cable on the elevator $\vec{F}_{\text{C on El}}$ compare to the magnitude of the downward force exerted by Earth on the elevator $\vec{F}_{\text{E on El}}$? Explain your reasoning.

3.4 Inertial reference frames and Newton's first law





Our description of the motion of an object depends on the observer's reference frame. However, in this chapter we have tacitly assumed that all observers were standing on Earth's surface. Are there any observers who will see a chosen object moving with changing velocity even though the sum of the forces exerted on the object appears to be zero?

Inertial reference frames

In **Table 3.3**, we consider two different observers analyzing the same situation.

OBSERVATIONAL EXPERIMENT TABLE 3.3  **Two observers watch the same coffee mug**

VIDEO OET 3.3

Observational experiment	Analysis done by each observer
Experiment 1. Observer 1 is slouched down in the passenger seat of a car and cannot see outside the car. Suddenly, he observes a coffee mug (M) sliding toward him from the dashboard (D).	Observer 1 creates a motion diagram and a force diagram for the mug as he observes it. On the motion diagram, increasingly longer $\vec{v}$ arrows indicate that the mug's speed changes from zero to nonzero as seen by observer 1 even though no external object is exerting a force on it in that direction. 
Experiment 2. Observer 2 stands on the ground beside the car. She observes that the car starts moving forward at increasing speed and that the mug remains stationary with respect to her.	Observer 2 creates a motion diagram and force diagram for the mug as she observes it. There are no $\vec{v}$ or $\Delta\vec{v}$ arrows on the diagram, and the mug is at rest relative to her. 
Pattern	

Observer 1: The forces exerted on the mug by Earth and by the dashboard surface add to zero. But the velocity of the mug increases as it slides off the dashboard. This is inconsistent with the rule relating the sum of the forces and the change in velocity.
Observer 2: The forces exerted on the mug by Earth and by the dashboard surface add to zero. Thus the velocity of the mug should not change, and it does not. This is consistent with the rule relating the sum of the forces and the change in velocity.

VIDEO 3.1

Observer 2 in Table 3.3 can account for what is happening using the rule relating the sum of the forces and changing velocity, but observer 1 cannot. For observer 1, the mug's velocity changes for no apparent reason.

Similarly, in the video in the margin, you see the balls fly inside the box for no reason. For the observer inside the box, Newton's laws cannot explain their behavior. Can you think of some other observers who would be able to explain the balls' motion?

It appears that the applicability of the relationship between the force and motion diagram depends on the reference frame of the observer. Observers who *can* explain the behavior of the mug (observer 2) and the balls by using the relationship between the sum of the forces and changing velocity are said to be observers in **inertial reference frames**. Those who *cannot* explain the behavior of the mug (observer 1) and the balls using this relationship are said to be observers in **noninertial reference frames**. Any observer who accelerates with respect to Earth is a noninertial reference frame observer.

Observers in inertial reference frames can explain the changes in velocity of objects by considering the forces exerted on them by other objects. Observers in noninertial reference frames cannot. From now on, we will always analyze phenomena from the point of view of observers in inertial reference frames. This idea is summarized by Isaac Newton's first law.

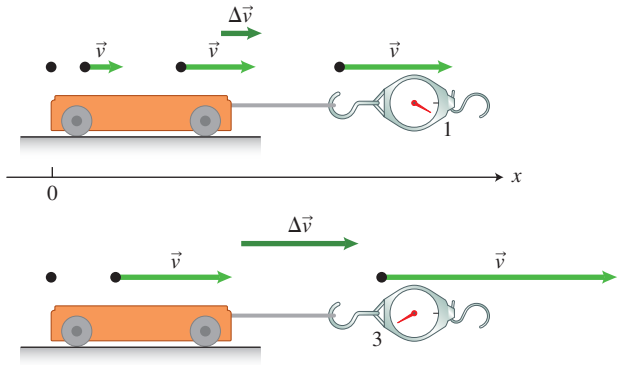
Newton's first law of motion For an observer in an inertial reference frame, when no other objects exert forces on a system or when the forces exerted on the system add to zero, the system continues moving at constant velocity (including remaining at rest).

TIP It is important to note that in physics some mathematical terms and symbols have several different meanings. Zero could mean a balance or an absence. For example, when we say that two forces add to zero, we mean that they balance the effects of each other; when we say an object moves with zero acceleration, we mean that the acceleration is absent. A negative sign in front of a quantity could mean direction or subtraction. Every time you meet a zero or a negative sign, stop and determine how it is being used in that equation.

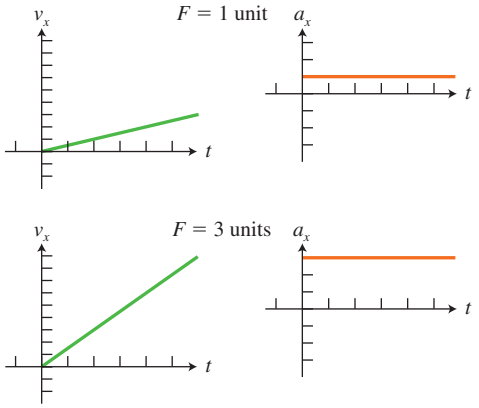
Physicists have analyzed the motion of thousands of objects from the point of view of observers in inertial reference frames and found no contradictions to the rule. Newton's first law of motion limits the reference frames with respect to which the other laws that you will learn in this chapter are valid—these other laws work only for the observers in inertial reference frames. In this and following chapters we will assume that observers of events are not accelerating.

REVIEW QUESTION 3.4 What is the main difference between inertial and noninertial reference frames? Give an example.

Isaac Newton. Isaac Newton (1643–1727) invented differential and integral calculus, formulated the law of universal gravitation, developed a new theory of light, and put together the ideas for his three laws of motion.



3.5 Newton's second law

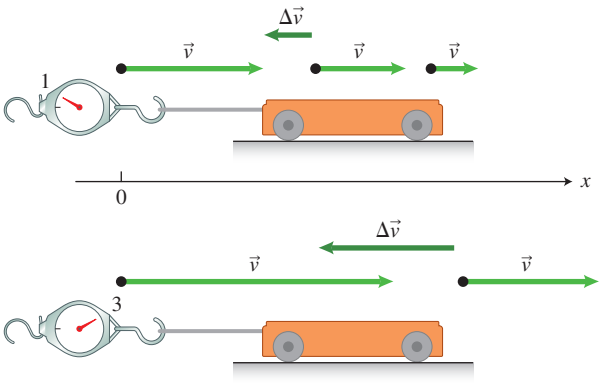


Our conceptual analyses in Section 3.3 allowed us to deduce a qualitative relationship between forces and changes in an object's motion. In this section we will learn how to predict the magnitude of an object's acceleration if we know the forces exerted on it. The experiments in Observational Experiment **Table 3.4** will help us construct this quantitative relationship.

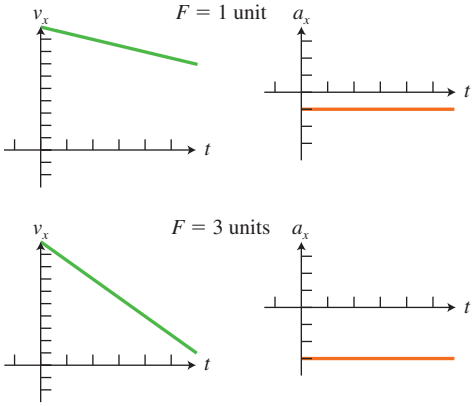
OBSERVATIONAL EXPERIMENT TABLE 3.4 Forces and resulting acceleration

VIDEO OET 3.4

Observational experiment	Analysis
Experiment 1. A cart starts at rest on a smooth horizontal track. A spring scale continuously exerts one unit of force in the positive direction. The experiment is repeated four more times. Each time, the force probe exerts one additional unit of force on the cart (up to three units). We record the value of the force, and use a motion detector on the track to record the cart's speed and acceleration.	Using this information, we create velocity-versus-time and acceleration-versus-time graphs for two of the five different magnitudes of force. Note that the greater the force, the greater the acceleration.

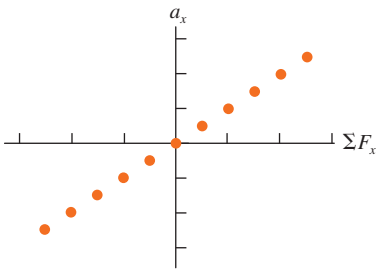


(CONTINUED)



Observational experiment

Experiment 2. We repeat the same five experiments, only this time the cart is moving in the positive direction, and the probe pulls back on the cart in the negative direction so that the cart slows down.



Analysis

We create velocity-versus-time and acceleration-versus-time graphs for the cart when forces of two different magnitudes oppose the cart's motion.

Pattern

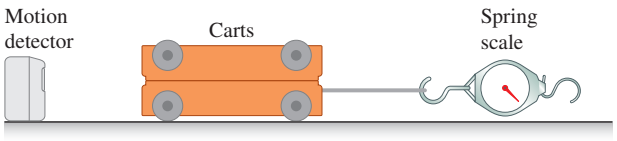
- When the sum of the forces exerted on the cart is constant, its acceleration is constant—the cart's speed increases at a constant rate.
- When we plot acceleration versus force using the five positive and five negative values of the force, we obtain the graph at the right. The eleventh point is (0,0), which we know from previous experiments.
- The acceleration is directly proportional to the force exerted by the spring scale (in this case, it is the sum of all forces) and points in the direction of the force.

The outcome of these experiments expressed mathematically is as follows:

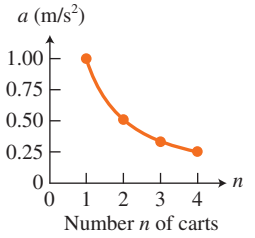
$$\vec{a} \propto \Sigma\vec{F} \tag{3.2}$$

where $\Sigma\vec{F}$ is the sum of all the forces that other objects exert on the system (not an additional force), and $\vec{a}$ is the system's acceleration. The symbol $\propto$ means "is proportional to." In other words, if the sum of the forces doubles, then the acceleration doubles. When the sum of the forces is zero, the acceleration is zero. When the sum of the forces exerted on an object is constant, the object's resulting acceleration (not velocity) is constant.

Mass, another physical quantity

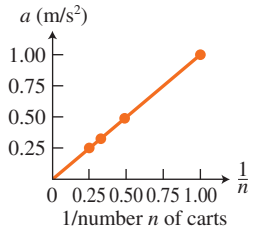


Do other physical quantities affect acceleration? You know from experience that it is easy to pull an empty cardboard box across the floor, but it is much harder when it is full of books. The amount of matter being pulled must affect the acceleration.



Let's perform another experiment to find the quantitative effect of the amount of *matter* being pulled. We use a spring scale to pull one cart, then two carts stacked on top of each other, and then three and four carts on top of each other. In each case, the spring scale exerts the same force on the carts, regardless of how many carts are being pulled. The experiment is summarized in Observational Experiment **Table 3.5**.

OBSERVATIONAL EXPERIMENT TABLE 3.5 Amount of matter and acceleration



Observational experiment	Analysis
We pull the indicated number of stacked carts using an identical pulling force and measure the acceleration with a motion detector.	We graph the acceleration versus number of carts for constant pulling force.

Number n of carts	Acceleration (m/s^2)
1	1.00
2	0.49
3	0.34
4	0.25

From the graph, we see that increasing the number of carts decreases the acceleration. To check whether this relationship is inversely proportional, we plot a versus $\frac{1}{n}$.

Pattern

Since the graph a versus $\frac{1}{n}$ is a straight line, we conclude that a is inversely proportional to n, which we write as $a \propto \frac{1}{n}$.

From the pattern observed in Table 3.5, we conclude that *the greater the amount of matter being pulled, the smaller the object's acceleration when the same force is exerted on it.* This property of an object, which affects its acceleration, is called **mass**.

To measure the mass of an object quantitatively, we first define a standard unit of mass. The choice for the unit of mass is arbitrary, but after the unit has been chosen, the masses of all other objects can be determined from this unit. The SI standard of mass is the kilogram (kg). A quart of milk has a mass of about 1 kg. Suppose, for example, that you exert a constant pulling force on a 1.0-kg object (and that all other forces exerted on this object add to zero), and you measure its acceleration. You then exert the same pulling force on another object of unknown mass. Your measurement indicates that it has half the acceleration of the standard 1.0-kg object. Thus, its mass is twice the standard mass (2.0 kg). This method is not practical for everyday use. Later we will learn another method of measuring the mass of an object, a method that is simple enough to use in everyday life.

Our experiments indicate that when the same force is exerted on two objects, the one with the greater mass will have a smaller acceleration. Mathematically:

$$a \propto \frac{1}{m} \tag{3.3}$$

Mass Mass m characterizes the amount of matter in an object. When the same unbalanced force is exerted on two objects, the object with greater mass has a smaller acceleration. The SI unit of mass is the kilogram (kg). Mass is a scalar quantity, and masses add as scalars.

Sum of the forces, mass and acceleration

We have found that the acceleration $\vec{a}$ of a system is proportional to the vector sum of the forces $\Sigma\vec{F}$ exerted on it by other objects [Eq. (3.2)] and inversely proportional to the mass m of the system [Eq. (3.3)]. We can combine these two proportionalities into a single equation on the next page.

$$\vec{a}_S \propto \frac{\Sigma \vec{F}_{\text{on S}}}{m_S} \tag{3.4}$$

Rearrange the above to get $m_S \vec{a}_S \propto \Sigma \vec{F}_{\text{on S}}$. We can turn this into an equation if we choose the unit of force to be $\text{kg} \cdot \text{m/s}^2$. Because force is such a ubiquitous quantity, physicists have given the force unit a special name called a **newton** (N). A force of 1 newton (1 N) causes an object with a mass of 1 kg to accelerate at $1\ \text{m/s}^2$.

$$1\ \text{N} = 1\ \text{kg} \cdot \text{m/s}^2 \tag{3.5}$$

TIP A force of one pound can also be defined (1 lb equals 4.45 N). When the sum of the forces exerted on an object of a unit of mass (called a slug in the Imperial system of units) is equal to 1 lb, the acceleration of the object is 1 foot/s^2. A slug is a relatively massive unit: 1 slug = 14.95 kg.

Equation (3.4), rewritten with an equality sign instead of a proportional sign, is called **Newton's second law**.

Newton's second law The acceleration $\vec{a}_S$ of a system is proportional to the vector sum of all forces being exerted on the system and inversely proportional to the mass m of the system:

$$\vec{a}_S = \frac{\Sigma \vec{F}_{\text{on S}}}{m_S} = \frac{\vec{F}_{1\text{ on S}} + \vec{F}_{2\text{ on S}} + \cdots}{m_S} \tag{3.6}$$

Here the subscripts 1 and 2 stand for the objects exerting forces on the system.

The acceleration of the system points in the same direction as the vector sum of the forces.

TIP Notice that the "vector sum of the forces" mentioned in the definition at right does not mean the sum of their magnitudes. Vectors are not added as numbers; their directions affect the magnitude of the vector sum.

Does this new equation make sense? For example, does it work in extreme cases? First, imagine an object with an infinitely large mass. According to the law, it will have zero acceleration for any process in which the sum of the forces exerted on it is finite:

$$\vec{a}_S = \frac{\Sigma \vec{F}_{\text{on S}}}{\infty} = 0$$

This seems reasonable, as an infinitely massive object would not change motion due to finite forces exerted on it. On the other hand, an object with a zero mass will have an infinitely large acceleration when a finite magnitude force is exerted on it:

$$\vec{a}_S = \frac{\Sigma \vec{F}_{\text{on S}}}{0} = \infty$$

TIP In the cause-effect relationship, the quantities on the right side of the equation can be varied independently. In our case, these are the sum of the forces and the mass. Each can be changed independently of the other to affect acceleration. In the operational definition, the quantities on the right side of the equation cannot be varied independently. The velocity change depends on the time interval during which it occurs.

Both extreme cases make sense. Newton's second law is a so-called *cause-effect relationship*. The right side of the equation (the sum of the forces being exerted divided by the mass of the system) is the cause of the effect (the acceleration) on the left side.

$$\underset{\text{Effect}}{\vec{a}_S} = \frac{\underset{\text{Cause}}{\Sigma \vec{F}_{\text{on S}}}}{m_S}$$

On the other hand, $\vec{a} = \Delta\vec{v}/\Delta t$ is called an *operational definition* of acceleration. It tells us how to determine the quantity acceleration but does not tell us *why* it has a particular value. For example, suppose that an elevator's speed changes from 2 m/s to 5 m/s in 3 s as it moves vertically along a straight line in the positive y-direction. The elevator's acceleration (using the definition of acceleration) is

$$a_y = \frac{5\ \text{m/s} - 2\ \text{m/s}}{3\ \text{s}} = +1\ \text{m/s}^2$$

This operational definition does not tell you the reason for the acceleration. If you know that the mass of the elevator is 500 kg and that Earth exerts a 5000-N downward

force on the accelerating elevator and the cable exerts a 5500-N upward force on it, then using the cause-effect relationship of Newton's second law:

$$\frac{5500\ \text{N} + (-5000\ \text{N})}{500\ \text{kg}} = +1\ \text{m/s}^2$$

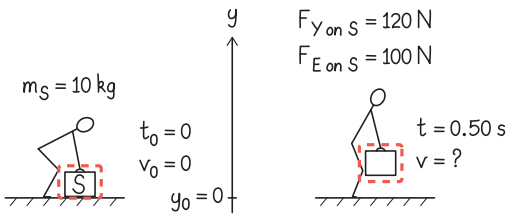
Thus, you obtain the same number using two different methods—one from kinematics (the part of physics that *describes* motion) and the other from dynamics (the part of physics that *explains* motion).

Force components used for forces along one axis

You can use the component form of Newton's second law for the x- and y-directions instead of the vector equation [Eq. (3.6)]:

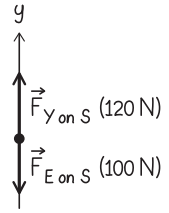
$$a_{Sx} = \frac{\Sigma F_{\text{on S}\,x}}{m_S} \tag{3.7x}$$

and



$$a_{Sy} = \frac{\Sigma F_{\text{on S}\,y}}{m_S} \tag{3.7y}$$

The next example shows you how to apply Newton's second law in component form to solve problems.



EXAMPLE 3.3 Lifting a suitcase

Earth exerts an approximately 100-N force on a 10-kg suitcase. Suppose you exert an upward 120-N force on the suitcase. If the suitcase starts at rest, how fast is it traveling after lifting for 0.50 s?

Sketch and translate First, we sketch the initial and final states of the process, choosing the suitcase as the system. The sketch helps us visualize the process and also brings together all the known information, letting our brains focus on other aspects of solving the problem. One common aspect of problems like this is the use of a two-step strategy. Here, we use Newton's second law to determine the acceleration of the suitcase and then use kinematics to determine the suitcase's speed after lifting for 0.50 s.

Simplify and diagram Next, we construct a force diagram for the suitcase while being lifted. The y-components of the forces exerted on the suitcase are your upward pull on the suitcase $F_{Y\text{ on S}\,y} = +F_{Y\text{ on S}} = +120$ N and Earth's downward pull on the suitcase $F_{E\text{ on S}\,y} = -F_{E\text{ on S}} = -100$ N. Because the upward force is larger, the suitcase will have an upward acceleration $\vec{a}$.

Represent mathematically Since all the forces are along the y-axis, we apply the y-component form of Newton's second law to determine the suitcase's acceleration (notice how the subscripts in the equation below change from step to step):

$$a_{Sy} = \frac{\Sigma F_{\text{on S}\,y}}{m_S} = \frac{F_{Y\text{ on S}\,y} + F_{E\text{ on S}\,y}}{m_S}$$

$$= \frac{(+F_{Y\text{ on S}}) + (-F_{E\text{ on S}})}{m_S} = \frac{F_{Y\text{ on S}} - F_{E\text{ on S}}}{m_S}$$

After using Newton's second law to determine the acceleration of the suitcase, we then use kinematics to determine the suitcase's speed after traveling upward for 0.50 s:

$$v_y = v_{0y} + a_y t$$

The initial velocity is $v_{0y} = 0$.

Solve and evaluate Now substitute the known information in the Newton's second law y-component equation above to find the acceleration of the suitcase:

$$a_{Sy} = \frac{F_{Y\text{ on S}} - F_{E\text{ on S}}}{m_S} = \frac{120\ \text{N} - 100\ \text{N}}{10\ \text{kg}} = +2.0\ \text{m/s}^2$$

Insert this and other known information into the kinematics equation to find the vertical velocity of the suitcase after lifting for 0.50 s:

$$v_y = v_{0y} + a_y t = 0 + (+2.0\ \text{m/s}^2)(0.50\ \text{s}) = +1.0\ \text{m/s}$$

The unit for time is correct and the magnitude is reasonable.

Try it yourself How far up did you pull the suitcase during this 0.50 s?

Answer The average speed while lifting it was $(0 + 1.0\ \text{m/s})/2 = 0.50\ \text{m/s}$. Thus you lifted the suitcase $y - y_0 = (0.50\ \text{m/s})(0.50\ \text{s}) = 0.25\ \text{m}$.

REVIEW QUESTION 3.5 Your friend says that $m\vec{a}$ is a force exerted on an object and it should be represented on the force diagram. Do you agree or disagree with him? Explain your answer.

3.6 Gravitational force law

In the last example, we were given the mass of a suitcase (10 kg) and the approximate magnitude of the gravitational force that Earth exerts on it (100 N). Is it possible to determine the magnitude of this force by just knowing the mass of the suitcase?

Imagine that we evacuate all the air from a 3.0-m-long Plexiglas tube, place a motion sensor at the top, and drop objects of various sizes, shapes, and compositions through the tube (as was done with a feather and an apple in Figure 2.26). The measurements taken by the motion sensor reveal that all objects fall straight down with the same acceleration, approximately 9.8 $\mathrm{m/s^2}$. Earth is the only object that exerts the force on the falling object $\vec{F}_{\mathrm{E\ on\ O}}$ during the entire flight. If we choose the positive y-axis pointing down and apply the y-component form of Newton's second law, we get

$$a_{\mathrm{O}y} = \frac{1}{m_{\mathrm{O}}} F_{\mathrm{E\ on\ O}\,y} = \frac{1}{m_{\mathrm{O}}}(+F_{\mathrm{E\ on\ O}}) = +\frac{F_{\mathrm{E\ on\ O}}}{m_{\mathrm{O}}}$$

Every object dropped in our experiment had the same free-fall acceleration, $g = 9.8\ \mathrm{m/s^2}$, even those with very different masses (such as a ping-pong ball and a lead ball). Thus, the gravitational force that Earth exerts on each object must be proportional to its mass so that the mass cancels when we calculate the acceleration. Earth must exert a force on a 10-kg object that is 10 times greater than that on a 1-kg object:

$$a_{\mathrm{O}y} = \frac{F_{\mathrm{E\ on\ O}}}{m_{\mathrm{O}}} = g$$

This reasoning leaves just one possibility for the magnitude of the force that Earth exerts on an object:

$$F_{\mathrm{E\ on\ O}} = m_{\mathrm{O}} g = m_{\mathrm{O}}(9.8\ \mathrm{m/s^2})$$

The ratio of the force and the mass is a constant for all objects—the so-called gravitational coefficient g, already familiar to us as free-fall acceleration.

Gravitational force The magnitude of the gravitational force that Earth exerts on any object $F_{\mathrm{E\ on\ O}}$ when on or near its surface equals the product of the object's mass m and the coefficient g:

$$F_{\mathrm{E\ on\ O}} = m_{\mathrm{O}} g \tag{3.8}$$

where $g = 9.8\ \mathrm{m/s^2} = 9.8\ \mathrm{N/kg}$ on or near Earth's surface. This force points toward the center of Earth.

TIP Equation (3.8) is a cause-effect relation because m_{O} and g can be varied independently.

The value of the free-fall acceleration g in the above gravitational force relation [Eq. (3.8)] does not mean that the object is actually falling. The g is just used to determine the magnitude of the gravitational force exerted on the object by Earth whether the object is falling, sitting at rest on a table, or moving down a waterslide. To avoid confusion, we will use $g = 9.8\ \mathrm{N/kg}$ rather than 9.8 $\mathrm{m/s^2}$ when calculating the gravitational force. Sometimes, when we do not need high precision in the calculation, we will even use 10 $\mathrm{N/kg}$.

We will learn in the chapter on circular motion (Chapter 5) that the gravitational coefficient g at a particular point depends on the mass of Earth and on how far this

point is from the center of Earth. On Mars or the Moon, the gravitational coefficient depends on the mass of Mars or the Moon, respectively. The gravitational coefficient is 1.6 N/kg on the Moon and 3.7 N/kg on Mars. You could throw a ball upward higher on the Moon since g is smaller there, resulting in a smaller force exerted downward on the ball.

TIP The *weight* of an object on a planet is the force that the planet exerts on the object. We will not use the term "weight of an object" because it implies that weight is a property of the object rather than an interaction between two objects.

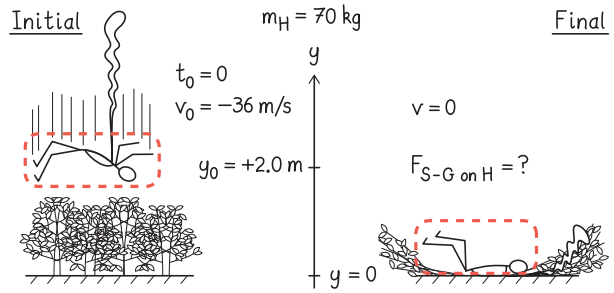
REVIEW QUESTION 3.6 Newton's second law says that the acceleration of an object is inversely proportional to its mass. However, the acceleration with which all objects fall in the absence of air is the same. How can this be?

3.7 Skills for applying Newton's second law for one-dimensional processes

In this section we will develop a strategy that can be used whenever a process involves force and motion. We will introduce the strategy by applying it to the 2006 skydive of diving champion Michael Holmes. After more than 7000 successful jumps, Holmes jumped from an airplane 3700 m above Lake Taupo in New Zealand. His main parachute failed to open, and his backup chute became tangled in its cords. The partially opened backup parachute slowed his descent to about 36 m/s (80 mi/h) as he reached a 2-m-high thicket of wild shrubbery. Holmes survived.

TIP In all problems, unless specifically noted, we will assume that the observer is on the ground and is not accelerating.

PROBLEM-SOLVING STRATEGY 3.1 Applying Newton's laws for one-dimensional processes



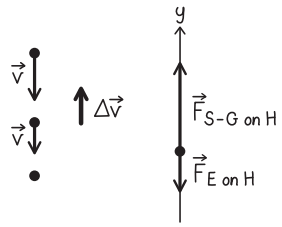
Sketch and translate

- Sketch the process.
- Choose the system.
- Choose a coordinate system.
- Label the sketch with everything you know about the situation.
- Identify the unknown that you need to find. Label it with a question mark on the sketch.

EXAMPLE 3.4 Holmes's skydive

Michael Holmes (70 kg) was moving downward at 36 m/s (80 mi/h) and was stopped by 2.0-m-high shrubbery and the ground. Estimate the average force exerted by the shrubbery and ground on his body while stopping his fall.

We sketch the process, choosing Holmes as the system (H). We want to know the average force that the shrubbery and ground (S-G) exert on him from when he first touches the shrubbery to the instant when he stops. We choose the y-axis pointing up and the origin at the ground where Holmes comes to rest. We use kinematics to find his acceleration while stopping and Newton's second law to find the average force that the shrubbery and ground exerted on him while stopping him.



(CONTINUED)

Simplify and diagram

- Make appropriate simplifying assumptions about the process. For example, can you neglect the size of the system? Can you assume that forces or acceleration is constant?
- Then represent the process with a motion diagram and/or force diagram(s). Make sure the diagrams are consistent with each other.

We model Holmes as a point-like object and assume that the forces being exerted on him are constant so that they lead to a constant acceleration. A motion diagram for his motion while stopping is shown along with the corresponding force diagram. To draw the force diagram we first identify the objects interacting with Holmes as he slows down: the shrubbery and ground (combined as one interaction) and Earth. The shrubbery and ground exert an upward force $\vec{F}_{\text{S-G on H}}$ on Holmes. Earth exerts a downward gravitational force $\vec{F}_{\text{E on H}}$. The force diagram is the same for all points of the motion diagram because the acceleration is constant. On the force diagram the arrow for $\vec{F}_{\text{S-G on H}}$ must be longer to match the motion diagram, which shows the velocity change arrow pointing up.

Represent mathematically

- Convert these qualitative representations into quantitative mathematical descriptions of the situation using kinematics equations and Newton's second law for motion along the axis. Determine the signs for the force components in the equations. Add the force components (with either positive or negative signs) to find the sum of the forces.

The y-component of Holmes's average acceleration is

$$a_y = \frac{v_y^2 - v_{0y}^2}{2(y - y_0)}$$

The y-component of Newton's second law with the positive y-direction up is

$$a_y = \frac{\Sigma F_{\text{on H}\,y}}{m_{\text{H}}}$$

The y-component of the force exerted by the shrubbery-ground on Holmes is $F_{\text{S-G on H}\,y} = +F_{\text{S-G on H}}$, and the y-component of the force exerted by Earth is $F_{\text{E on H}\,y} = -F_{\text{E on H}} = -m_{\text{H}}g$. Therefore,

$$a_y = \frac{F_{\text{S-G on H}\,y} + F_{\text{E on H}\,y}}{m_{\text{H}}} = \frac{(+F_{\text{S-G on H}}) + (-F_{\text{E on H}})}{m_{\text{H}}} = \frac{+F_{\text{S-G on H}} - m_{\text{H}}g}{m_{\text{H}}}$$

$$\Rightarrow F_{\text{S-G on H}} = m_{\text{H}}a_y + m_{\text{H}}g$$

Solve and evaluate

- Substitute the known values into the mathematical expressions and solve for the unknowns.
- Finally, evaluate your work to see if it is reasonable (check units, limiting cases, and whether the answer has a reasonable magnitude). Check whether all representations—mathematical, pictorial, and graphical—are consistent with each other.

Holmes's average acceleration was

$$a_y = \frac{0^2 - (-36\ \text{m/s})^2}{2(0 - 2.0\ \text{m})} = +324\ \text{m/s}^2$$

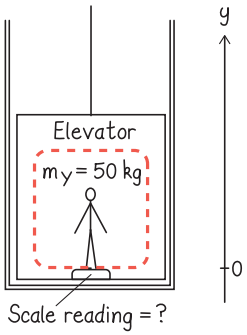
Holmes's initial velocity is negative, since he is moving in the negative direction. His initial position is +2.0 m at the top of the shrubbery, and his final position is zero at the ground. His velocity in the negative direction is decreasing, which means the velocity change and the acceleration both point in the opposite direction (positive). The average magnitude of the force exerted by the shrubbery and ground on Holmes is

$$F_{\text{S-G on H}} = m_{\text{H}}a_y + m_{\text{H}}g = (70\ \text{kg})(324\ \text{m/s}^2) + (70\ \text{kg})(9.8\ \text{N/kg})$$
$$= 22{,}680\ \text{kg}\cdot\text{m/s}^2 + 686\ \text{N} = 23{,}366\ \text{N} = 23{,}000\ \text{N}$$

The force has a magnitude greater than the force exerted by Earth—thus the results are consistent with the force diagram and motion diagram. The magnitude is huge and the units are correct. A limiting case for zero acceleration gives us a correct prediction—the force exerted on Holmes by the shrubbery and ground equals the force exerted by Earth.

Try it yourself What process involving forces can be described by the equation $50\ \text{kg} \times 2\ \text{m/s}^2 = 50\ \text{kg} \times 9.8\ \text{N/kg} + (-390\ \text{N})$?

Answer A 50-kg person is landing on a thick cushion that exerts a 390-N upward force on her but cannot slow her down. She continues to accelerate down, but her acceleration is less than g (only 2 m/s^2). The vertical axis points down.



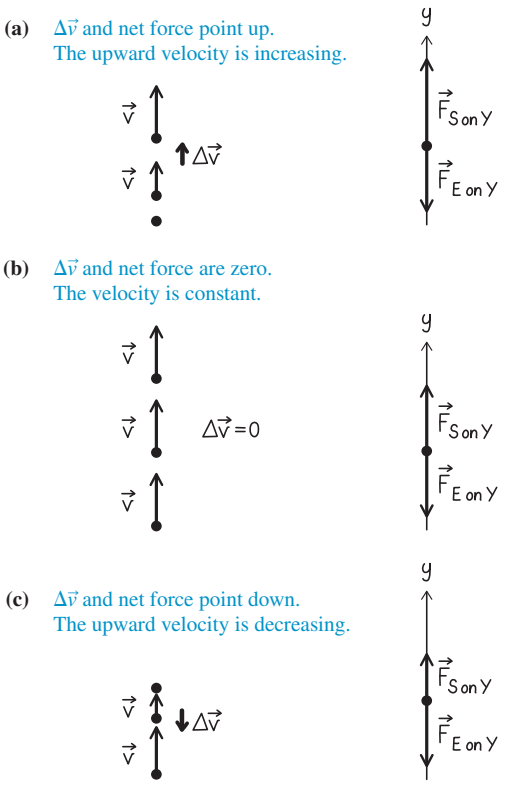
An elevator ride standing on a bathroom scale

In Example 3.5, we consider a much less dangerous process, one you could try the next time you ride an elevator. When you stand on a bathroom scale, the scale reading indicates how hard you are pushing on the scale. The force that it exerts on you balances the downward force that Earth exerts on you, resulting in your zero acceleration. What will the scale read if you stand on it in a moving elevator?

EXAMPLE 3.5 **Elevator ride**

You stand on a bathroom scale in an elevator as it makes a trip from the first floor to the tenth floor of a hotel. Your mass is 50 kg. When you stand on the scale in the stationary elevator, it reads 490 N (110 lb). What will the scale read (a) early in the trip while the elevator's upward acceleration is 1.0 m/s^2, (b) while the elevator moves up at a constant speed of 4.0 m/s, and (c) when the elevator slows to a stop with a downward acceleration of 1.0 m/s^2 magnitude?

Sketch and translate We sketch the situation as shown at right, choosing you as the system. The coordinate axis points upward with its origin at the first floor of the elevator shaft. Your mass is $m_Y = 50$ kg, the magnitude of the force that Earth exerts on you is $F_{E\text{ on }Y} = m_Y g = 490$ N, and your acceleration is (a) $a_y = +1.0$ m/s^2 (the upward velocity is increasing); (b) $a_y = 0$ (v is a constant 4.0 m/s upward); and (c) $a_y = -1.0$ m/s^2 (the upward velocity is decreasing, so the acceleration points in the opposite, negative direction).



Simplify and diagram We model you as a point-like object and represent you as a dot in both the motion and force diagrams, shown for each part of the trip in Figures a, b, and c. On the diagrams, E represents Earth, Y is you, and S is the scale. The magnitude of the downward force that Earth exerts does not change (it equals $m_Y\vec{g}$, and neither m_Y nor $\vec{g}$ changes). Notice that the force diagrams and motion diagrams are consistent with each other for each part of the trip. The length of the arrows representing the force that the scale exerts on you changes from one case to the next so that the sum of the forces points in the same direction as your velocity change arrow.

Represent mathematically The motion and the forces are entirely along the vertical y-axis. Thus, we use the vertical y-component form of Newton's second law [Eq. (3.7y)] to analyze the process. There are two forces exerted on you (the system) so there will be two vertical y-component forces on the right side of the equation: the y-component of the force that Earth exerts on you, $F_{E\text{ on }Y\,y} = -m_Y g$, and the y-component of the force that the scale exerts on you, $F_{S\text{ on }Y\,y} = +F_{S\text{ on }Y}$:

$$a_{Yy} = \frac{\Sigma F_y}{m_Y} = \frac{F_{E\text{ on }Y\,y} + F_{S\text{ on }Y\,y}}{m_Y} = \frac{-m_Y g + F_{S\text{ on }Y}}{m_Y}$$

Multiplying both sides by m_Y, we get $a_{Yy}m_Y = -m_Y g + F_{S\text{ on }Y}$. We can now move $-m_Y g$ to the left side: $m_Y a_{Yy} + m_Y g = F_{S\text{ on }Y}$, or

$$F_{S\text{ on }Y} = m_Y a_{Yy} + m_Y g = m_Y a_{Yy} + 490\text{ N}$$

Remember that $m_Y g = 490$ N is the magnitude of the force that Earth exerts on you. The expression for $F_{S\text{ on }Y}$ gives the magnitude of the force that the scale exerts on you.

Solve and evaluate We can now use the last equation to predict the scale reading for the three parts of the trip.

(a) Early in the trip, the elevator is speeding up, and its acceleration is $a_{Yy} = +1.0$ m/s^2. During that time interval, the force exerted by the scale on you should be

$$F_{S\text{ on }Y} = m_Y a_{Yy} + 490\text{ N}$$
$$= (50\text{ kg})(+1.0\text{ m/s}^2) + 490\text{ N} = 540\text{ N}$$

(b) In the middle of the trip, when the elevator moves at constant velocity, your acceleration is zero and the scale should read

$$F_{S\text{ on }Y} = m_Y a_{Yy} + 490\text{ N}$$
$$= (50\text{ kg})(0\text{ m/s}^2) + 490\text{ N} = 490\text{ N}$$

(CONTINUED)

(c) When the elevator is slowing down near the end of the trip, its acceleration points downward and is $a_y = -1.0\ \text{m/s}^2$. Then the force exerted by the scale on you should be

$$F_{\text{S on Y}} = m_{\text{Y}}\, a_{\text{Y}y} + 490\ \text{N}$$
$$= (50\ \text{kg})(-1.0\ \text{m/s}^2) + 490\ \text{N} = 440\ \text{N}$$

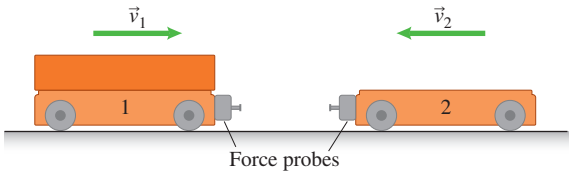
When the elevator is at rest or moving at constant speed, the scale reading equals the magnitude of the force that Earth exerts on you. When the elevator accelerates upward, the scale reads more. When it accelerates downward, even if you are moving upward, the scale reads less. What is also important is that the motion and force diagrams in Figures a, b, and c are consistent with each other and the force diagrams are consistent with the predicted scale readings—an important consistency check of the motion diagrams, force diagrams, and math.

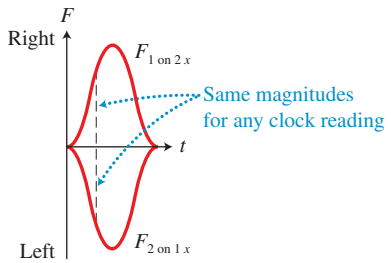
Try it yourself You are standing on the scale in the elevator. The scale first reads 490 N, then 440 N, then 490 N again, and finally 540 N. What could possibly be happening to the elevator?

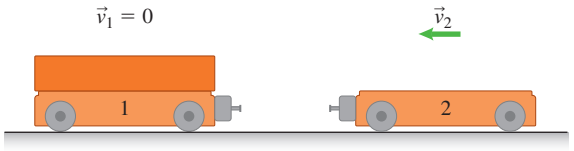
Answer The elevator is at rest, then moves down with downward acceleration of 1 m/s^2, then moves at constant velocity, and finally starts to slow down with acceleration of 1 m/s^2 pointing upward.

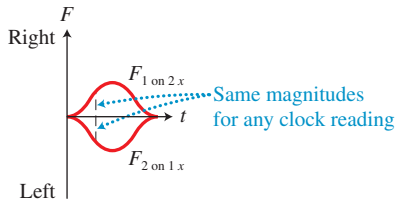
It might not seem very important to know what a scale reads in an elevator as it moves, but if we consider the cable supporting the elevator, the value of such calculations becomes apparent. We deduce that the force that the cable exerts on the elevator when the elevator is accelerating upward is greater than that when the elevator is at rest or moving with constant velocity. This means that the cable must be strong enough to withstand a magnitude of force of at least $mg + ma$, where m is the mass of the elevator and its maximum load, and a is the magnitude of the elevator's maximum vertical acceleration.

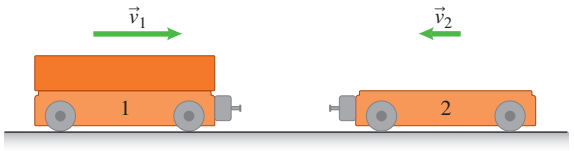
REVIEW QUESTION 3.7 Three friends argue about the type of information a bathroom scale reports: Eugenia says that it reads the force that Earth exerts on a person, Alan says that it reads the sum of the forces exerted on the person by Earth and the scale, and Mike says that the scale reads the force that the person exerts on the scale. Who do you think is correct? Why?

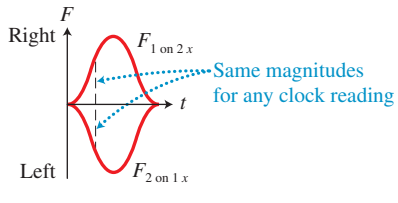












3.8 Forces come in pairs: Newton's third law

So far, we have analyzed a system's acceleration due to the forces exerted on it by external objects. What effect does the system have on these external objects? To help answer this question, we observe the interaction of two objects and analyze what happens to each of them. Suppose, while wearing Rollerblades, you push abruptly on a wheeled cart that is loaded with a heavy box. If you and the cart are on a hard smooth floor, the cart starts to move (it accelerates), and you also start to move and accelerate in the opposite direction. Evidently, you exerted a force on the cart and the cart exerted a force on you. Since the accelerations were in opposite directions, the forces must point in opposite directions. Let's consider more quantitatively the effect of such a mutual interaction between two objects.

Consider the experiments in Observational Experiment **Table 3.6**. Two dynamics carts roll freely on a smooth track before colliding. We mount force probes on each cart in order to measure the forces that each cart exerts on the other while colliding. A motion sensor on each end of the track records the initial velocity of each cart before the collision.

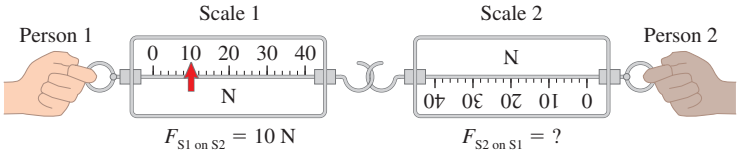
OBSERVATIONAL EXPERIMENT TABLE 3.6 Forces that two dynamics carts exert on each other

VIDEO OET 3.6

Observational experiment	Analysis
Experiment 1. Two carts of different masses move toward each other on a level track. A motion detector indicates their speed before the collision, and force probes record the forces exerted by each cart on the other. Before the collision: $m_1 = 1.0\ \text{kg}, v_{1x} = +2\ \text{m/s}$ $m_2 = 0.5\ \text{kg}, v_{2x} = -2\ \text{m/s}$ 	Because both carts changed velocities due to the collision, they must have exerted forces on each other. The computer recordings from the force probes show that the forces that the carts exert on each other vary with time and at each time have the same magnitude and point in opposite directions. Cart 1 exerts a force on cart 2 toward the right, and cart 2 exerts a force on cart 1 toward the left. 
Experiment 2. Cart masses and velocities before collision: $m_1 = 1.0\ \text{kg}, v_{1x} = 0\ \text{m/s}\ \text{(at rest)}$ $m_2 = 0.5\ \text{kg}, v_{2x} = -1\ \text{m/s}$ 	Although the forces that the carts exert on each other are smaller than in the first experiment, the magnitudes of the forces at each time are still the same. 
Experiment 3. Cart masses and velocities before collision: $m_1 = 1.0\ \text{kg}, v_{1x} = +2\ \text{m/s}$ $m_2 = 0.5\ \text{kg}, v_{2x} = -1\ \text{m/s}$ 	The same analysis applies. 

Pattern

In each experiment, independent of the masses and velocities of the carts before the collisions, at every instant during the collision the force that cart 1 exerted on cart 2 $\vec{F}_{1\text{ on }2}$ had the same magnitude as but pointed in the opposite direction from the force that cart 2 exerted on cart 1 $\vec{F}_{2\text{ on }1}$.



The cart collisions in Table 3.6 indicate that the force that one cart exerts on another is equal in magnitude and opposite in direction to the force that the second cart exerts on the first.

$$\vec{F}_{1\text{ on }2} = -\vec{F}_{2\text{ on }1}$$

Will the pattern that we found allow us to correctly predict the results of a new experiment?

TESTING EXPERIMENT TABLE 3.7 **Testing the relationship between the forces that interacting objects exert on each other**

VIDEO TET 3.7

Testing experiment	Prediction	Outcome
Two people are holding spring scales that are hooked together. The scales remain horizontal during the experiment. Person 1 pulls her scale so that scale 1 reads 10 N, while person 2 just holds scale 2. Predict the reading of scale 2.  Predict the reading of scale 1 when person 2 pulls scale 2 exerting an arbitrary force.	If the pattern relating the two forces that interacting objects exert on each other (they have the same magnitudes and opposite directions) is correct, and scale 1 pulls on scale 2 exerting a force of 10 N, then scale 2 should pull on scale 1 in the opposite direction exerting a force of 10 N. Both scales will have the same reading. The same is true for the readings of the scales when scale 2 pulls on scale 1.	The experiments show that no matter who pulls on a scale, the scales have the same reading.

Conclusion

The outcome supports the pattern in the forces that two objects exert on each other during the interaction. These forces are of the same magnitude and opposite in direction.

To be convinced of the validity of this conclusion, we need many more testing experiments. So far, physicists have found no experiments involving the dynamics of everyday processes in which interacting objects exert forces on each other that are not of equal magnitude and oppositely directed. This relationship between the forces is called **Newton's third law**.

Newton's third law When two objects interact, object 1 exerts a force on object 2. Object 2 in turn exerts an equal-magnitude, oppositely directed force on object 1:

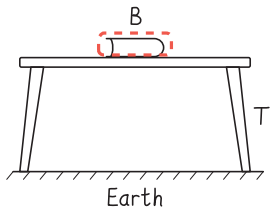
$$\vec{F}_{1 \text{ on } 2} = -\vec{F}_{2 \text{ on } 1} \tag{3.9}$$

Note that these forces are exerted on different objects and *cannot* be added to find the sum of the forces exerted on one object.

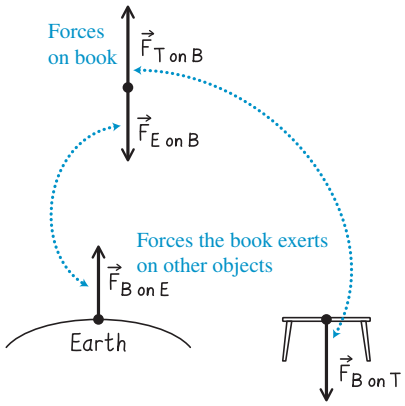
It seems counterintuitive that two interacting objects always exert forces of the same magnitude on each other. Imagine a game of ping-pong. A paddle hits the ball and the ball flies rapidly toward the other side of the table. However, the paddle moves forward with little change in motion. How is it possible that the light ball exerted a force on the paddle of the same magnitude as the force the paddle exerted on the ball?

To resolve this apparent contradiction, think about the masses of the interacting objects and their corresponding accelerations. If the forces are the same, the object with larger mass has a smaller magnitude acceleration than the object with smaller mass:

$$a_{\text{paddle}} = \frac{F_{\text{ball on paddle}}}{m_{\text{paddle}}} \quad \text{and} \quad a_{\text{ball}} = \frac{F_{\text{paddle on ball}}}{m_{\text{ball}}}$$



Because the mass of the ball is so small, the same force leads to a large change in velocity. The paddle's mass, on the other hand, is much larger. Thus, the same magnitude force leads to an almost zero velocity change. We observe the velocity change and incorrectly associate that alone with the force exerted on the object.



TIP Remember that the forces in Newton's third law are exerted on two different objects. This means that the two forces will never show up on the same force diagram, and they should not be added together to find the sum of the forces. You have to choose the system and consider only the forces exerted on *it*!

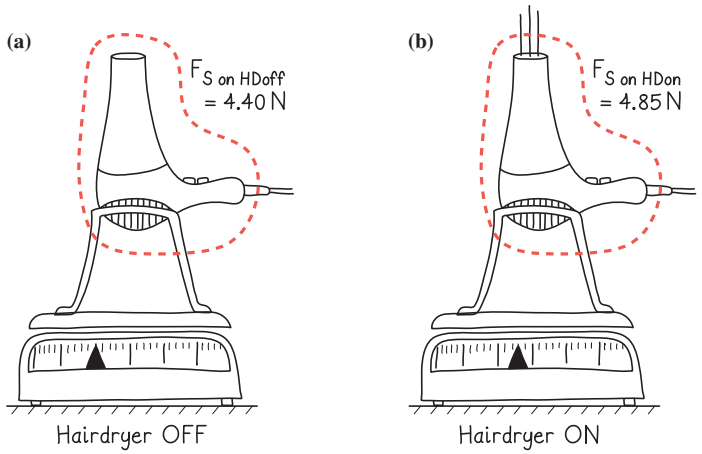
CONCEPTUAL EXERCISE 3.6 A book on a table

A book sits on a tabletop. Identify the forces exerted on the book by other objects. Then, for each of these forces, identify the force that the book exerts on another object. Explain why the book is not accelerating.

Sketch and translate Draw a sketch of the situation and choose the book as the system.

Simplify and diagram Assume that the tabletop is perfectly horizontal and model the book as a point-like object. A force diagram for the book is shown at right. Earth exerts a downward gravitational force on the book $\vec{F}_{E\text{ on }B}$, and the table exerts an upward force on the book $\vec{F}_{T\text{ on }B}$. Newton's second law explains why the book is not accelerating: the forces exerted on it by other objects are balanced and add to zero.

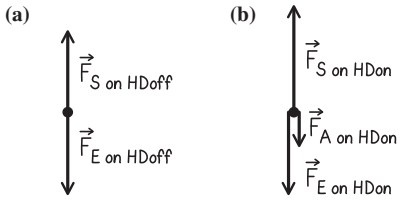
The subscripts on each force identify the two objects involved in the interaction. The Newton's third law pair force will have its subscripts reversed. For example, Earth exerts a downward gravitational force on the book ($\vec{F}_{E\text{ on }B}$). According to Newton's third law, the book must exert an equal-magnitude upward gravitational force on Earth ($\vec{F}_{B\text{ on }E} = -\vec{F}_{E\text{ on }B}$), as shown at right. The table exerts an upward contact force on the book ($\vec{F}_{T\text{ on }B}$), so the book must exert an equal-magnitude downward contact force on the table ($\vec{F}_{B\text{ on }T} = -\vec{F}_{T\text{ on }B}$).



Try it yourself A horse pulls on a sled that is stuck in snow and not moving. Your friend Chris says this happens because the horse exerts on the sled the same magnitude force that the sled exerts on the horse. Since the sum of the forces is zero, there is no acceleration. What is wrong with Chris's reasoning?

Answer Chris added the forces exerted on two different objects and did not consider all forces exerted on the sled. If you choose the sled as the system, then the horse pulls forward on the sled, and the snow exerts a backward, resistive force. If these two horizontal forces happen to be of the same magnitude, they add to zero, and the sled does not accelerate horizontally. If, on the other hand, we choose the horse as the system, the ground exerts a forward force on the horse's hooves (since the horse is exerting a force backward on the ground), and the sled pulls back on the horse. If those forces have the same magnitude, the net horizontal force is again zero, and the horse does not accelerate.

EXAMPLE 3.7 Hairdryer on a scale



Hairdryers contain a small propeller that pushes air away from the dryer through a nozzle. You place a hairdryer on a scale with the nozzle pointing up, and it reads 0.99 lb. When you turn the hairdryer on, so that the hairdryer is pushing the air upward, the reading of the scale increases to 1.09 lb. Explain the change in the reading qualitatively and quantitatively.

Sketch and translate We sketch the process (a) before the hairdryer is turned on and (b) after it is turned on. The system is the hairdryer (with the propeller). We point the positive y-axis down. We know that the force that the scale exerts on the hairdryer when it is off is $F_{S\text{ on HDoff}} = 0.99\text{ lb} = 4.40\text{ N}$. When the hairdryer is on, the force the scale exerts on it is $F_{S\text{ on HDon}} = 1.09\text{ lb} = 4.85\text{ N}$. We need to qualitatively explain the increase of the reading and then explain the quantitative increase of 0.45 N.

(CONTINUED)

Simplify and diagram After the hairdryer is turned on, the scale moves downward a little, but very quickly the situation stabilizes. Thus we will assume that the turned-on hairdryer is not moving with respect to the scale; the scale is stationary after it reaches the reading of 4.85 N. Therefore, the acceleration of the system is zero. There are two objects that interact with the dryer: Earth and the scale. We draw a force diagram for the system (a) when the hairdryer is off and (b) when it is on. The force that Earth exerts on the dryer is the same in both experiments. If diagram (a) is correct, this means that diagram (b) needs an additional downward force of 0.45 N to explain the increase in the reading. What object is exerting this force? Remember that when the dryer is on, the propeller inside is rotating. It pushes the air up, exerting a force $F_{\text{HDon on A}}$; therefore, according to Newton's third law, the air should push the propeller and consequently the whole hairdryer down. Accordingly, we add another force to the diagram in (b), $F_{\text{A on HDon}}$, so that the sum of the forces is still zero. We can now determine the magnitude of this force using the reading of the scale.

Represent mathematically Using the force diagram in (b) we can write

$$a_y = \frac{\Sigma F_y}{m_{\text{HD}}} = \frac{F_{\text{E on HDon}\,y} + F_{\text{S on HDon}\,y} + F_{\text{A on HDon}\,y}}{m_{\text{HD}}}$$

$$= \frac{F_{\text{E on HDon}} + (-F_{\text{S on HDon}}) + F_{\text{A on HDon}}}{m_{\text{HD}}} = 0$$

$$\Rightarrow F_{\text{A on HDon}} = F_{\text{S on HDon}} + (-F_{\text{E on HDon}})$$

Solve and evaluate Using the last equation from the previous step, we find the force that the air exerts on the hairdryer:

$$F_{\text{A on HDon}} = F_{\text{S on HDon}} + (-F_{\text{E on HDon}}) = 4.85\ \text{N} - 4.45\ \text{N} = 0.45\ \text{N}$$

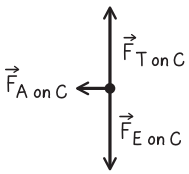
The result makes sense. The magnitude is smaller than the force Earth exerts on the hairdryer but not insignificant. Such an increase in supporting force can explain an observation you may have made while watering plants with a hose. If the flow of water is strong, you can feel the expelled water pushing back on the hose. The same principle explains the behavior of a rotating sprinkler.

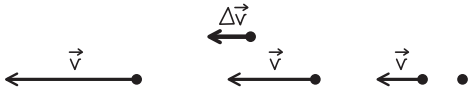
Try it yourself An 80-kg basketball player pushes off a gym floor exerting a force that is 4 times greater than the force Earth exerts on him and that the push lasts 0.10 s (unrealistically short). Estimate how fast he is moving when he leaves the floor?

Answer About 3 m/s. He would move faster if he took longer to push off while exerting the same force.

EXAMPLE 3.8 Learning to linearize data

Alex is investigating the motion of a battery-powered fan attached to a low-friction cart (a fan cart) that is moving on a horizontal track. As the fan blades rotate, they exert a force on the air, and the air exerts an equal and opposite force on the blades, making the cart move (an analogy for the fan cart is a hairdryer on wheels). Using a motion detector, Alex finds that the cart moves with constant acceleration. He also measures how the acceleration of the cart a_x depends on the mass of the objects that he adds to the cart (m_{added}). His measurements are shown in the table below.



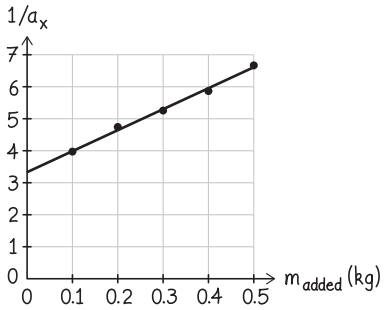


m_{added} (kg)	a_x (m/s^2)
0.10	0.25
0.20	0.21
0.30	0.19
0.40	0.17
0.50	0.15

(a) Draw a force diagram for the cart and use it to explain why the cart moves at constant acceleration for fixed added mass. (b) Two physical quantities that are not listed in the table affect the motion of the cart. Determine these two quantities using the data above. (Hint: Rearrange the mathematical expression for the acceleration of the cart to obtain linear dependence on added mass and then plot the graph using the data in the table.)

Sketch and translate The cart is moving to the left on a horizontal surface. The acceleration of the cart is also to the left due to the fan pushing air to the right (the fan works in a similar way to the hairdryer that we investigated in the previous example). We know the masses of the additional objects on the cart and the respective accelerations. We also know that the acceleration of any system is affected by the sum of the forces exerted on it and the system's mass. Because the mass of the cart (together with the fan) contributes to the system's mass, we hypothesize that the quantities that we need to determine are the sum of the forces and the mass of the cart.

Simplify and diagram We assume that the fan cart can be modeled as a point-like object and that the track is smooth, so we do not need to worry about friction. The only objects interacting with the cart (C) are Earth (E), the track (T), and the air (A). The motion diagram and the force diagram for the cart are shown in the figures below and at right. From the force diagram, we see that the forces exerted on the cart by Earth and the track add to zero, and the only force that is causing the acceleration of the cart to the left is the force exerted by the air.



Represent mathematically We write Newton's second law in component form along the axis of motion:

$$a_x = \frac{F_{\text{A on C}}}{m_{\text{added}} + m_{\text{C}}}$$

Since m_{added} is changed in each experiment (it's an independent variable), it is useful to rearrange the equation so that it is a linear function with linear dependence on m_{added}:

$$\frac{1}{a_x} = \frac{m_{\text{added}} + m_{\text{C}}}{F_{\text{A on C}}} = \frac{m_{\text{added}}}{F_{\text{A on C}}} + \frac{m_{\text{C}}}{F_{\text{A on C}}}$$

and to plot $1/a_x$ against m_{added} (see graph at right). The function for $1/a_x$ is a linear function of the form $mx + b$; thus $m = 1/F_{\text{A on C}}$ is the slope of the graph and the intercept is $b = m_{\text{C}}/F_{\text{A on C}}$. (Do not confuse m for the slope with the symbol m for mass.)

Solve and evaluate The intercept of the graph with the vertical axis is 1 divided by the acceleration the cart would have had if the added mass was zero. Thus $m_{\text{C}}/F_{\text{A on C}} = 3.35\ \text{kg/N}$.

We can find the slope of the graph as Δy divided by Δx. For example, when $\Delta y = 6 - 3.35$ and $\Delta x = 0.4 - 0$, this ratio is $2.65/0.4 = 6.63$. The slope of the graph is thus

$$\frac{1}{F_{\text{A on C}}} = \frac{\Delta y}{\Delta x} = 6.63\,\frac{1}{\text{N}}$$

Therefore, $F_{\text{A on C}} = 0.15$ N and $m_{\text{C}} = 0.51$ kg.

Try it yourself How would the graph change (consider intercept and slope) if you placed a second fan on the same cart and repeat the experiment?

Answer The slope of the graph is inversely proportional to the force exerted by the air on the cart; therefore the slope will be cut in half. The intercept is inversely proportional to the force that the air exerts on the cart and directly proportional to the mass of the cart and fans, therefore there is not enough data to determine it. But if we assume that the mass of the fan is much smaller than the mass of the cart, then the intercept will be between the original one and half of its value.

REVIEW QUESTION 3.8 Is the following sentence true? When you hold a heavy object in your hands, you exert the same magnitude force on the object as the object exerts on you but in the opposite direction, and because these forces add to zero, the object stays at rest.

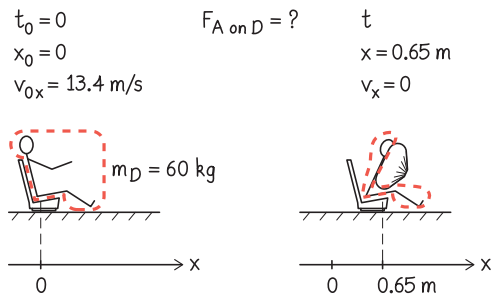
3.9 Seat belts and air bags

At the beginning of the chapter we posed a question about air bags. How do they save lives? We now have all the physics needed to investigate this question. Consider **Figure 3.7**. An air bag is like a balloon that is packed in a small box in the steering wheel or the passenger side dashboard. Air bags are designed to deploy when a car has a negative acceleration of magnitude $10g$ [$10(9.8\ \text{m/s}^2) = 98\ \text{m/s}^2 \approx 100\ \text{m/s}^2$] or more. When a car has such a rapid decrease in speed, the bag inflates with nitrogen gas in about 0.04 s and forms a cushion for the occupant's chest and head. The bag has two important effects:

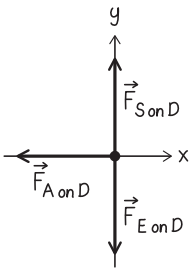
1. It spreads the force that stops the person over a larger area of the body.
2. It increases the stopping distance, and consequently the stopping time interval, thus reducing the average force stopping the occupant.

Why is spreading the stopping force over a larger area of the body an advantage? If a person uses only a seat belt, his head is not belted to the seat and tends to continue moving forward during a collision, even though his chest and waist are restrained. To stop the head without an air bag, the neck must exert considerable force on the head. This can cause a dangerous stretching of the spinal cord and muscles of the neck, a phenomenon known as "whiplash." The air bag exerts a more uniform force across the upper body and head and helps all parts to stop together.

FIGURE 3.7 An air bag stops a crash test dummy during a collision.



How does the air bag increase the stopping distance? Suppose a test car is traveling at a constant speed of 13.4 m/s (30 mi/h) until it collides head-on with a concrete wall. The front of the car crumples about 0.65 m. A crash test dummy is rigidly attached to the car's seat and is further protected by the rapidly inflating air bag. The dummy also travels about 0.65 m before coming to rest. Without an air bag or a seat belt, the dummy would continue to move forward at the initial velocity of the car. It would then crash into the steering wheel or windshield of the stopped car and stop in a distance much less than 0.65 m—like flying into a rigid wall. The smaller the stopping distance, the greater the acceleration, and therefore the greater the force that is exerted on the dummy. Let's estimate the average force exerted by the air bag on the body during a collision.



EXAMPLE 3.9 Force exerted by air bag on driver during collision

A 60-kg crash test dummy moving at 13.4 m/s (30 mi/h) stops during a collision in a distance of 0.65 m. Estimate the magnitude of the average force that the air bag and seat belt exert on the dummy.

Sketch and translate We sketch and label the situation as shown below, choosing the crash test dummy as the system. The positive x-direction is in the direction of motion, and the origin is at the position of the dummy at the start of the collision.

Simplify and diagram We model the dummy D as a point-like object and assume that the primary force exerted on the dummy while stopping is due to the air bag and seat belt's $\vec{F}_{\text{A on D}}$, shown in the force diagram. We can ignore the downward gravitational force that Earth exerts on the dummy $\vec{F}_{\text{E on D}}$ and the upward force that the car seat exerts on the dummy $\vec{F}_{\text{S on D}}$ since they add to zero and do not contribute to the acceleration.

Represent mathematically To determine the dummy's acceleration, we use kinematics:

$$a_x = \frac{v_x^2 - v_{0x}^2}{2(x - x_0)}$$

Once we have the dummy's acceleration, we apply the x-component form of Newton's second law to find the force exerted by the air bag and seat belts on the dummy:

$$a_x = \frac{F_{\text{A on D}\,x}}{m_{\text{D}}} = \frac{-F_{\text{A on D}}}{m_{\text{D}}} = -\frac{F_{\text{A on D}}}{m_{\text{D}}}$$

$$\Rightarrow F_{\text{A on D}} = -m_{\text{D}} a_x$$

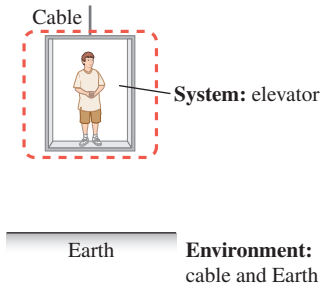
Solve and evaluate We know that $v_{0x} = +13.4$ m/s and $v_x = 0$ (the dummy has stopped). The initial position of the dummy is $x_0 = 0$ and the final position is $x = 0.65$ m. The acceleration of the dummy while in contact with the air bag and seat belt is

$$a_x = \frac{0^2 - (13.4\text{ m/s})^2}{2(0.65\text{ m} - 0\text{ m})} = -138\text{ m/s}^2$$

Thus, the magnitude of the average force exerted by the air bag and seat belt on the dummy is

$$F_{\text{A on D}} = -(60\text{ kg})(-138\text{ m/s}^2) = 8300\text{ N}$$

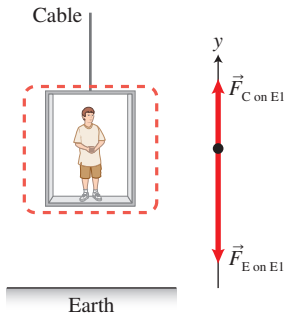
This force [8300 N(1 lb/4.45 N) = 1900 lb] is almost 1 ton. Is this estimate reasonable? The magnitude is large, but experiments with crash test dummies in the real world are consistent with a force this large in magnitude, a very survivable collision.



Try it yourself Find the acceleration of the dummy and the magnitude of the average force needed to stop the dummy if it is not belted, has no air bag, and stops in 0.1 m when hitting a hard surface.

Answer -900 m/s^2 and 54,000 N.

REVIEW QUESTION 3.9 Explain how an air bag and seat belt reduce the force exerted on the driver of a car during a collision.

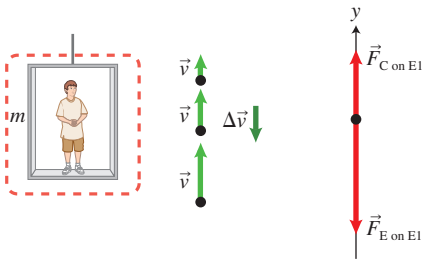


Summary

A **system** is circled in a sketch of a process. Other objects that interact with the system are called the **environment**. (Sections 3.1 and 3.5)

The **force** that one object exerts on another characterizes an interaction between the two objects (a pull or a push). The unit of force is the newton (N); $1\ \text{N} = (1\ \text{kg})(1\ \text{m/s}^2)$. (Sections 3.1 and 3.5)

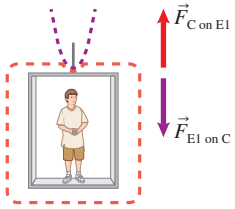
A **force diagram** represents the forces that external objects exert on the system. The arrows in the diagram point in the directions of the forces, and their lengths indicate the relative magnitudes of the forces. (Sections 3.1 and 3.2)



$\vec{F}_{\text{E on O}}$

Interacting objects

A force is denoted by the symbol $\vec{F}$ with two subscripts indicating the object that is exerting the force and the system object.



Newton's first law of motion If no other objects exert forces on a system or if the forces exerted on the system add to zero, then the system continues moving at constant velocity (as seen by observers in inertial reference frames). (Section 3.4)

Newton's second law The acceleration a_{S} of a system is proportional to the sum of the forces that other objects exert on the system and inversely proportional to its mass m. (Section 3.5)

$$\vec{a}_{\text{S}} = \frac{\Sigma \vec{F}_{\text{on S}}}{m_{\text{S}}} = \frac{\vec{F}_{1\text{ on S}} + \vec{F}_{2\text{ on S}} + \cdots}{m_{\text{S}}} \qquad \text{Eq. (3.6)}$$

Newton's third law Two objects exert equal-magnitude and opposite direction forces of the same type on each other. (Section 3.8)

$$\vec{F}_{1\text{ on }2} = -\vec{F}_{2\text{ on }1} \qquad \text{Eq. (3.9)}$$

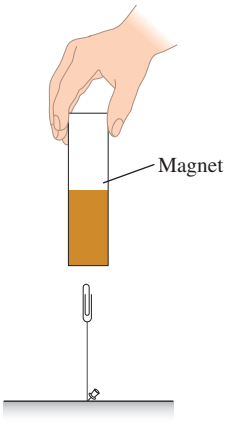
The **gravitational force** $\vec{F}_{\text{E on O}}$ that Earth exerts on an object of mass m when on or near Earth's surface depends on the gravitational coefficient g of Earth. If on or near another planet or the Moon, the gravitational coefficient near those objects is different. (Section 3.6)

Magnitude

$$F_{\text{E on O}} = m_{\text{O}} g \qquad \text{Eq. (3.8)}$$

where

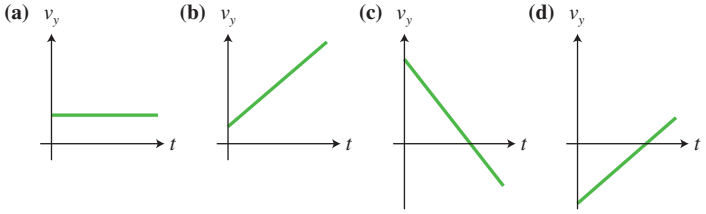
$$g = 9.8\ \text{m/s}^2 = 9.8\ \text{N/kg}$$



when the object is on or near Earth's surface.

Questions

Multiple Choice Questions



1. An upward-moving elevator slows to a stop as it approaches the top floor. Which answer below best describes the relative magnitudes of the upward force that the cable exerts on the elevator $\vec{F}_{\text{C on El}}$ and the downward gravitational force that Earth exerts on the elevator $\vec{F}_{\text{E on El}}$?
   (a) $F_{\text{C on El}} > F_{\text{E on El}}$ (b) $F_{\text{C on El}} = F_{\text{E on El}}$
   (c) $F_{\text{C on El}} < F_{\text{E on El}}$
   (d) Not enough information is given to answer the question.
2. You apply the brakes of your car abruptly and your book starts sliding off the front seat. Three observers explain this differently. Observer A says that the book continued moving and the car accelerated from underneath it. Observer B says that the car pushed forward on the book. Observer C says that she must be in a noninertial reference frame because the book started moving without any extra objects interacting with it. Which of the observers is correct?
   (a) A (b) B
   (c) C (d) A and C
   (e) All of the observers
3. Which of the statements below explains why a child lurches forward in a stroller when you abruptly stop the stroller?
   (a) The child does not lurch forward but instead continues her motion.
   (b) Your pull on the stroller causes the child to move in the opposite direction.
   (c) Newton's third law
4. Which observers can explain the phenomenon of whiplash, which occurs when a car stops abruptly, using Newton's laws?
   (a) The driver of the car (b) A passenger in the car
   (c) An observer on the sidewalk beside the car and road
5. Which vector quantities describing a moving object are always in the same direction?
   (a) Velocity and acceleration
   (b) Velocity and the sum of the forces
   (c) Acceleration and the sum of the forces
   (d) Acceleration and force
   (e) Both b and c are correct.
6. You have probably observed that magnets attract objects made of certain metals, such as steel. You tie a steel paperclip to a tabletop with string and bring a strong magnet above it so that the paperclip is positioned as shown in **Figure Q3.6**. Which answer correctly compares the magnitude of the force exerted by the magnet on the paperclip to the magnitude of the force exerted by the paperclip on the magnet?
   (a) $F_{\text{magnet on clip}} > F_{\text{clip on magnet}}$
   (b) $F_{\text{magnet on clip}} < F_{\text{clip on magnet}}$
   (c) $F_{\text{magnet on clip}} = F_{\text{clip on magnet}}$

FIGURE Q3.6

7. Which of the following velocity-versus-time graphs represent the motion of the object for which $\Sigma F_y > 0$? Choose all answers that are correct.

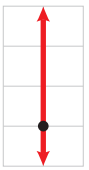


FIGURE Q3.7

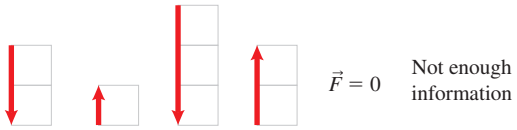
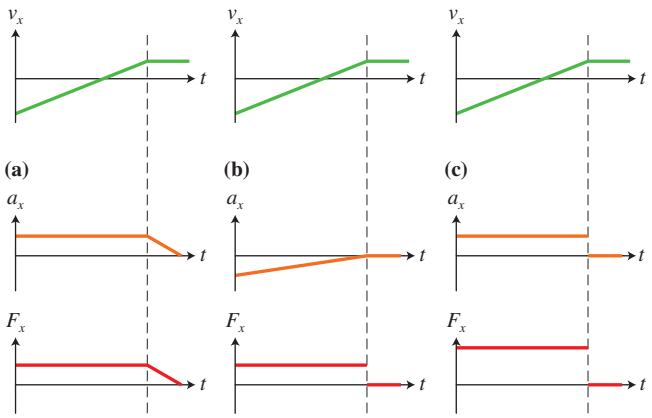


8. A book sits on a tabletop. What force is the Newton's third law pair to the force that Earth exerts on the book? Choose the correct answer with the best explanation.
   (a) The force that the table exerts on the book because it is equal and opposite in direction to the force that Earth exerts on the book
   (b) The force that the table exerts on the book because the table and the book are touching each other
   (c) The force that the table exerts on the book because it describes the same interaction
   (d) The force that the book exerts on Earth because it describes the same interaction
   (e) The force that the book exerts on Earth because it is equal and opposite in direction to the force that Earth exerts on the book
9. A spaceship moves in outer space. What happens to its motion if there are no external forces exerted on it? If there is a constant force exerted on it in the direction of its motion? If something exerts a force opposite its motion?
   (a) It keeps moving; it speeds up with constant acceleration; it slows down with constant acceleration.
   (b) It slows down; it moves with constant velocity; it slows down.
   (c) It slows down; it moves with constant velocity; it stops instantly.
10. A 0.10-kg apple falls on Earth, whose mass is about 6×10^{24} kg. Which is true of the gravitational force that Earth exerts on the apple?
    (a) It is bigger than the force that the apple exerts on Earth by almost 25 orders of magnitude.
    (b) It is the same magnitude.
    (c) We do not know the magnitude of the force the apple exerts on Earth.
11. A man stands on a scale and holds a heavy object in his hands. What happens to the scale reading if the man quickly lifts the object upward and then stops lifting it?
    (a) The reading increases, returns briefly to the reading when standing stationary, then decreases.
    (b) The reading decreases, returns briefly to the reading when standing stationary, then increases.
    (c) Nothing, since the mass of the person with the object remains the same. Thus the reading does not change.
12. You stand on a bathroom scale in a moving elevator. What happens to the scale reading if the cable holding the elevator suddenly breaks?
    (a) The reading will increase.
    (b) The reading will not change.
    (c) The reading will decrease a little.
    (d) The reading will drop to 0 instantly.
13. A person pushes a 10-kg crate, exerting a 200-N force on it, but the crate's acceleration is only 5 m/s^2. Explain.
    (a) The crate pushes back on the person, thus the total force is reduced.
    (b) There are other forces exerted on the crate so that the total force is reduced.
    (c) Not enough information is given to answer the question.
14. Two small balls of the same material, one of mass m and the other of mass $2m$, are dropped simultaneously from the Leaning Tower of Pisa. On which ball does Earth exert a bigger force?
    (a) On the $2m$ ball
    (b) On the m ball
    (c) Earth exerts the same force on both balls because they fall with the same acceleration.
15. A box full of lead and a box of the same size full of feathers are floating inside a spaceship that has left the solar system. Choose equipment that you can use to compare their masses.
    (a) A balance scale
    (b) A digital scale
    (c) A watch with a second hand and a meter stick

16. **Figure Q3.16** shows an unlabeled force diagram for a moving object that is missing one force. The length of the sides of the square grid corresponds to a force magnitude of 1 N. Which additional force has to be exerted on the object so that the object (I) moves at a constant speed, (II) accelerates downward, (III) accelerates upward, and (IV) moves down? For each case, choose all answers from (a) to (f) that are correct.

FIGURE Q3.16



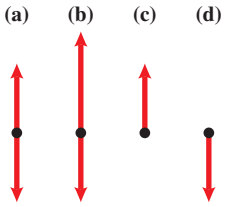
17. A person jumps from a wall and lands stiff-legged. Which statement best explains why the person is less likely to be injured when landing on soft sand than on concrete?
    (a) The concrete can exert a greater force than the sand.
    (b) The person sinks into the sand, increasing the stopping distance.
    (c) The upward acceleration of the person in the sand is less than on concrete, thus the force that the sand exerts on the person is less.
    (d) b and c
    (e) a, b, and c
18. A 3000-kg spaceship is moving away from a space station at a constant speed of 3 m/s. The astronaut in the spaceship decides to return to the space station by switching on engines that expel fuel so that the sum of the forces exerted on the spaceship by the expelled fuel points toward the space station. What is the magnitude of the minimum force needed to bring the spaceship back to the space station?
    (a) 9000 N
    (b) 1000 N
    (c) Any force larger than zero
    (d) The spaceship will keep moving away from the space station no matter how large the force.
    (e) Not enough information is given to answer the question.

Conceptual Questions

19. **Figure Q3.19** is a velocity-versus-time graph for the vertical motion of an object. Choose the correct combination (a, b, or c) of an acceleration-versus-time graph and a force-versus-time graph for the object.

FIGURE Q3.19

20. Explain the purpose of crumple zones, that is, the front of a car that collapses during a collision.
21. Explain why when landing on a firm surface after a fall you should not land with stiff legs.
22. A small car bumps into a large truck. Compare the forces that the truck exerts on the car and the car exerts on the truck if before the collision (a) the truck was stationary and the car was moving; (b) the car and the truck were moving in opposite directions; (c) the car and the truck were moving in the same direction.
23. You are pulling a sled. Compare the forces that you exert on the sled and the sled exerts on you if you (a) move at constant velocity; (b) speed up; (c) slow down.
24. You stand on a bathroom scale in a moving elevator. The elevator is moving up at increasing speed. The acceleration is constant. Draw three consecutive force diagrams for you.
25. You are holding a 100-g apple. (a) What is the force that you exert on the apple? (b) What is the force that the apple exerts on you? Support your answer with a motion diagram and a force diagram.
26. You throw a 100-g apple upward. (a) While the apple is still in your hand (we'll call this period "the throw"), is the force that you exert on the apple more than, less than, or the same as the force that you exert on the apple when you are holding it at rest? (b) Support your answer with a motion diagram for the throw and a force diagram for one instant during the throw. (c) Is the force that the apple exerts on you at this instant more than, less than, or the same as the force that you exert on the apple when you are holding it at rest? Explain your answer.
27. After having been thrown upward, a 100-g apple falls back into your hand and you catch it. (a) While you are catching it, is the force that you exert on the apple more than, less than, or the same as the force that you exert on the apple when you are holding it at rest? (b) Support your answer with a motion diagram and a force diagram for one instant of the catch. (c) Is the force that the apple exerts on you at this instant more than, less than, or the same as the force that you exert on the apple when you are holding it at rest? Explain your answer.



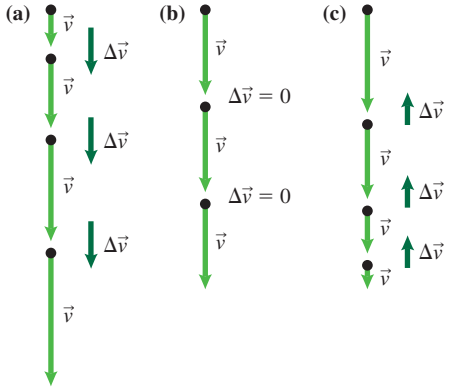
Problems

Below, BIO indicates a problem with a biological or medical focus. Problems labeled EST ask you to estimate the answer to a quantitative problem rather than derive a specific answer. Asterisks indicate the level of difficulty of the problem. Problems with no * are considered to be the least difficult. A single * marks moderately difficult problems. Two ** indicate more difficult problems.

3.1 and 3.2 Describing and representing interactions and Adding and measuring forces

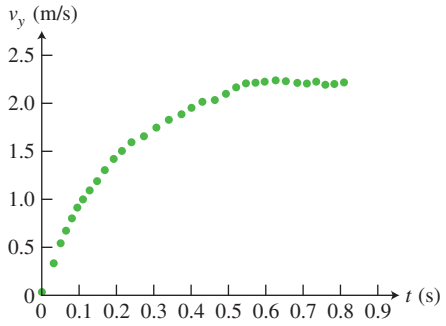
1. * In **Figure P3.1** you see unlabeled force diagrams for balls in different situations. Match the diagrams with the following descriptions. (1) A ball is moving upward after it leaves your hand. (2) You hold a ball in your hand. (3) A ball is falling down. (4) You are throwing a ball (still in your hand) straight up. (5) You are lifting a ball at a constant pace. Explain your choices. Label the forces on the diagrams.

FIGURE P3.1



2. Draw a force diagram (a) for a bag hanging at rest from a spring; (b) for the same bag sitting on a table; and (c) for the same bag that you start to lift so it moves up faster and faster.
3. For each of the following situations, draw the forces exerted on the moving object and identify the other object causing each force. (a) You pull a wagon along a level floor using a rope oriented horizontally. (b) A bus moving on a horizontal road slows down in order to stop. (c) You lift your overnight bag into the overhead compartment on an airplane.
4. You hang a book bag on a spring scale and place the bag on a platform scale so that the platform scale reads 25.7 N and the spring scale reads 17.6 N. (a) Draw a force diagram for the book bag to represent the situation. (b) What is the magnitude of the force that Earth exerts on the bag?

3.3 Conceptual relationship between force and motion



5. A block of dry ice slides at constant velocity along a smooth, horizontal surface. (a) Construct a motion diagram. (b) Draw position- and velocity-versus-time graphs. (c) Construct a force diagram for the block for three instants represented by dots on the motion diagram. Are the diagrams consistent with each other?
6. * You throw a ball upward. (a) Draw a motion diagram and two force diagrams for the ball on its way up and another motion diagram and two force diagrams for the ball on its way down. (b) Represent the motion of the ball with a position-versus-time graph and velocity-versus-time graph.
7. A string pulls horizontally on a cart so that it moves at increasing speed along a smooth horizontal surface. When the cart is moving medium-fast, the pulling is stopped abruptly. (a) Describe in words what happens to the cart's motion when the pulling stops. (b) Illustrate your description with motion diagrams, force diagrams, and position-versus-time and velocity-versus-time graphs. Indicate on the graphs when the pulling stopped. What assumptions did you make?
8. * Solving the previous problem, your friend says that after the string stops pulling, the cart starts slowing down. (a) Explain why your friend would think this way. (b) Do you agree with him? Explain your opinion. (c) Explain how you can design an experiment to test his idea.
9. * A string pulls horizontally on a cart so that it moves at increasing speed along a smooth horizontal surface. When the cart is moving medium-fast, the magnitude of the pulling force is reduced to half its former magnitude. (a) Describe what happens to the cart's motion after the reduction in the string pulling. (b) Illustrate your description with motion diagrams, force diagrams, and position-versus-time and velocity-versus-time graphs.
10. A block of dry ice slides at a constant velocity on a smooth horizontal surface. A second block of dry ice slides twice as fast on the same surface (at a higher constant velocity). Compare the resultant forces exerted on each block. Explain your reasoning.
11. Three motion diagrams for a moving elevator are shown in **Figure P3.11**. Construct two force diagrams (for two consecutive moments) for the elevator for *each* motion diagram. Be sure that the lengths of the force arrows are the appropriate relative lengths and that there is consistency between the force diagrams and the motion diagrams. What assumptions did you make?

FIGURE P3.11

12. * A student holds a thin aluminum pie pan horizontally 2 m above the ground and releases it. Using a motion detector, she obtains the graph shown in **Figure P3.12**. Based on her measurements, (a) draw force diagrams for the pie pan at times 0.05 s, 0.3 s, and 0.7 s, and (b) estimate the distance that the pan travels once it reaches constant speed.

FIGURE P3.12

13. * Figures P3.11a, b, and c show three motion diagrams for an elevator moving downward. (a) For each diagram, say everything you can about the elevator's motion. (b) Draw a force diagram for each motion diagram. (c) Could you draw a different motion diagram for each force diagram? Explain how that is possible.

3.4 Inertial reference frames and Newton's first law

14. * A train traveling from New York to Philadelphia is passing a station. A ball is sitting on the floor of the train not moving with respect to the train. (a) Draw a force diagram and a motion diagram for the ball as seen by the observers on the train and on the platform. (b) The ball now starts accelerating forward relative to the floor. Draw force and motion diagrams for the ball as seen by the observers on the train and on the platform. Which of the observers can use Newton's first law to explain the ball's acceleration? Explain.
15. * Explain the phenomenon of whiplash from two points of view: that of an observer on the ground and an observer in the car.

3.5 Newton's second law

16. * An astronaut exerts a 100-N force pushing a beam into place on the International Space Station. The beam accelerates at 0.10 m/s^2. Determine the mass of the beam. What is the percent uncertainty in your answer?

17. Four people participate in a rope competition. Two of them pull the rope right, exerting forces of magnitude 330 N and 380 N. The other two pull left, exerting forces of magnitude 300 N and 400 N. What is the sum of the forces exerted on the rope?
18. * **Shot put throw** During a practice shot put throw, the 7.0-kg shot left world champion C. J. Hunter's hand at speed 13 m/s. While making the throw, his hand pushed the shot a distance of 1.7 m. Describe all the physical quantities you can determine using this information. Describe the assumptions you need to make to determine them.
19. * You know the sum of the forces $\Sigma\vec{F}$ exerted on an object of mass m during Δt seconds. The object is at rest at the beginning of the time interval. List three physical quantities that you can determine about that object's motion using this information. Then explain how you will determine them.
20. * You record the displacement of an object as a constant force is exerted on it. (a) If the time interval during which the force is exerted doubles, how does the object's displacement change? Indicate all the assumptions that you made. (b) Explain how your answer changes if one of the assumptions is not valid.
21. * **Equation Jeopardy 1** Invent a problem for which the following equation can be a solution:

$$(40\text{ kg})a_x = 200\text{ N} - 40\text{ N}$$

3.6 and 3.7 Gravitational force law and Skills for applying Newton's second law for one-dimensional processes

22. * **Equation Jeopardy 2** Describe in words a problem for which the following equation is a solution and draw a force diagram that is consistent with the equation (specify the direction of the axis):

$$3.0\text{ m/s}^2 \times 3.0\text{ kg} = +29.4\text{ N} - F_{\text{R on O}}$$

23. **Equation Jeopardy 3** Describe in words a problem for which the following equation is a solution and draw a force diagram that is consistent with the equation (specify the direction of the axis):

$$\frac{0.8\text{ m/s} - 1.2\text{ m/s}}{1.6\text{ s}} = \frac{\Sigma F_x}{50\text{ kg}}$$

24. * **Equation Jeopardy 4** Describe in words a problem for which the following equation is a solution and draw a force diagram that is consistent with the equation (specify the direction of the axis):

$$2.0\text{ m/s}^2 = \frac{196\text{ N} - F_{\text{P on O}}}{20\text{ kg}}$$

25. * **Spider-Man** Spider-Man holds the bottom of an elevator with one hand. With his other hand, he holds a spider cord attached to a 50-kg box of explosives at the bottom of the cord. Determine the force that the cord exerts on the box if (a) the elevator is at rest; (b) the elevator accelerates up at 2.0 m/s^2; (c) the upward-moving elevator's speed decreases at a rate of 2.0 m/s^2; and (d) the elevator falls freely.
26. ** Matt is wearing Rollerblades. Beth pushes him along a hallway with a large spring, keeping the spring compressed and consequently the force that the spring exerts on Matt constant at all times. They conduct several experiments in which Matt starts from rest and travels 12.0 m while carrying objects of different mass in his backpack, recording the time interval for each trip. Their data are shown in the table at right.

Added mass (kg)	Time interval (s)
0	19.0
3.0	19.4
6.0	19.9
9.0	20.3
12.0	20.8
15.0	21.2

(a) Draw a force diagram for Matt and use it to explain why he is moving with a constant acceleration. (b) Two physical quantities that are not listed in the table also affect Matt's motion. Determine these two quantities using the data above. (Hint: This problem requires linearization. See Example 3.8 for help.)

27. * **Stuntwoman** The downward acceleration of a 60-kg stuntwoman near the end of a fall from a very high building is 7.0 m/s^2. What resistive force does the air exert on her body at that point?
28. EST Estimate the average force that a baseball pitcher's hand exerts on a 0.145-kg baseball as he throws a 40 m/s (90 mi/h) pitch. Indicate all of the assumptions you made.
29. * **Super Hornet jet takeoff** A 2.1×10^4-kg F-18 Super Hornet jet airplane (see Figure P3.29) goes from zero to 265 km/h in 90 m during takeoff from the flight deck of the USS Nimitz aircraft carrier. What physical quantities can you determine using this information? Make a list and determine the values of three of them.

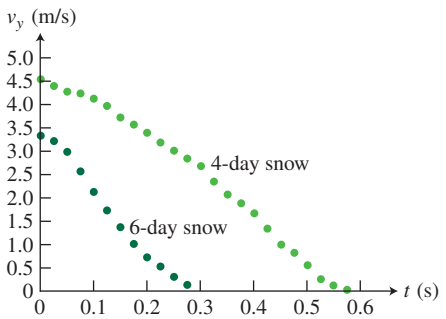


FIGURE P3.29

30. **Lunar Lander** The Lunar Lander of mass 2.0×10^4 kg made the last 150 m of its trip to the Moon's surface in 120 s, descending at approximately constant speed. The *Handbook of Lunar Pilots* indicates that the gravitational constant on the Moon is 1.633 N/kg. Using these quantities, what can you learn about the Lunar Lander's motion?
31. Aisha throws a 0.3-kg ball upward. Frances, standing on a balcony above Aisha, catches the ball by exerting a 1-N downward force on the ball. (a) Draw a motion diagram and a force diagram for the ball during the time interval when Frances is catching it. (b) Determine the acceleration of the ball.
32. * Students Lucia, Isabel, and Austin are investigating how snow stops a dropped 500-g lemon juice bottle. In particular, they are interested in how the force exerted by the snow depends on the age of the snow. They take high-speed videos of the bottle while it sinks into the snow, taking their first set of measurements 4 days after fresh snowfall and the second set of measurements 2 days later. After analyzing the videos frame by frame (see photo), they plot a graph that shows how the velocity of the bottle from the moment the bottle touches the snow changes for both types of snow (Figure P3.32).

FIGURE P3.32

They each explain their results as follows:

Lucia: The 6-day snow exerts a larger force on the bottle because it stops the bottle in a shorter time.

Isabel: The time taken to stop the bottle does not say much about the force. The 6-day snow exerts a larger force on the bottle because the slope of its $v_y(t)$ graph is steeper.

Austin: We cannot compare the forces exerted by the snow because the initial velocities are different. We need to repeat the experiments and make sure we always drop the bottle from the same height.

Explain how each student reached her/his conclusion and decide who (if anyone) is correct. Indicate any assumptions that you have made.

33. * **Astronaut** Karen Nyberg, a 60-kg astronaut, sits on a bathroom scale in a rocket that is taking off vertically with an acceleration of $3g$. What does the scale read?
34. * A 0.10-kg apple falls off a tree branch that is 2.0 m above the grass. The apple sinks 0.060 m into the grass while stopping. Determine the force that the grass exerts on the apple while stopping it. Indicate any assumptions you made.
35. ** An 80-kg fireman slides 5.0 m down a fire pole. He holds the pole, which exerts a 500-N steady resistive force on the fireman. At the bottom he slows to a stop in 0.40 m by bending his knees. What can you determine using this information? Determine it.

3.8 Forces come in pairs: Newton's third law

36. * Earth exerts a 1.0-N gravitational force on an apple as it falls toward the ground. (a) What force does the apple exert on Earth? (b) Compare the accelerations of the apple and Earth due to these forces. The mass of the apple is about 100 g and the mass of Earth is about 6×10^{24} kg.
37. * You push a bowling ball down the lane toward the pins. Draw force diagrams for the ball (a) just before you let it go; (b) when the ball is rolling (for two clock readings); (c) as the ball is hitting a bowling pin. (d) For each force exerted on the ball in parts (a)–(c), draw the Newton's third law force beside the force diagram, and indicate the object on which these third law forces are exerted.
38. * EST (a) A 50-kg skater initially at rest throws a 4-kg medicine ball horizontally. Describe what happens to the skater and to the ball. (b) Estimate the acceleration of the ball during the throw and of the skater using a reasonable value for the force that a skater can exert on the medicine ball. (c) The skater moving to the right catches the ball moving to the left. After the catch, both objects move to the right. Draw force diagrams for the skater and for the ball while the ball is being caught.
39. ** EST Basketball player LeBron James can jump vertically over 0.9 m. Estimate the force that he exerts on the surface of the basketball court as he jumps. (a) Compare this force with the force that the surface exerts on James. Describe all assumptions used in your estimate and state how each assumption affects the result. (b) Repeat the problem looking at the time interval when he is landing back on the floor.
40. * EST The Scottish Tug of War Association contests involve eight-person teams pulling on a rope in opposite directions. Estimate the magnitude of the force that the rope exerts on each team. Indicate any assumptions you made and include a force diagram for a short section of the rope.
41. Consider the experiment described in Question 3.6 (Figure Q3.6). (a) Draw force diagrams for the magnet and for the paperclip. (b) Which of the forces that you have drawn are pairs according to Newton's third law? Assume all objects are at rest. (c) If the mass of the magnet is 0.300 kg and the force exerted by the hand on the magnet is 3.18 N, what is the magnitude of the force exerted by the paperclip on the magnet? (d) Can you determine the mass of the paperclip based on these data? Explain.
42. * EST A friend drops a 0.625-kg basketball from 2 m above you. (a) Estimate the smallest force that the basketball exerts on your hands while you are catching it. (b) How does it compare to the force that you have to exert on the ball to catch it? Use force diagrams to support your answer.

3.9 Seat belts and air bags

43. **Car safety** The National Transportation Safety Board indicates that a person in a car crash has a reasonable chance of survival if his or her acceleration is less than 300 m/s^2. (a) What magnitude force would cause this acceleration in such a collision? (b) What stopping distance is needed if the initial speed before the collision is 20 m/s (72 km/h, or 45 mi/h)? (c) Indicate any assumptions you made.
44. * A 70-kg person in a moving car stops during a car collision in a distance of 0.60 m. The stopping force that the air bag exerts on the person is 8000 N. Name at least three physical quantities describing the person's motion that you can determine using this information, and then determine them.

General Problems

45. * BIO EST **Left ventricle pumping** The lower left chamber of the heart (the left ventricle) pumps blood into the aorta. According to biophysical studies, a left ventricular contraction lasts about 0.20 s and pumps 88 g of blood. This blood starts at rest and after 0.20 s is moving through the aorta at about 2 m/s. (a) Estimate the force exerted on the blood by the left ventricle. (b) What is the percent uncertainty in your answer? (c) What assumptions did you make? Did the assumptions increase or decrease the calculated value of the force compared to the actual value?
46. ** EST **Acorn hits deck** You are sitting on a deck of your house surrounded by oak trees. You hear the sound of an acorn hitting the deck. You wonder if an acorn will do much damage if instead of the deck it hits your head. Make appropriate estimations and assumptions and provide a reasonable answer.
47. ** EST **Olympic dive** During a practice dive, Olympic diver Fu Mingxia reached a maximum height of 5.0 m above the water. She came to rest 0.40 s after hitting the water. Estimate the average force that the water exerted on her while stopping her.
48. * Komila knows that an egg breaks if it falls onto a concrete floor from a height of 0.4 m. She finds, however, that an egg does not break when it falls from the same height onto a floor that is covered with a 2.0-cm-thick carpet. Try to explain the outcome of her experiments. Draw a force diagram for the egg just before it stops. Based on your explanation, predict what the thickness of the carpet should be for an egg to survive a drop from a height of 1.0 m. Indicate any assumptions you have made.
49. ** EST You are doing squats on a bathroom scale. You decide to push off the scale and jump up. Estimate the reading as you push off and as you land. Indicate any assumptions you made.
50. ** EST Estimate the horizontal speed of the runner shown in **Figure P3.50** at the instant she leaves contact with the starting blocks. Indicate any assumptions you made.

Reading Passage Problems

Col. John Stapp crash tests From 1946 through 1958, Col. John Stapp headed the U.S. Air Force Aero Medical Laboratory's studies of the human body's ability to tolerate high accelerations during plane crashes. Conventional wisdom at the time indicated that a plane's negative acceleration should not exceed 180 m/s^2 (18 times gravitational acceleration, or $18g$). Stapp and his colleagues built a 700-kg "Gee Whiz" rocket sled, track, and stopping pistons to measure human tolerance to high acceleration. Starting in June 1949, Stapp and other live subjects rode the sled. In one of Stapp's rides, the sled started at rest and 360 m later was traveling at speed 67 m/s when its braking system was applied, stopping the sled in 6.0 m. He had demonstrated that $18g$ was not a limit for human deceleration.

53. In an early practice run while the rocket sled was stopping, a passenger dummy broke its restraining device and the window of the rocket sled and stopped after skidding down the track. What physics principle best explains this outcome?
    (a) Newton's first law
    (b) Newton's second law
    (c) Newton's third law
    (d) The first and second laws
    (e) All three laws

54. What is Stapp's 67 m/s speed in miles per hour?
(a) 30 mi/h (b) 40 mi/h (c) 100 mi/h
(d) 120 mi/h (e) 150 mi/h

55. What is the magnitude of the acceleration of Stapp and his sled as their speed increased from zero to 67 m/s?
(a) 5 m/s^2 (b) 6 m/s^2 (c) 10 m/s^2
(d) 12 m/s^2 (e) 14 m/s^2

56. What is the magnitude of the acceleration of Stapp and his sled as their speed decreased from 67 m/s to zero?
(a) $12g$ (b) $19g$ (c) $26g$
(d) $38g$ (e) $48g$

57. What is the average force exerted by the restraining system on 80-kg Stapp while his speed decreased from 67 m/s to zero in a distance of 6.0 m?
(a) 10,000 N (b) 20,000 N (c) 30,000 N
(d) 40,000 N (e) 50,000 N

58. What is the time interval for Stapp and his sled to stop as their speed decreased from 67 m/s to zero?
(a) 0.09 s (b) 0.18 s (c) 0.34 s
(d) 5.4 s (e) 10.8 s

Using proportions A proportion is defined as an equality between two ratios; for instance, $a/b = c/d$. Proportions can be used to determine the expected change in one quantity when another quantity changes. Suppose, for example, that the speed of a car doubles. By what factor does the stopping distance of the car change? Proportions can also be used to answer everyday questions, such as whether a large container or a small container of a product is a better buy on a cost-per-unit-mass basis.

Suppose that a small pizza costs a certain amount. How much should a larger pizza of the same thickness cost? If the cost depends on the amount of ingredients used, then the cost should increase in proportion to the pizza's area and not in proportion to its diameter:

$$\text{Cost} = k(\text{Area}) = k(\pi r^2) \tag{3.10}$$

where r is the radius of the pizza and k is a constant that depends on the price of the ingredients per unit area. If the area of the pizza doubles, the cost should double, but k remains unchanged.

Let us rearrange Eq. (3.10) so the two variable quantities (cost and radius) are on the right side of the equation and the constants are on the left:

$$k\pi = \frac{\text{Cost}}{r^2}$$

This equation should apply to any size pizza. If r increases, the cost should increase so that the ratio Cost/r^2 remains constant. Thus, we can write a proportion for pizzas of different sizes:

$$k\pi = \frac{\text{Cost}}{r^2} = \frac{\text{Cost}'}{r'^2}$$

For example, if a 3.5-in.-radius pizza costs \$4.00, then a 5.0-in. radius pizza should cost

$$\text{Cost}' = \frac{r'^2}{r^2}\text{Cost} = \frac{(5.0\text{ in})^2}{(3.5\text{ in})^2}(\$4.00) = \$8.20$$

This process can be used for most equations relating two quantities that change while all other quantities remain constant.

59. The downward distance d that an object falls in a time interval t if starting at rest is $d = \frac{1}{2}at^2$. On the Moon, a rock falls 10.0 m in 3.50 s. How far will the object fall in 5.00 s, assuming the same acceleration?
(a) 14.3 m (b) 20.4 m (c) 4.90 m
(d) 7.00 m (e) 10.0 m

60. The downward distance d that an object falls in a time interval t if starting at rest is $d = \frac{1}{2}at^2$. On the Moon, a rock falls 10.0 m in 3.50 s. What time interval t is needed for it to fall 15.0 m, assuming the same acceleration?
(a) 2.33 s (b) 2.86 s (c) 3.50 s
(d) 4.29 s (e) 5.25 s

61. A car's braking distance d (the distance it travels if rolling to a stop after the brakes are applied) depends on its initial speed v_0, the maximum friction force $\vec{f}_{\text{R on C}}$ exerted by the road on the car, and the car's mass m according to the equation

$$\frac{2f_{s\,\max}}{m}d = v_0^2$$

Suppose the braking distance for a particular car and road surface is 26 m when the initial speed is 18 m/s. What is the braking distance when traveling at 27 m/s?
(a) 59 m (b) 39 m (c) 26 m
(d) 17 m (e) 12 m

62. You decide to open a pizza parlor. The ingredients require that you charge \$4.50 for a 7.0-in.-diameter pizza. How large should you make a pizza whose price is \$10.00, assuming the cost is based entirely on the cost of ingredients?
(a) 1.4 in. (b) 3.1 in. (c) 7.0 in.
(d) 10 in. (e) 16 in.

63. A circular wool quilt of 1.2 m diameter costs \$200. What should the price of a 1.6-m-diameter quilt be if it is to have the same cost per unit area?
(a) \$110 (b) \$150 (c) \$270 (d) \$360

Applying Newton's Laws

- **How does knowing physics help human cannonballs safely perform their tricks?**
- **Who would win a race down a waterslide: an adult or a small child?**
- **How does friction help us walk?**

On March 10, 2011, David Smith, Jr., set the record for the distance traveled by a human cannonball—59 m, improving the record set by his father by more than 2 m. A human cannonball is a performer who is ejected from a cannon by a compressed spring or compressed air and lands on either a horizontal net or an inflated bag. How does the designer of the performance know where to put the net or bag? We'll learn how to make that determination in this chapter.

BE SURE YOU KNOW HOW TO:

- Use trigonometric functions (Mathematics appendix).
- Use motion diagrams and mathematical equations to describe motion (Sections 2.2, 2.6, and 2.7).
- Identify a system, construct a force diagram for it, and use the force diagram to apply Newton's second law (Sections 3.1, 3.5, and 3.7).

WHEN WE FIRST studied force and motion dynamics processes (in Chapter 3), we considered processes in which the forces exerted on an object by other objects were mainly along one axis—the axis along which motion occurred. These processes are common, but most everyday life processes involve forces that are *not* all directed only along the axis of motion. In this chapter we will learn to apply Newton's laws to those more complex processes.

4.1 Vectors in two dimensions and force components

To apply Newton's second law to situations in which the force vectors do not all point along the coordinate axes, we need to learn how to break forces into their *vector components* (also called *component vectors*). We start by using a vector quantity with which we are already very familiar—displacement $\vec{d}$, a vector that starts from an object's initial position and ends at its final position.

Finding vector components

Suppose you want to take a trip and can reach your final destination in two different ways (see **Figure 4.1**). Route 1 is a direct path that is represented by a displacement vector $\vec{C}$. Its tail represents your initial location and its head represents your final destination. Route 2 goes along two roads, represented by displacement vectors $\vec{A}$ and $\vec{B}$, that are perpendicular to each other. You first travel along $\vec{A}$, then along $\vec{B}$, and end at the same final destination.

Route 2 is an example of how to add displacement vectors graphically (you learned vector addition in Chapter 2). Because the initial and final positions are the same for either route, we say that $\vec{C} = \vec{A} + \vec{B}$. Any vector (for example, $\vec{C}$) can be replaced by two perpendicular vectors (for example, $\vec{A}$ and $\vec{B}$) if these two vectors graphically add to equal $\vec{C}$, as illustrated in Figure 4.1.

Because forces are vectors, we can also replace a force $\vec{F}$ by two perpendicular forces $\vec{F}_x$ and $\vec{F}_y$ that graphically add to equal the original force. Suppose, for example, we place a small box on a very smooth surface. The box is stationary. Then we attach strings and spring scales to the box and pull in opposite directions, exerting a 5-N force on each string at angles of 37° relative to the plus or minus x-axis (**Figure 4.2a**). These two forces balance, and the box remains stationary.

Now, let's replace the string and spring scale pulling at 37° relative to the positive x-axis with two strings and two spring scales, one pulling along the x-axis and the other along the y-axis (Figure 4.2b). We find that if the x-axis scale pulls exerting a 4-N force and the y-axis scale pulls exerting a 3-N force, the box again remains stationary. Thus, these two forces have the same effect on the box as the single 5-N force exerted on the box at an angle of 37° above the positive x-direction.

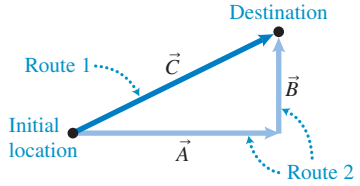
This experimental result is consistent with graphical vector addition, where we find that a 4-N force in the positive x-direction plus a 3-N force in the positive y-direction add to produce a 5-N force at 37° relative to the positive x-axis (Figure 4.2c). The vectors form a "3-4-5" right triangle.

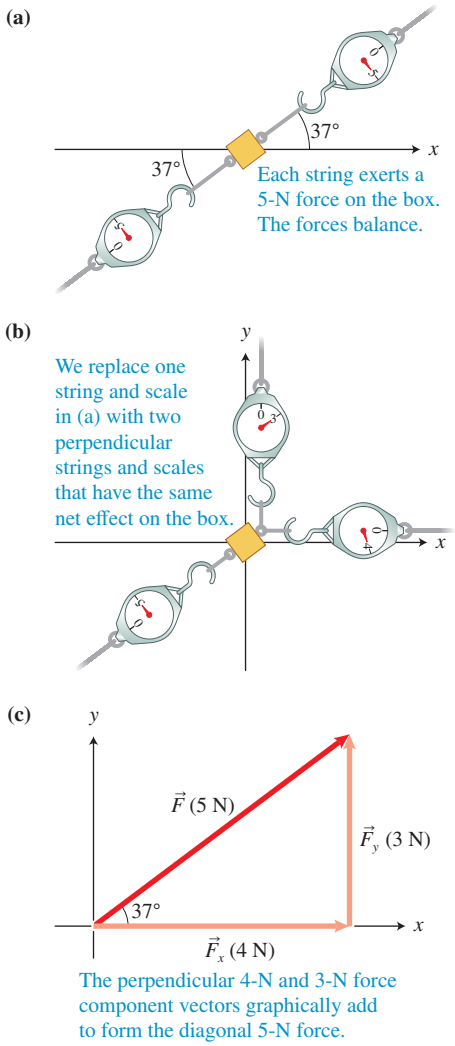
In summary, **we can always replace any force $\vec{F}$ with two perpendicular forces $\vec{F}_x$ and $\vec{F}_y$, as long as the perpendicular forces graphically add to $\vec{F}$** (Figure 4.2c). In this case, the perpendicular forces are along the perpendicular x- and y-axes and are called the x- and y-**vector components** of the original force $\vec{F}$. Since the vector components are also vectors, they are written with a vector symbol above them. Note that $\vec{F}_x + \vec{F}_y = \vec{F}$, just as displacement $\vec{C}$ was identical to the displacement $\vec{A} + \vec{B}$ in Figure 4.1.

Scalar components of a vector

When working with x- and y-axes that are perpendicular to each other, we do not need to use the vector components of $\vec{F}$ but can instead provide the same information about the vector by specifying the **scalar components** F_x and F_y of the force $\vec{F}$. The advantage of the scalar components is that they are numbers with signs, which can be added and subtracted more easily than vector quantities. We are familiar with scalar components from Chapters 2 and 3, but here we will learn how to find scalar components of a vector

FIGURE 4.1 Two routes to get to the same destination.





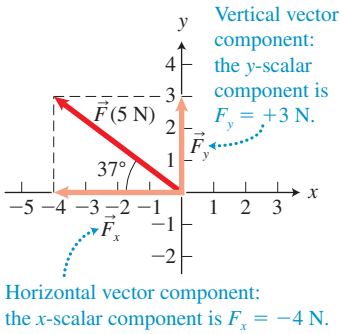


FIGURE 4.2 Graphically adding force components.

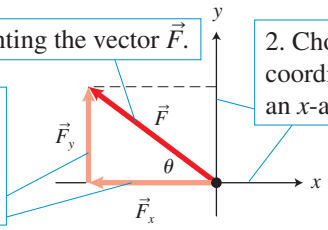
TIP When we replace a vector with the sum of its vector components, we sometimes say that we "resolve" the vector into components.

FIGURE 4.3 The vector and scalar components of a vector.

that makes an angle with a coordinate axis. **Figure 4.3** shows how to find the scalar components of such a force vector. The force $\vec{F}$ is 5 N and points 37° above the negative x-axis. The x-vector component of force $\vec{F}$ is 4 N long and points in the negative x-direction. Thus, the x-scalar component of $\vec{F}$ is $F_x = -4$ N. Similarly, the y-vector component of $\vec{F}$ is 3 N in the positive y-direction—it pulls upward in the positive y-direction. Thus, we can specify the y-scalar component of $\vec{F}$ as $F_y = +3$ N. Thus, the x- and y-components $F_x = -4$ N and $F_y = +3$ N tell us everything we need to know about the force $\vec{F}$. Note that scalars are *not* written with a vector symbol above them.

Finding the scalar components of a force from its magnitude and direction



If we know the magnitude of a force F and the angle θ that the force makes above or below the positive or negative x-axis, we can determine its scalar components. Physics Tool Box 4.1 summarizes how to do this.

PHYSICS TOOL BOX 4.1 **Determining the scalar components of a vector**

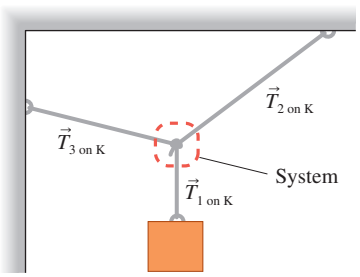
1. Draw an arrow representing the vector $\vec{F}$.

2. Choose and draw perpendicular coordinate axes (e.g., a y-axis and an x-axis).

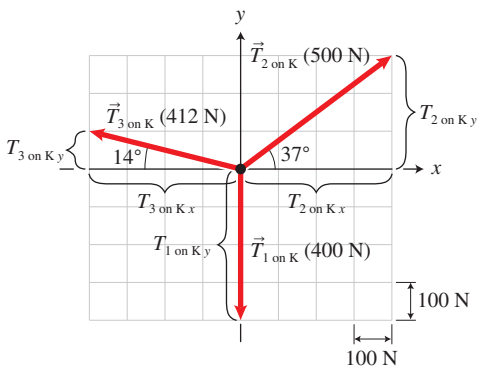
3. Represent the vector $\vec{F}$ as the sum of two perpendicular component vectors $\vec{F}_y$ and $\vec{F}_x$.

4. Finally, use the right triangle and trigonometry to calculate the values of the scalar components:

$$F_x = \pm F \cos\theta \quad (4.1x)$$
$$F_y = \pm F \sin\theta \quad (4.1y)$$



where F is the magnitude of the force vector and θ is the angle (90° or less) that $\vec{F}$ makes with respect to the $\pm x$-axis. F_x is positive if in the positive x-direction and negative if in the negative x-direction. F_y is positive if in the positive y-direction and negative if in the negative y-direction.



Notice that in the figure above, θ is the angle between the vector and the x-axis. If a different angle is given, use your knowledge of trigonometry to determine the components.

TIP Note that the sign (+ or −) of a scalar component depends on the orientation of the corresponding vector component relative to the axis. If the vector component points in the positive direction of the axis, the scalar component is positive. If the vector component points in the negative direction, the scalar component is negative.

QUANTITATIVE EXERCISE 4.1 **Components of forces exerted on a knot**

Three ropes pull on a knot. We draw the force diagram for this situation on a grid so that you can see the components of the three forces that the ropes exert on the knot. Use the diagram to visually determine the x- and y-scalar components of the force that rope 2 exerts on the knot. Then use the mathematical method described in Physics Tool Box 4.1 to calculate the components of this force. The results of using the two methods should be consistent.

Represent mathematically We label the forces that the ropes exert on the knot using the letter T instead of F. This is a common way of noting the forces that ropes or strings exert on an object—tension forces. From the force diagram, we see that rope 2 pulls on the knot at a 37° angle above the positive x-axis, exerting a force of magnitude $T_{2\text{ on K}} = 500$ N. The x-scalar component of this force is +400 N (4 grid units in the positive x-direction) and the y-scalar component of this force is +300 N (3 grid units in the positive y-direction). In symbols, $T_{2\text{ on K}\,x} = +400$ N and $T_{2\text{ on K}\,y} = +300$ N.

Solve and evaluate Now use the mathematical method to calculate the components of the force that rope 2 exerts on the knot:

$$T_{2\text{ on K}\,x} = +(500\text{ N})\cos 37° = +400\text{ N}$$
$$T_{2\text{ on K}\,y} = +(500\text{ N})\sin 37° = +300\text{ N}$$

The diagrammatical and the mathematical methods are consistent.

Try it yourself Use the same two methods to determine the components of the forces exerted by ropes 1 and 3 on the knot.

Answer $T_{3\text{ on K}\,x} = -400$ N and $T_{3\text{ on K}\,y} = +100$ N, and $T_{1\text{ on K}\,x} = 0$ and $T_{1\text{ on K}\,y} = -400$ N.

TIP Be careful when applying Eqs. (4.1x) and (4.1y). The angles that appear in those equations must be measured with respect to the positive or negative x-axis.

REVIEW QUESTION 4.1 When does a vector have a positive scalar component? When does a vector have a negative scalar component?

4.2 Newton's second law in component form

In this section we will apply Newton's second law to more complex situations in which one or more of the forces exerted on the system do not point along one of the coordinate axes. The figure in Quantitative Exercise 4.1 is an example of such a situation. If the knot in that figure is not accelerating, the sum of the forces exerted on the knot is zero:

$$\Sigma\vec{F}_{\text{on K}} = \vec{T}_{1\text{ on K}} + \vec{T}_{2\text{ on K}} + \vec{T}_{3\text{ on K}} = 0$$

It is difficult to use this vector equation to analyze the situation further—for example, to determine one unknown force if you know the other two forces. However, we can do such tasks if this situation is represented in scalar component form.

Notice in the force diagram in Quantitative Exercise 4.1 that the y-scalar components of the forces that the three ropes exert on the knot add to zero. Ropes 2 and 3 exert forces that have positive y-scalar components +300 N + 100 N = +400 N, and rope 1 exerts a force with negative y-scalar component –400 N. Consequently:

$$a_{\text{K}y} = \frac{T_{1\text{ on K}\,y} + T_{2\text{ on K}\,y} + T_{3\text{ on K}\,y}}{m_{\text{K}}} = \frac{-400\text{ N} + 300\text{ N} + 100\text{ N}}{m_{\text{K}}} = 0$$

Similarly, the x-scalar components of the forces exerted on the knot also add to zero:

$$a_{\text{K}x} = \frac{T_{1\text{ on K}\,x} + T_{2\text{ on K}\,x} + T_{3\text{ on K}\,x}}{m_{\text{K}}} = \frac{0 + 400\text{ N} + (-400\text{ N})}{m_{\text{K}}} = 0$$

Thus, we infer that when the x- and y-scalar components of the sum of the forces exerted on the system are zero, it does not accelerate:

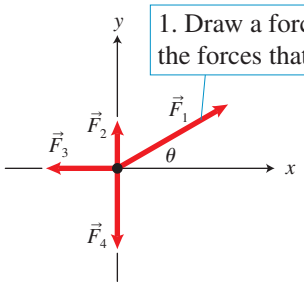
$$a_x = 0 \quad \text{if} \quad \Sigma F_{\text{on K}\,x} = 0$$
$$a_y = 0 \quad \text{if} \quad \Sigma F_{\text{on K}\,y} = 0$$

Suppose that in general objects 1, 2, 3, and so forth exert forces $\vec{F}_{1\text{ on S}}$, $\vec{F}_{2\text{ on S}}$, $\vec{F}_{3\text{ on S}}$, ... on a system and that the forces point in arbitrary directions and do not add to zero. If the system has mass m_S, it has an acceleration $\vec{a}_S$ as a consequence of these forces (Newton's second law):

$$\vec{a}_S = \frac{\vec{F}_{1\text{ on S}} + \vec{F}_{2\text{ on S}} + \vec{F}_{3\text{ on S}} + \cdots}{m_S}$$

Because this equation involves vectors, we can't work with it directly. However, we can split it into its x- and y-scalar component forms to use Newton's second law to determine the system's acceleration.

TIP In practice, we usually choose the axes so that the object accelerates along only one of these axes and has zero acceleration along the other axis.



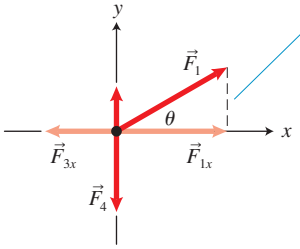
Newton's second law rewritten in scalar component form becomes:

$$a_{Sx} = \frac{F_{1\text{ on S}\,x} + F_{2\text{ on S}\,x} + F_{3\text{ on S}\,x} + \cdots}{m_S} \tag{4.2x}$$

$$a_{Sy} = \frac{F_{1\text{ on S}\,y} + F_{2\text{ on S}\,y} + F_{3\text{ on S}\,y} + \cdots}{m_S} \tag{4.2y}$$

The process of analyzing a situation using Newton's second law in component form is illustrated in Physics Tool Box 4.2. (Note that for convenience we can drop the word *scalar* and use the simpler term *component form*.)

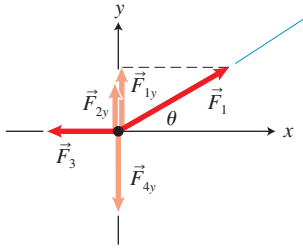
PHYSICS TOOL BOX 4.2 Using Newton's second law in component form



1. Draw a force diagram (the force arrows represent the forces that other objects exert on the system).

2. Visualize the x-components of the forces and apply the x-component form of Newton's second law to the force diagram:

$$a_x = \frac{\Sigma F_x}{m} = \frac{F_{1x} + F_{2x} + F_{3x} + F_{4x}}{m} = \frac{+F_1 \cos\theta + 0 + (-F_3) + 0}{m}$$



Notice that: $F_{1x} = +F_1 \cos\theta$
$F_{2x} = +F_2 \cos 90° = 0$
$F_{3x} = -F_3 \cos 0° = -F_3$
$F_{4x} = +F_4 \cos 90° = 0$

3. Visualize the y-components of the forces and apply the y-component form of Newton's second law to the force diagram:

$$a_y = \frac{\Sigma F_y}{m} = \frac{F_{1y} + F_{2y} + F_{3y} + F_{4y}}{m} = \frac{+F_1 \sin\theta + F_2 + 0 + (-F_4)}{m}$$

Notice that: $F_{1y} = +F_1 \sin\theta$
$F_{2y} = +F_2 \sin 90° = +F_2$
$F_{3y} = -F_3 \sin 0° = 0$
$F_{4y} = -F_4 \sin 90° = -F_4$

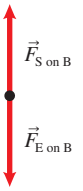
TIP Perhaps the part of this procedure that causes the most difficulty is the construction of the force diagram. Be sure to include in the diagram only forces exerted *on* the system by external objects (outside the system). Do *not* include forces that the system exerts on external objects (objects that are not included in the system).

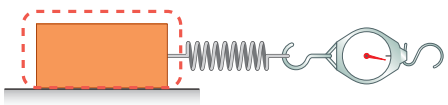
REVIEW QUESTION 4.2 The x- and y-components of Newton's second law for a specific scenario are:

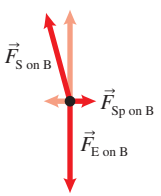
$$x\text{: } 1.0\ \text{m/s}^2 = (60\ \text{N})\cos 30^\circ/(50\ \text{kg})$$
$$y\text{: } 0\ \text{m/s}^2 = (50\ \text{kg}) \times (9.8\ \text{N/kg}) + (60\ \text{N})\sin 30^\circ + (-520\ \text{N})$$

Draw a force diagram for the system and a sketch of a possible scenario.

4.3 Friction

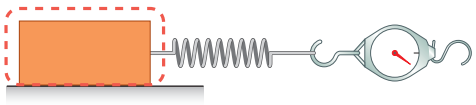


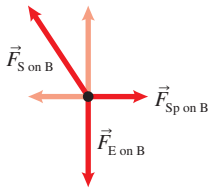


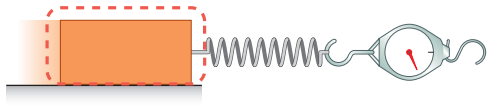


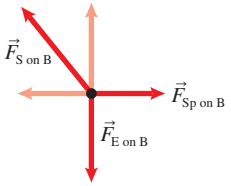
Up to this point, we have assumed that objects move across absolutely smooth surfaces with no friction. In reality, the vast majority of situations involve some degree of friction. In this section we will examine the phenomenon of friction conceptually and construct mathematical models that allow us to take friction into account quantitatively.

Static friction







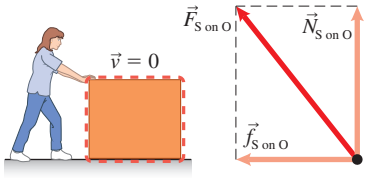


Consider a simple experiment as shown in Observational Experiment **Table 4.1**. A spring scale exerts an increasing force on the block. Observe carefully what happens to the block.

OBSERVATIONAL EXPERIMENT TABLE 4.1  **Pulling a block with a spring scale**

VIDEO OET 4.1

Observational experiment	Analysis
A block is at rest on the horizontal surface of a desk. 	The force diagram for the block is shown at right. 
A spring scale pulls lightly on the block; the block does not move. 	The pulling force $\vec{F}_{\text{Sp on B}}$ is exerted parallel to the surface and $\vec{F}_{\text{E on B}}$ is perpendicular to the surface. Because the block is not accelerating, the sum of all forces exerted on it must be zero. We therefore conclude that the surface exerts a force $\vec{F}_{\text{S on B}}$ that, when added to the two forces above, gives zero. The vector component of this force perpendicular to the surface has the same magnitude as $\vec{F}_{\text{E on B}}$; its component parallel to the surface has the same magnitude as $\vec{F}_{\text{Sp on B}}$. 



(CONTINUED)

Observational experiment	Analysis
The spring scale pulls harder on the block; the block still does not move. 	The perpendicular component of $\vec{F}_{\text{S on B}}$ stays the same; the magnitude of the parallel vector component increases. Therefore, the direction of $\vec{F}_{\text{S on B}}$ changes, too. 
The spring scale pulls even harder on the block; the block finally starts moving. 	The force diagram for the moment just before the block begins moving is shown at right. 

Patterns

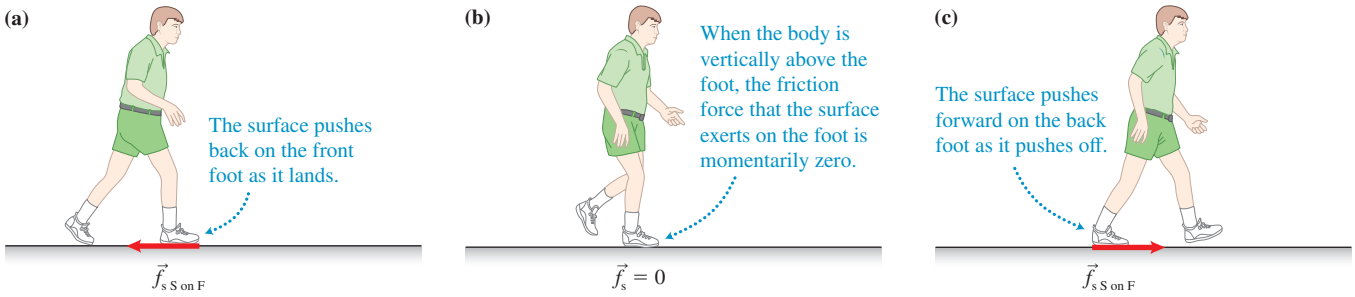
- In each of the experiments, the surface exerted a force on the block that can be resolved into two vector components—one perpendicular to the surface and one parallel to it.
- The perpendicular component of $\vec{F}_{\text{S on B}}$ did not change with the increase of the pulling force, but the parallel component did. The parallel component seems to represent resistance to the motion of the block.
- The magnitude of the parallel component (the resistive force) can only increase up to a certain value. Thus the resistive force must be variable and have a maximum value.

FIGURE 4.4 The force that the surface exerts on an object.

The force that the surface exerts on the block is the sum of two vector components: the normal force $\vec{N}$ and the friction force $\vec{f}$.

TIP To simplify force notation in problem solving, we will use the symbol $\vec{N}_{\text{S on O}}$ for the normal force, $\vec{f}_{\text{s S on O}}$ for the static friction force, and $\vec{f}_{\text{k S on O}}$ for the kinetic friction force exerted by the surface on the object.

The patterns that we found in Table 4.1 allow us to make two important conclusions. First, we can always resolve the force that a surface exerts on an object into two vector components (see **Figure 4.4**):



1. the component perpendicular to the surface, which we will call the **normal force** (a *normal* line in geometry means a line perpendicular to a particular surface), and
2. the component parallel to the surface, which we will call the **friction force**.

Second, we can infer that if you place an object on a surface, and you pull on the object in an attempt to get it to slide across the surface, the friction component of the force that the surface exerts on the object is in the opposite direction to the pulling force so that the object does not begin to move. The friction force exerted on a stationary object is called the **static friction force**. It can vary in strength up to a maximum value. When the external force exerted on the object exceeds this maximum force, the object starts moving. This maximum resistive force that the surface can exert on the object is called the **maximum static friction force**. Once the object starts moving, we call the friction component of the force that the surface exerts on the object the **kinetic friction force**.

In some applications, such as car engines and bicycle chains, friction should be minimized. However, sometimes friction is a necessary phenomenon. For instance, walking on a flat horizontal sidewalk would not be possible if there were no static friction (**Figure 4.5a**). When one foot swings forward and contacts the sidewalk, static friction prevents it from continuing forward and slipping (the way it might on ice).

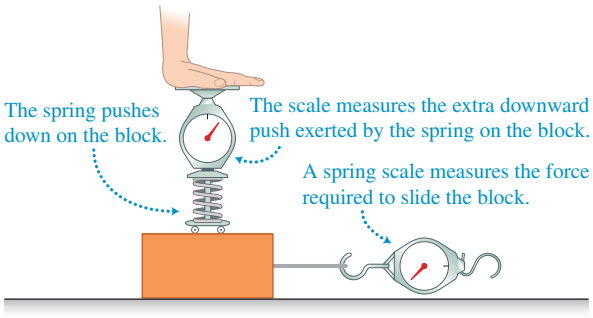
When your body is vertically above the foot, the friction force that the sidewalk exerts on your foot is momentarily zero (Figure 4.5b). As your body gets ahead of the back foot, the foot has a tendency to slip backward. However, the static friction force that the sidewalk exerts on your foot now points opposite that slipping direction, that is, forward, in the direction of motion (Figure 4.5c). As long as this foot does not slip, the surface continues exerting a forward static friction force on you, helping your body move forward.

FIGURE 4.5 The surface exerts a static friction force that helps you walk or run.

What determines the magnitude of the maximum static friction force? To investigate this question, we use an experimental setup in Observational Experiment **Table 4.2** similar to that used in Observational Experiment Table 4.1, except that we will vary the characteristics of the block and the surfaces.

OBSERVATIONAL EXPERIMENT TABLE 4.2 What affects the maximum static friction force?

VIDEO OET 4.2



Observational experiment	Analysis
Experiment 1. ***Changes in the smoothness of the surfaces*** We'll use the spring to pull a smooth plastic block that is resting on three different surfaces: (1) a glass tabletop, (2) a wood tabletop, and (3) a rubber exercise mat. The reading of the spring scale just before the block starts moving is largest for the rubber mat, next largest for the wood tabletop, and smallest for the glass tabletop.	$\vec{f}_{s\,R\text{ on }B} > \vec{f}_{s\,W\text{ on }B} > \vec{f}_{s\,G\text{ on }B}$
Experiment 2. ***Changes in the surface area*** We vary the size of contact area between the block and the rubber mat. The block is shaped like a brick and has faces of three different areas. We use the spring to pull the block while it is resting on each of these three different faces. The reading of the scale just before the block starts to move is the same for all three areas.	$\vec{f}_{s\,R\text{ on }BA1} = \vec{f}_{s\,R\text{ on }BA2} = \vec{f}_{s\,R\text{ on }BA3}$
Experiment 3. ***Changes in the mass of the block*** We take plastic blocks of 1.0 kg, 2.0 kg, and 3.0 kg and place them all on the same wood tabletop. We use a spring scale to pull each of them. The reading of the scale just before the blocks start moving is smallest for the 1.0-kg block, twice as large for the 2.0-kg block, and three times as large for the 3.0-kg block.	$\vec{f}_{s\,W\text{ on }3\text{ kg }B} = 3\vec{f}_{s\,W\text{ on }1\text{ kg }B}$ $\vec{f}_{s\,W\text{ on }2\text{ kg }B} = 2\vec{f}_{s\,W\text{ on }1\text{ kg }B}$ The maximum static friction force that the tabletop exerts on the block is directly proportional to the mass of the block.
Patterns	
The maximum static friction force that the surface can exert on the block depends on the roughness of the contacting surfaces and the mass of the block, but does not depend on the area of contact between the surfaces.	

The patterns in Table 4.2 make testable hypotheses. To test a hypothesis, we need to design an experiment in which we can vary one of the properties and make a prediction of the outcome based on the hypothesis being tested. We will test one hypothesis in Testing Experiment **Table 4.3** (on the next page), that the maximum static friction force is directly proportional to the mass of the object.

TESTING
EXPERIMENT TABLE 4.3 Does the maximum static friction force depend on mass?

VIDEO TET 4.3

Testing experiment	Prediction	Outcome
We use a string attached to a spring scale to pull a 1-kg block. The mass of the block does not change, but we push down on the block with a spring that exerts a series of downward forces on it. For each of these downward forces, we use the pulling string and spring scale to determine the maximum static friction force the surface exerts on the block. The downward pushing spring is on wheels to prevent it from exerting horizontal forces on the block.	If the friction force is proportional to the mass of the block, the friction force should remain constant during the experiment.	The friction force changes—the harder we press on the block, the higher the maximum static friction force.

Conclusion

The outcome of the experiment did not match the prediction; the hypothesis requires a revision.

Pulling vs. pushing Pulling a sled on snow is easier than pushing it. When we pull the sled, we lift it up slightly, decreasing the force that the sled exerts on the snow. Therefore, the force exerted by the snow on the sled decreases, too (both the perpendicular to the snow component and the parallel component).

The outcome of the testing experiment in Table 4.3 is not unexpected. Pushing down on the block perpendicularly to the surface increases the force that the block exerts on the surface, and according to Newton's third law, the surface therefore exerts a greater force on the block. Remember that the friction force is just the component parallel to the surface of the force that the surface exerts on the object; the other component of that same force is the normal force. Therefore, we expect these two components to be related. Table 4.4 shows the relationship between the normal force and maximum static friction force for our experiment in Table 4.3.

From the data in Table 4.4 we find a new pattern. The ratio of the maximum static friction force to the normal force

$$\frac{f_{\text{s S on O max}}}{N_{\text{S on O}}} \approx 0.31$$

and is about the same (within experimental uncertainty) for all the measurements (the last column in the table). It appears that **the maximum static friction force is directly proportional to the magnitude of the normal force**: $f_{\text{s S on O max}} \propto N_{\text{S on O}}$. This finding makes sense if you look back at Figure 4.4. If the normal force exerted by the surface on an object increases, the maximum static friction force the surface exerts on the object increases proportionally.

TABLE 4.4 Maximum static friction force when a block presses harder against a surface

Mass of the block	Extra downward force exerted on the 1-kg block	Normal force exerted by the surface on the block	Maximum static friction force	Ratio of maximum static friction force to normal force
1.0 kg	0.0 N	9.8 N	3.0 N	0.31
1.0 kg	5.0 N	14.8 N	4.5 N	0.30
1.0 kg	10.0 N	19.8 N	6.1 N	0.31
1.0 kg	20.0 N	29.8 N	9.1 N	0.31

If we repeat the Table 4.4 experiments using a different type of block on a different surface, we get similar results. The ratio of the maximum friction force to the normal force is the same for all the different values of the normal forces. However, the proportionality constant depends on the contacting surfaces: it is greater for rough surfaces and smaller for smoother surfaces.

This ratio

$$\mu_s = \frac{f_{s\,S\text{ on }O\,max}}{N_{S\text{ on }O}}$$

is called the **coefficient of static friction** μ_s for a particular pair of surfaces. The coefficient of static friction is a measure of the relative difficulty of sliding two surfaces across each other. The easier it is to slide one surface on the other, the smaller the value of μ_s. You experience different values of μ_s when you try to walk on ice and on rough snow. Where are you more likely to slide?

The coefficient of static friction μ_s has no units because it is the ratio of two forces. Although μ_s usually has values between 0 and 1, it can be greater than 1. Its value is about 0.8 for rubber car tires on a dry highway surface and is very small for bones in healthy body joints separated by cartilage and synovial fluid. Some values for different surfaces are listed in **Table 4.5**.

Static friction force When two objects are in contact and we try to move one across the other, they exert forces on each other. The components of these forces parallel to the surface are static friction forces, which oppose the tendency of the objects to move with respect to each other. Static friction force is exerted on both objects, but we are usually concerned with one of them, which we call the system (**Figure 4.6**). The static friction force changes magnitude to prevent motion of the system—up to a maximum value. This maximum static friction force depends on the roughness of the surfaces of the two objects (on the coefficient of static friction μ_s between the surfaces) and it is related to the magnitude of the normal force N exerted by one surface on the other. That is due to the fact that the friction force and normal force are two perpendicular vector components of the same force that the surface exerts on the system. The magnitude of the static friction force is always less than or equal to the product of these two quantities:

$$0 \leq f_{s\,S\text{ on }O} \leq \mu_s N_{S\text{ on }O} \qquad (4.3)$$

Keep in mind the assumptions we used when constructing this model of friction. We used relatively light objects resting on relatively firm surfaces. The objects never caused the surfaces to deform significantly (for example, it was not a car tire sinking into mud). Equation (4.3) is only reasonable in situations in which these conditions hold.

FIGURE 4.6 Force analyses when we choose different objects as the system.

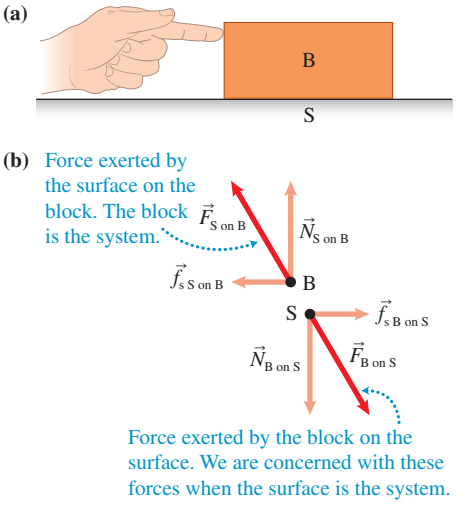


TABLE 4.5 The coefficients of kinetic and static friction between two surfaces

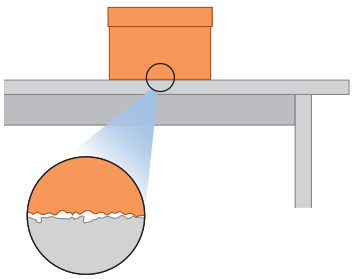
Contacting surfaces	Coefficient of static friction μ_s	Coefficient of kinetic friction μ_k
Rubber on concrete (dry)	1	0.6–0.85
Steel on steel	0.74–0.78	0.42–0.57
Aluminum on steel	0.61	0.47
Glass on glass	0.9–1	0.4
Wood on wood	0.25–0.5	0.20
Waxed skis on wet snow	0.14	0.1
Teflon on Teflon	0.04	0.04
Greased metals	0.1	0.06
Surfaces in a healthy human joint	0.01	0.003

Kinetic friction

If we repeat the previous friction experiments with a block that is already in motion, we find a similar relationship between the resistive friction force exerted by the surface on the block and the normal force exerted by the surface on the block. There are, however, two differences: (1) under the same conditions, the magnitude of the kinetic friction force is always lower than the magnitude of the maximum static friction force (see Table 4.5), and (2) the resistive force exerted by the surface on the moving object does not vary but has a constant value. As with the static friction force $\vec{f}_s$, the magnitude of the kinetic friction force f_k depends on the roughness of the contacting surfaces (indicated by a **coefficient of kinetic friction** μ_k) and on the magnitude N of the normal force exerted by one of the surfaces on the other, but not on the surface area of contact. The word *kinetic* indicates that the surfaces in contact are moving relative to each other.



Kinetic friction force When an object slides along a surface, the components of the forces parallel to the surface that the surface exerts on the object are called kinetic friction forces. These forces oppose the motion of the object. The kinetic friction force depends on the surfaces themselves (on the coefficient of kinetic friction μ_k) and relates to the magnitude of the normal force component N of the total force that the surface exerts on the moving object as

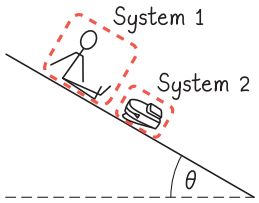
$$f_{k\,S\text{ on }O} = \mu_k N_{S\text{ on }O} \tag{4.4}$$

As with any mathematical model, this expression for kinetic friction has its limitations. First, it is applicable only for sliding objects, not rolling objects. Second, it has the same assumption about the rigidity of the surfaces as the model for static friction. Third, predictions based on Eq. (4.4) fail for objects moving at high speed. Although this equation does not have general applicability, it is simple and useful for rigid surfaces and everyday speeds.

What causes friction?

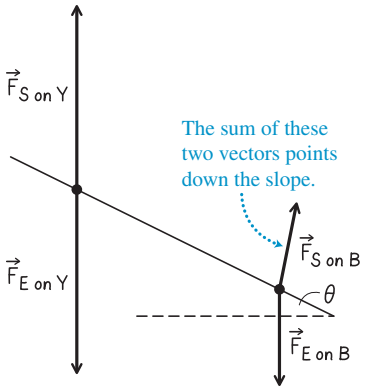
FIGURE 4.7 A microscopic view of contacting surfaces.

Rough edges on the contacting surfaces cause friction.

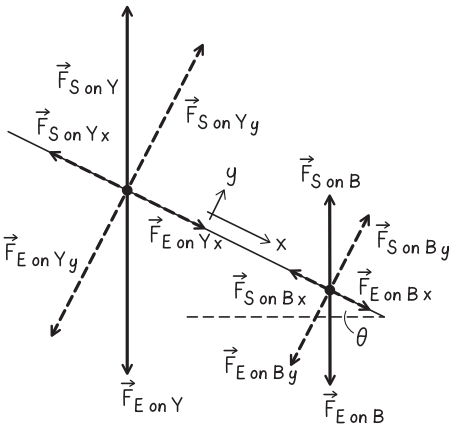


Let's use the example of Velcro fastening material to help understand the phenomenon of friction. The hooks and loops on the two surfaces of Velcro connect with each other, making it almost impossible to slide one surface across the other. All objects are, in a less dramatic way, like Velcro. Even the slickest surfaces have tiny bumps that can hook onto the tiny bumps on another surface (**Figure 4.7**). Logically, smoother surfaces should have reduced friction. For example, a book with a glossy cover slides farther across a table than a book with a rough, unpolished cover. The friction force exerted by the table on the glossy book is smaller than that on the other book.

However, if the surfaces are too smooth (for example, two polished metal blocks), the friction increases again. Why? All substances are made of microscopic particles that are attracted to each other. This attraction keeps a solid object in whatever shape it has. But this attraction between particles works only at very short distances. If two surfaces are so smooth that the microscopic particles are close enough to attract each other strongly (almost close enough to form chemical bonds with each other), it becomes more difficult to slide one surface over the other (for example, two pieces of plastic wrap or two polished metal blocks).

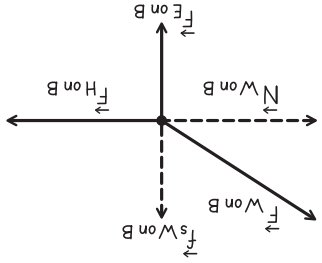


CONCEPTUAL EXERCISE 4.2 **Sitting on a slope**



You decide to have a picnic on a grassy slope that makes an angle θ with the horizontal. You sit down and put your backpack on the grass, only to find that it starts to slide down the slope. Draw force diagrams for you and the backpack, and use them to explain why you do not start sliding but your backpack does.

Sketch and translate We draw a sketch of the situation and mark the angle of the slope with the horizontal on it. We choose two different systems, you and the backpack. We orient the coordinate axes so that the x-axis is parallel to the slope and the y-axis is perpendicular. This strategy is commonly used in inclined plane problems.



Simplify and diagram We assume that both you and the backpack can be considered point-like. There are two external objects interacting with both systems—Earth and the grassy slope. Because you are not accelerating, the forces exerted by these two objects on you ($\vec{F}_{\text{E on Y}}$ and $\vec{F}_{\text{S on Y}}$) must add to zero, while the sum of the forces exerted on the backpack ($\vec{F}_{\text{E on B}}$ and $\vec{F}_{\text{S on B}}$) must point down the slope, as shown in the left-hand figure at the top of the next column. The force that the slope exerts on both systems can be resolved into two components with respect to the slope's surface—the normal force and the static friction force. The force that Earth exerts on you can also be resolved into two vectors. Because neither object is accelerating along the y-axis, the normal force and the y-component of the force that Earth exerts on the system must be equal in magnitude. We also see that if the y-component of the force that Earth exerts on the system is greater than the maximum friction force, the system will accelerate down the slope. This is exactly what happens to the backpack.

Try it yourself You press a book horizontally against a vertical wall so that the book is not sliding. Draw a force diagram for the book and indicate the magnitude and direction of the normal force and the static friction force components.

Answer

The magnitude of the static friction force is equal to the mass of the book times the gravitational coefficient. The magnitude of the normal force is thus $N_{\text{W on B}} = \frac{f_{\text{s W on B}}}{\mu_s} = \frac{mg}{\mu_s}$. Note that if the coefficient of friction is small, the force you have to exert on the book to keep it from sliding down the wall is much larger than the force needed to hold the book in your hand.

Other types of friction

There are other types of friction besides static and kinetic friction, such as *rolling friction*. Rolling friction is caused by the surfaces of rolling objects indenting slightly as they turn. This friction is decreased in tires that have been inflated to a higher pressure. In a later chapter (Chapter 14) we will learn about another type of friction, the friction that air or water exerts on a solid object moving through the air or water—a so-called *drag force*.

TIP From now on we will treat the normal component and the friction component of the force that the surface exerts on an object as two different forces.

REVIEW QUESTION 4.3 What is the force of friction that the floor exerts on your refrigerator? Assume that the mass of the refrigerator is 100 kg, the coefficient of kinetic friction is 0.30, and the coefficient of static friction is 0.35. What assumptions did you make in answering this question?

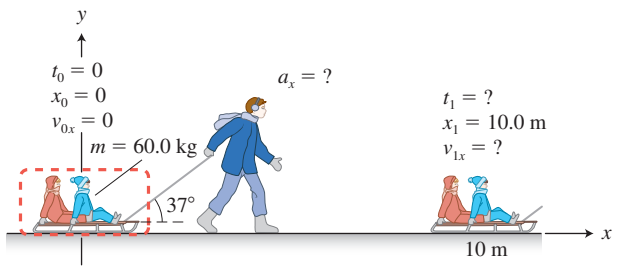
4.4 Skills for analyzing processes involving forces in two dimensions

Our analysis of processes in this and the previous chapter often involves the application of both Newton's second law and kinematics equations, thus relating the external forces exerted on an object and its changing motion. Below we describe a general method for analyzing processes that involve forces in two dimensions and illustrate its use for a simple example of pulling a sled.

PROBLEM-SOLVING STRATEGY 4.1 Analyzing processes involving forces in two dimensions

Sketch and translate

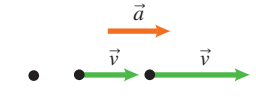
- Make a sketch of the process.
- Choose a system.
- Choose coordinate axes with one axis in the direction of acceleration and the other axis perpendicular to that direction.
- Indicate in the sketch everything you know about the process relative to these axes.
- Identify the unknown quantity of interest.



Simplify and diagram

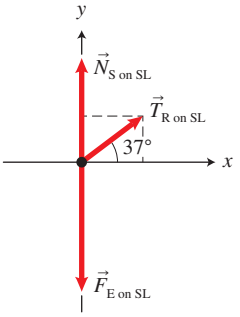
- Simplify the process. For example, can you model the system as a point-like object? Can you ignore friction?
- Represent the process diagrammatically with a motion diagram and a force diagram.
- Check for consistency of the diagrams—is the sum of the forces in the direction of the acceleration?

EXAMPLE 4.3 Pulling a sled



You pull a sled across a hard snowy surface. The sled and the two children sitting on it have a total mass of 60.0 kg. The rope you pull exerts a 100-N force on the sled and is oriented 37° above the horizontal. If the sled starts at rest, how fast is it moving after being pulled 10.0 m?

We first sketch the process. Choose the sled and children as the system. The process starts with the sled at rest ($v_{0x} = 0$) and ends when it has traveled $x_1 - x_0 = 10.0$ m and has an unknown final speed v_{1x}. Thus the sled is accelerating.



Consider the system as a point-like object. Since we have no information about friction, assume its effects on the sled are insignificant, and thus the snow only exerts a force perpendicular to its surface.

A motion diagram for the sled is shown at right. The sled moves at increasing speed toward the right.

Draw a force diagram for the system. Earth exerts a downward gravitational force on the system $\vec{F}_{\text{E on SL}}$, the rope pulls on the sled $\vec{T}_{\text{R on SL}}$ at a 37° angle above the horizontal, and the snow exerts a normal force on the sled perpendicular to the surface (in this case upward) $\vec{N}_{\text{S on SL}}$. Because the sled does not accelerate vertically, the y-components of the forces should add to zero; therefore, the length of the arrow for the force that the snow exerts on the sled is shorter than the arrow for the force that Earth exerts on the sled. The vertical component of the pulling force adds to the force exerted by the snow to balance the force exerted by Earth.

Are the diagrams consistent? The sum of the forces is toward the right in the direction of the acceleration. The vertical force components add to zero.

Represent mathematically

- Convert these qualitative representations into quantitative mathematical descriptions of the process using Newton's second law and kinematics equations.

The horizontal x-component form of Newton's second law is

$$ma_x = \Sigma F_x$$
$$m_{SL}a_x = T_{R\text{ on }SL\,x} + N_{S\text{ on }SL\,x} + F_{E\text{ on }SL\,x}$$

Substitute expressions for the x-components of these three forces:

$$m_{SL}a_x = T_{R\text{ on }SL}\cos 37^\circ + N_{S\text{ on }SL}\cos 90^\circ + F_{E\text{ on }SL}\cos 90^\circ$$

Noting that $\cos 90^\circ = 0$ and dividing both sides by the mass of the sled with the children, we find that

$$a_x = \frac{T_{R\text{ on }SL}\cos 37^\circ + 0 + 0}{m_{SL}}$$

We could at this point use the y-component equation to find the magnitude of the normal force that the surface exerts on the sled, but we don't need to do that to answer the question.

The above equation can be used to determine the sled's acceleration. We are then left with a kinematics problem to determine the speed v_{1x} of the sled after pulling it for $x_1 - x_0 = 10.0$ m. We can use kinematics Eq. (2.7):

$$v_{1x}^2 = v_{0x}^2 + 2a_x(x_1 - x_0)$$

Solve and evaluate

- Substitute the given values into the mathematical expressions and solve for the unknowns.
- Decide whether the assumptions that you made were reasonable.
- Finally, evaluate your work to see if it is reasonable (check units, limiting cases, and whether the answer has a reasonable magnitude).
- Make sure the answer is consistent with other representations.

The acceleration is

$$a_x = \frac{+T_{R\text{ on }SL}\cos 37^\circ}{m_{SL}} = \frac{+(100\text{ N})(\cos 37^\circ)}{60.0\text{ kg}} = +1.33\text{ m/s}^2$$

The speed of the sled after being pulled for 10.0 m will be

$$v_{1x}^2 = v_{0x}^2 + 2a_x(x_1 - x_0) = 0^2 + 2(1.33\text{ m/s}^2)(10.0\text{ m} - 0)$$

or

$$v_{1x} = 5.2\text{ m/s}$$

This is fast but not unreasonable. In real life, friction between the sled and the snow would probably cause the speed to be slower. The units are correct. If we examine a limiting case, in which the rope pulls vertically, the horizontal acceleration is zero, as it should be.

Try it yourself (a) Determine the y-component of the gravitational force that Earth exerts on the sled-children system. (b) Then determine the y-component of the force that the rope exerts on the system. (c) Finally, use the y-component form of Newton's second law to determine the y-component of the normal force that the snow exerts on the sled.

Answers

(a) $F_{E\text{ on }SL,y} = -m_{SL}g\sin 90^\circ = -590$ N; (b) $T_{R\text{ on }SL,y} = +T_{R\text{ on }SL}\sin 37^\circ = +60$ N; (c) $N_{S\text{ on }SL,y} = +530$ N.

Looking at the force diagram, we see that these numbers make sense. Why is the magnitude of the normal force less than $m_{SL}g$?

Processes involving friction

When solving problems involving friction, remember that the friction force is a vector component parallel to the surface of the force that the surface exerts on an object. The component of the same force perpendicular to the surface is the normal force.

EXAMPLE 4.4 Equation Jeopardy

The equations below are the horizontal x- and vertical y-component forms of Newton's second law applied to a physical process. Solve for the unknown quantities. Then work backward and construct a force diagram for the system of interest and invent a process and question for which the equations might provide an answer (there are many possibilities). Remember that the italicized N is the symbol for normal force, and the roman N is a symbol for the newton.

x-component equation:

$$(200\text{ N})\cos 30^\circ + 0 - 0.40N_{\text{S on O}} + 0 = (50\text{ kg})a_x$$

y-component equation:

$$(200\text{ N})\sin 30^\circ + N_{\text{S on O}} + 0 - (50\text{ kg})(9.8\text{ N/kg}) = (50\text{ kg})0$$

Solve Inserting the cosine and sine values, we get:

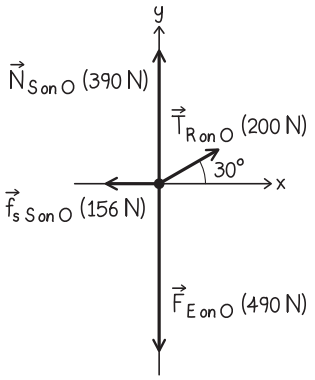
x-component equation:

$$(200\text{ N})0.87 + 0 - 0.40N_{\text{S on O}} + 0 = (50\text{ kg})a_x$$

y-component equation:

$$(200\text{ N})0.50 + N_{\text{S on O}} + 0 - (50\text{ kg})(9.8\text{ N/kg}) = 0$$

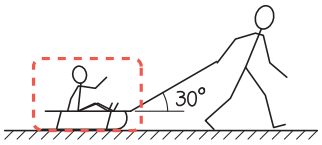
We can solve the y-equation for the magnitude of the normal force: $N_{\text{S on O}} = 390$ N. Inserting this value into the x-equation produces the following:



$$(200\text{ N})0.87 + 0 - 0.40(390\text{ N}) + 0 = (50\text{ kg})a_x$$

This can now be solved for a_x:

$$\begin{aligned} a_x &= (174\text{ N} - 156\text{ N})/(50\text{ kg}) \\ &= +0.36\text{ N/kg} = +0.36\text{ m/s}^2 \end{aligned}$$

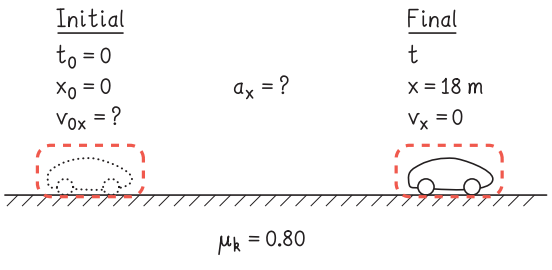


Simplify and diagram The equations provide the components for each of the four forces exerted on the system (since there are four terms on the left side of each equation). Consider the x- and y-scalar components of each force:

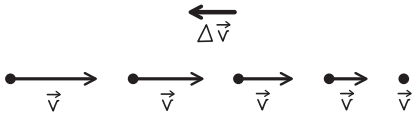
1. A 200-N force oriented 30° above the positive x-axis—maybe a rope is exerting a force on an object.
2. A 390-N normal force points along the y-axis, perpendicular to a surface.
3. It looks like a friction force of $0.40(390\text{ N}) = 156$ N points in the negative x-direction with a coefficient of friction equal to 0.40.
4. A 490-N gravitational force points in the negative y-direction perpendicular to the surface.

We can now use these forces to construct a force diagram.

Sketch and translate The situation could involve a sled or wagon or crate that is being pulled along a horizontal surface, as shown below. Note that the rope is at an angle with respect to the horizontal, so the force that it exerts has a +100-N y-component. It combines with the normal force's +390-N y-component to balance the gravitational force's −490-N y-component.

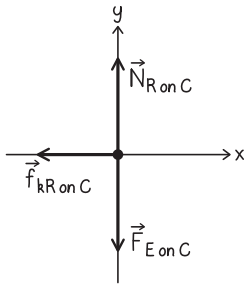


One possible problem statement Determine the acceleration of a 50-kg sled being pulled across a horizontal surface by a rope oriented 30° above the horizontal and pulling with a force of 200 N. The coefficient of kinetic friction between the sled and the surface is 0.40.



EXAMPLE 4.5 Was the car speeding?

A car involved in a minor accident left 18.0-m skid marks on a horizontal road. After inspecting the car and the road surface, a police officer decided that the coefficient of kinetic friction was 0.80. The speed limit on that street is 15.6 m/s (35 mi/h). Was the car speeding?



Sketch and translate We first sketch the process (see the figure at top right). We choose the car as the system. Earth is the object of reference. The coordinate system consists of a horizontal x-axis pointing in the direction of the velocity and a vertical y-axis pointing upward.

Simplify and diagram Assume that the car can be modeled as a point-like object, that its acceleration while stopping was constant, and that the resistive force exerted by the air on the car is small compared with the other forces exerted on it. We sketch a motion diagram for the car at right.

Our force diagram at right shows three forces exerted on the car. Earth exerts a downward gravitational force on the car $\vec{F}_{\text{E on C}}$, the road exerts an upward normal force on the car $\vec{N}_{\text{R on C}}$ (perpendicular to the road surface), and the road also exerts a backward kinetic friction force on the car $\vec{f}_{\text{k R on C}}$ (parallel to the road's surface and opposite the car's velocity). This friction force causes the car's speed to decrease.

Represent mathematically Use the force diagram as shown above to apply Newton's second law in component form. Use the expression for the kinetic friction force ($f_{\text{k R on C}} = \mu_{\text{k}} N_{\text{R on C}}$), the expression for the gravitational force ($F_{\text{E on C}} = m_{\text{C}} g$), and one of the kinematics equations. The car remains in contact with the road surface, so the y-component of its acceleration a_y is zero.

y-component equation:

$$0 = N_{\text{R on C}\,y} + F_{\text{E on C}\,y} + f_{\text{k R on C}\,y}$$

$$0 = N_{\text{R on C}} \sin 90^\circ - m_{\text{C}} g \sin 90^\circ + f_{\text{k R on C}} \sin 0^\circ$$

Note that $\sin 90^\circ = 1.0$ and $\sin 0^\circ = 0$. Thus,

$$N_{\text{R on C}} = m_{\text{C}} g$$

The magnitude of the kinetic friction force is thus

$$f_{\text{k R on C}} = \mu_{\text{k}} N_{\text{R on C}} = \mu_{\text{k}} m_{\text{C}} g$$

x-component equation:

$$m_{\text{C}} a_x = N_{\text{R on C}\,x} + F_{\text{E on C}\,x} + f_{\text{k R on C}\,x}$$
$$= N_{\text{R on C}} \cos 90^\circ + m_{\text{C}} g \cos 90^\circ - f_{\text{k R on C}} \cos 0^\circ$$

Substitute $\cos 90^\circ = 0$ and $\cos 0^\circ = 1.0$ into the above to get

$$m_{\text{C}} a_x = -f_{\text{k R on C}}$$

Combine the two equations for $f_{\text{k R on C}}$ to get

$$m_{\text{C}} a_x = -\mu_{\text{k}} m_{\text{C}} g$$

or

$$a_x = -\mu_{\text{k}} g$$

Now use kinematics to determine the car's velocity v_{0x} before the skid started:

$$v_x^2 - v_{0x}^2 = 2a_x(x - x_0)$$

Solve and evaluate The car's acceleration while stopping was

$$a_x = -\mu_{\text{k}} g = -(0.80)(9.8\ \text{m/s}^2) = -7.84\ \text{m/s}^2$$

We use the kinematics equation $0^2 - v_{0x}^2 = 2a_x(x - x_0)$ to determine the initial speed of the car before the skid started (recall that the final speed $v_x = 0$ and that the stopping distance was 18 m):

$$0^2 - v_{0x}^2 = 2a_x(x - x_0) = 2(18\ \text{m} - 0)(-7.84\ \text{m/s}^2)$$
$$= -282\ \text{m}^2/\text{s}^2 = -(16.8\ \text{m/s})^2$$

$$\Rightarrow v_{0x} = 16.8\ \text{m/s}$$
$$= 16.8\ \text{m/s}(3600\ \text{s/h})(1\ \text{mi}/1609\ \text{m})$$
$$= 38\ \text{mi/h}$$

This is slightly over the 15.6 m/s (35 mi/h) speed limit, but probably not enough for a speeding conviction. Note also that the answer had the correct units.

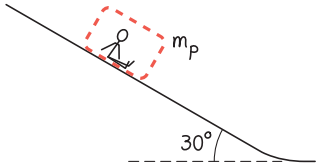
Try it yourself Describe a process that can be represented with the following equations:

$$0 = N_{\text{R on C}} - m_{\text{C}} g;\ a_x = -\mu_{\text{k}} g;\ 0^2 - v_{\text{i}x}^2 = 2(x - x_{\text{i}})a_x$$

Answer

A car is skidding to a stop to avoid a collision.

This method of determining whether a car was speeding before an accident is used in real life. Police officers use the length of skid marks to estimate the speed of a vehicle at the time the driver applied the brakes. Police stations have charts listing the kinetic friction coefficients of various brands of car tires on different types of road surfaces.

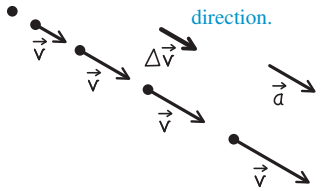


Processes involving inclines

Processes involving inclines are common. For example, a skier skis down a slope or a wagon is pulled uphill. How do we use the component form of Newton's second law and kinematics to analyze such processes?

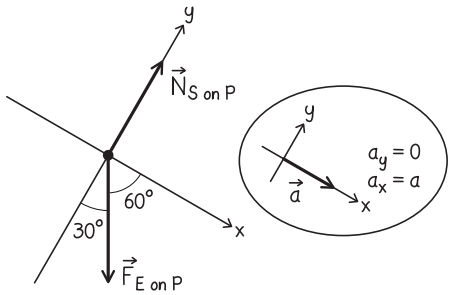
EXAMPLE 4.6 **Who wins a waterslide race?**

A child of mass m and an adult of mass $4m$ simultaneously start to slide from the top of a waterslide that has a downward slope of 30° relative to the horizontal. Which person reaches the bottom first?



Sketch and translate We can choose either the child or the adult as the system. Our sketch shows the person at one moment during the downhill slide and includes the known information. The person who has the greater acceleration along the slide will win the race, so we will construct an expression for the

(CONTINUED)



person's acceleration and see how that acceleration depends on the person's mass. The object of reference is Earth. We choose the axes later when constructing the force diagram.

Simplify and diagram The person is modeled as a point-like object. Since a waterslide is very smooth and slippery, we assume that we can disregard the friction force exerted by the slide on the person.

Next, we build a motion diagram for the person, as shown to the right. The velocity arrows are parallel to the slide, and the person's velocity is increasing, so the velocity change arrow $\Delta\vec{v}$ (and the acceleration $\vec{a}$) points down the slide.

A force diagram shows that Earth exerts a downward gravitational force $\vec{F}_{\text{E on P}}$ on the person and the slide exerts a normal force $\vec{N}_{\text{S on P}}$ on the person perpendicular to the surface. We choose the x-axis parallel to the inclined surface and the y-axis perpendicular to the inclined surface. With this choice, the acceleration points in the positive x-direction. If we had chosen the standard horizontal and vertical directions for our coordinate axes, then the acceleration would have nonzero x- and y-components, making the situation more difficult to analyze.

Represent mathematically The motion of the person is along the x-axis. Use the force diagram to apply the x-component form of Newton's second law:

$$m_{\text{P}}a_x = F_{\text{E on P}\,x} + N_{\text{S on P}\,x}$$

The slide is inclined at 30° relative to the horizontal. This means that the gravitational force makes a 60° angle relative to the slide (and therefore relative to the x-axis, as shown in the diagram). We can calculate the x-component of the gravitational force in two ways: $F_{\text{E on P}\,x} = m_{\text{P}}g\cos 60°$ or $F_{\text{E on P}\,x} = m_{\text{P}}g\sin 30°$. The methods give the same result. The component equation becomes

$$m_{\text{P}}a_x = +(m_{\text{P}}g)\cos 60° + N_{\text{S on P}}\cos 90°$$

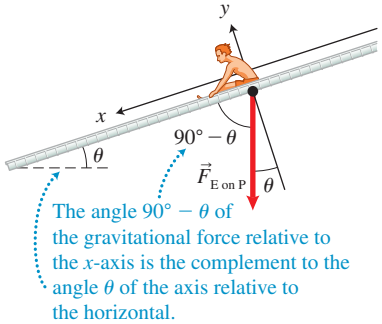
Solve and evaluate Substituting $\cos 90° = 0$, we get

$$m_{\text{P}}a_x = +(m_{\text{P}}g)\cos 60° + 0$$

Dividing by the m_{P} on each side of the equation, we get $a_x = g\cos 60°$. The person's acceleration is independent of her/his mass! Thus, the acceleration of the child and that of the adult are the same. If they start at the same time at the same position, both initially at rest, and have the same acceleration, they arrive at the bottom at the same time. The race is a tie (see the photo).

Try it yourself Suppose that the same child and adult slide down the same waterslide, but this time do not assume that the slide is frictionless. If they wear swimming trunks made of the same material, who will win the race? Explain your prediction and list assumptions.

Answer



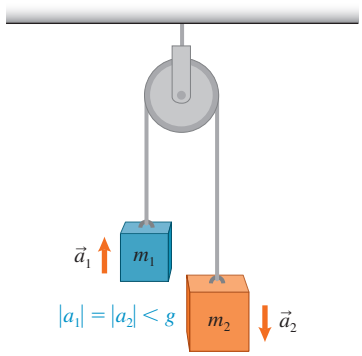
It is independent of the person's mass.

$$a_x = \frac{mg\sin\theta - \mu_k mg\cos\theta}{m} = g\sin\theta - \mu_k g\cos\theta$$

Assuming that the coefficient of kinetic friction is the same for both people and that air resistance is negligible, there will be a tie again. The acceleration of each person is

---

FIGURE 4.8 Complementary angles.



The result of Example 4.6 may surprise you, but it is reasonable. The acceleration depends on both gravitational force and mass. The gravitational force that Earth exerts on the adult (only the x-component of this force determines the acceleration in this case) is four times that exerted by Earth on the child, but because the adult's mass is four times greater than the child's, the accelerations of the adult and the child are equal. This result is similar to what we learned in Chapters 1 and 2—objects of different masses have the same free-fall acceleration.

TIP Notice in the last example that the inclined surface and the x-axis were at a 30° angle relative to the horizontal. The gravitational force exerted by Earth on the system then makes a 60° angle relative to the x-axis (60° is the complement of 30°). In general, the angle θ of the inclined surface relative to the horizontal is the complement of the angle that the gravitational force makes with respect to the inclined surface (see Figure 4.8).

Two objects linked together

We can apply Newton's second law to a process in which two objects are connected by a cable or rope, such as a van pulling a rope connected to a wagon that is pulling a rope connected to a second wagon. Perhaps the first scientific quantitative application of this type involved two blocks of different mass at the ends of a string that passed over a pulley (**Figure 4.9**). George Atwood invented this apparatus (now called the Atwood machine) in 1784. At that time, there were no motion sensors or precision stopwatches—nothing that would allow the accurate measurement of the motion of a rapidly accelerating object (9.8 m/s^2 would have been considered a rapid acceleration in those days). Atwood's machine allowed the determination of g despite these difficulties. We'll consider next a modified and simplified version of the Atwood machine, a machine that can serve the same purpose.

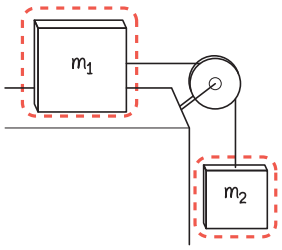


FIGURE 4.9 An Atwood machine.

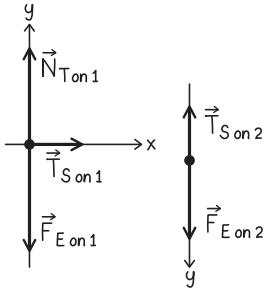
EXAMPLE 4.7 **Slowing the fall**



In a modified Atwood machine, one block rests on a smooth horizontal surface and the other hangs off the edge of the surface. A string attached to each block passes over a light, smooth pulley. Determine the force that the string exerts on the hanging block of mass m_2 and the magnitude of the acceleration of each block.

Sketch and translate We first sketch the modified Atwood machine, shown at right. For analysis we will use two systems—first block 1 and then block 2. The two blocks have masses m_1 and m_2. Block 2 starts moving down and pulls the string attached to block 1. Both blocks move with increasing speed—block 1 on the horizontal surface and block 2 downward. If the string does not stretch, then at every moment they move with the same speed. The sliding block 1 has the same magnitude acceleration as block 2, but pointing toward the right. Our goal is to find the force exerted by the string on block 2 and the magnitudes of the acceleration of the blocks.

Simplify and diagram Assume that the string is very light and does not stretch, that the pulley's mass is very small, and that the pulley is smooth and rotates free of friction. The pulley changes the direction of the low-mass string passing over it but does not change the magnitude of the force that the string exerts on the objects attached at either end. Assume also that there is no friction between the horizontal surface and block 1.

At right we show our force diagrams for each block and our choice of coordinate systems. For block 1, Earth exerts a downward gravitational force $\vec{F}_{\text{E on 1}}$; the table surface exerts an equal-magnitude upward force on block 1 $\vec{N}_{\text{T on 1}}$; and the string exerts an unknown horizontal force toward the right on the block $\vec{T}_{\text{S on 1}}$. For block 2, Earth exerts a downward gravitational force $\vec{F}_{\text{E on 2}}$ and the string exerts an unknown upward force $\vec{T}_{\text{S on 2}}$. As noted earlier, the string exerts the same magnitude force on block 1 as it does on block 2: $T_{\text{S on 1}} = T_{\text{S on 2}} = T$.

Represent mathematically Use the force diagrams to apply Newton's second law in component form for each block. For block 1, the forces in the vertical direction balance, since the vertical component of its acceleration is zero. We see by inspection of the force diagram that the gravitational force and the normal force have zero x-components and so we do not include them in the x-component equation. This leaves us with only one force in the horizontal direction—the force exerted by the string. The x-component form of Newton's second law becomes

$$m_1 a_{1x} = T_{\text{S on 1}\,x} = +T \tag{4.5}$$

For block 2, we only need to look at the vertical direction, as no forces are exerted in the horizontal direction. Notice that we've chosen the vertical y-axis pointing downward so that the y-component of block 2's acceleration will equal the x-component of block 1's acceleration. The y-component form of Newton's second law for block 2 is

$$m_2 a_{2y} = T_{\text{S on 2}\,y} + F_{\text{E on 2}\,y}$$

Noting that $T_{\text{S on 2}\,y} = -T$ and $F_{\text{E on 2}\,y} = m_2 g$, we get

$$m_2 a_{2y} = -T + m_2 g \tag{4.6}$$

Because the two blocks are connected together by the string, they move with the same speed and have accelerations of the same magnitude, block 1 to the right and block 2 down.

Solve and evaluate After substituting a for the two accelerations in Eqs. (4.5) and (4.6), the two equations now have the same two unknown quantities T and a.

$$m_1 a = T$$
$$m_2 a = -T + m_2 g$$

We substitute the expression for T from the first equation into the second to get

$$m_2 a = -m_1 a + m_2 g$$

After moving the terms containing the acceleration to the left side, factoring a out, and dividing both sides by the sum of the masses, we have

$$a = \frac{m_2 g}{m_1 + m_2}$$

(CONTINUED)

Note that the acceleration is less than g! Also note that if the mass $m_1 \gg m_2$ (m_1 much greater than m_2), then the acceleration is almost zero and can be measured easily. We can now determine the force exerted by the string on the hanging block by inserting the above expression for the acceleration into $m_1 a = T$:

$$T = m_1 a = m_1 \frac{m_2 g}{m_1 + m_2} = \frac{m_1}{m_1 + m_2} m_2 g$$

Are the results reasonable? Consider the equation for acceleration. The only force pulling the hanging block down is the gravitational force $m_2 g$ that Earth exerts on the hanging block. But because the two blocks are connected, this force has to cause the sum of their masses to accelerate [$m_2 g = (m_1 + m_2)a$], making the acceleration less than g.

Try it yourself Determine an expression for acceleration for a regular Atwood machine for which two objects of mass m_1 and m_2 move in the vertical direction ($m_1 > m_2$).

Answer

$$\frac{m_2 + m_1}{g(m_2 - m_1)} = a$$

There are two important ideas to take away from this example:

1. If we assume that the pulley is light, the magnitudes of the forces that the string on both sides of the pulley exerts on the two objects are the same.
2. If we assume that the string connecting the two objects does not stretch, the magnitudes of the accelerations of the two objects are the same.

If the above two assumptions are valid, the consequences apply to all problems involving pulleys.

We can see now how to use a modified or a regular Atwood machine to determine the acceleration g. If you measure the distance that one of the objects travels (Δy) during a particular time interval (Δt) after being released from rest, you can use the expression

$$\Delta y = \tfrac{1}{2} a (\Delta t)^2$$

to determine the acceleration of the objects. Using this value for acceleration and the values for their masses, you can use the expression

$$a = \frac{m_2 g}{m_1 + m_2}$$

for a modified machine or

$$a = \frac{(m_1 - m_2)g}{m_1 + m_2}$$

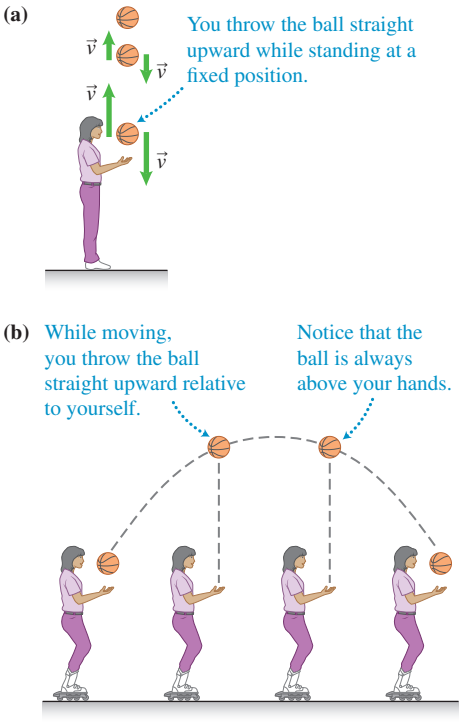
for a regular one to determine the value of g.

REVIEW QUESTION 4.4 For problems involving objects moving upward or downward along inclined surfaces, we choose the x-axis parallel to the surface and the y-axis perpendicular to the surface. Why not use horizontal and vertical axes?

4.5 Projectile motion

So far in this chapter, we have used the knowledge of Newton's laws and force components to explain the motion of objects moving along a straight line when the forces exerted on the objects have not all been in the direction of motion. Let's now look at some common objects that move along a curved path: *projectiles*. **Projectiles** are objects launched at an angle relative to a horizontal surface. We can use Newton's

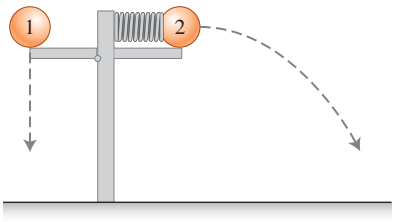
second law to analyze and explain their **projectile motion**. We will begin by constructing a qualitative explanation and then develop a quantitative description. Let's start by making some observations.



Qualitative analysis of projectile motion

You can analyze projectile motion with a basketball. First, throw the ball straight upward. It moves up and then down with respect to you and with respect to the floor and eventually returns to your hands (**Figure 4.10a**). Next, walk in a straight line at constant speed and throw the ball straight up again. Have a friend videotape you from the side. The ball goes up and returns to your hands as before, but this time you've moved along your walking path. Your friend sees a projectile—a ball traveling in an arc. Finally, put on Rollerblades and repeat the experiment several times, each time moving with greater speed. As long as you don't change your speed or direction while the ball is in flight, it lands back in your hands. The video shows that the ball moves in an arc with respect to the ground, and at every frame it is directly above your hands (Figure 4.10b). Why does this happen?

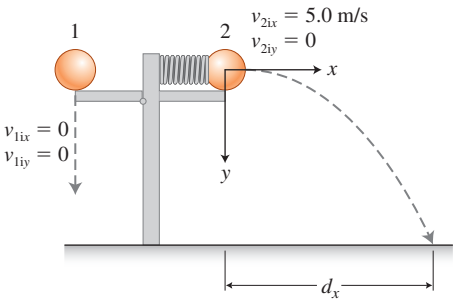
One possible explanation is that the ball moves vertically with respect to you independently of its horizontal motion with respect to the floor. Let us analyze projectile motion by considering the ball's vertical and horizontal motion independently. For you, the ball moves up and down like the ball in Figure 4.10a. An observer on the floor explains the vertical motion of the ball in the same way. Both observers are in inertial reference frames. Earth exerts a gravitational force on the ball, so its upward speed decreases until it stops at the highest point, and then its downward speed increases until it returns to your hands (the vertical component of the ball's acceleration is constant due to the gravitational force exerted on it by Earth).



In addition to this vertical motion, the ball also moves horizontally with respect to the floor, with the same constant speed as you. No object exerts a horizontal force on the ball. Thus, according to Newton's first law, the ball's horizontal velocity does not change once it is released. This velocity is the same as your velocity due to the way the ball was released. In every experiment the ball continues moving horizontally as if it were not thrown upward, and it moves up and down as if it does not move horizontally. It seems that the hypothesis that the horizontal and vertical motions of the ball are independent of each other can account for all our observations. Let's test this explanation in Testing Experiment **Table 4.6**.

FIGURE 4.10 A projectile launched by a moving person.

TESTING EXPERIMENT TABLE 4.6 Testing the independence of horizontal and vertical motions



VIDEO TET 4.6

Testing experiment	Prediction	Outcome
At time zero, ball 1 is dropped. Simultaneously, ball 2 is shot horizontally when a compressed spring is released. Which ball hits the surface first? 	Both balls start with zero initial vertical speed; thus their vertical motions are identical. Since we think that the vertical motion is independent of the horizontal motion, we predict that they will land at the same time.	When we try the experiment, the balls do land at the same time.

Conclusion

The outcome supports the hypothesis that horizontal and vertical motions are independent of each other.

FIGURE 4.11 Finding the range of a projectile thrown horizontally.

The prediction may seem counterintuitive. However, the result matched the prediction. Ball 2 travels a longer path than ball 1, so why doesn't it land later? The vertical motions of both projectiles are identical; thus they land at the same time. The second ball moves forward at constant velocity while it is falling, but this horizontal motion does not affect its vertical fall.

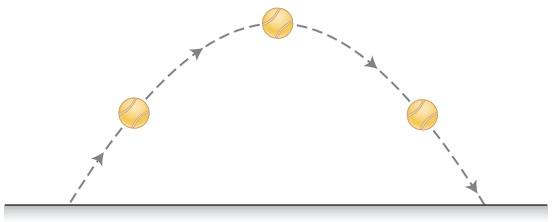
Let us now analyze the experiment in Table 4.6 quantitatively. Ball 1 is dropped from a height of 1.0 m and ball 2 is simultaneously shot horizontally from the same height at a speed of 5.0 m/s (see **Figure 4.11**). We point the vertical axis down and the horizontal axis to the right. The origin for both axes is where the balls are released. Ball 1 falls at constant acceleration because the only object exerting a force on it is Earth; its equation of motion is $y_{1f} = y_{1i} + v_{1iy}t + \frac{1}{2}a_y t_1^2 = \frac{1}{2}g t_1^2$, where we used $y_{1i} = 0$; $v_{1iy} = 0$. The *time of flight* is therefore

$$t_1 = \sqrt{\frac{2y_{1f}}{g}} = \sqrt{\frac{2.0\text{ m}}{9.8\text{ m/s}^2}} \approx 0.5\text{ s}$$

Ball 2 is also falling; its time of flight is the same as that for ball 1, $t_2 = t_1 = 0.5$ s. However, while falling, ball 2 is also moving horizontally. The displacement of the ball is $d_{2x} = v_{2ix}t_2 = (5.0\text{ m/s})(0.5\text{ s}) = 2.5$ m. This is a reasonable number because the ball does not land too far from the table. Notice that the time in which ball 2 moves horizontally is the same as the time in which it falls vertically. We can now write the expression for the horizontal distance that the ball travels during the flight as

$$d_{2x} = v_{2ix}\sqrt{\frac{2y_{1f}}{g}} \quad \text{where } y_{1f} = y_{2f}$$

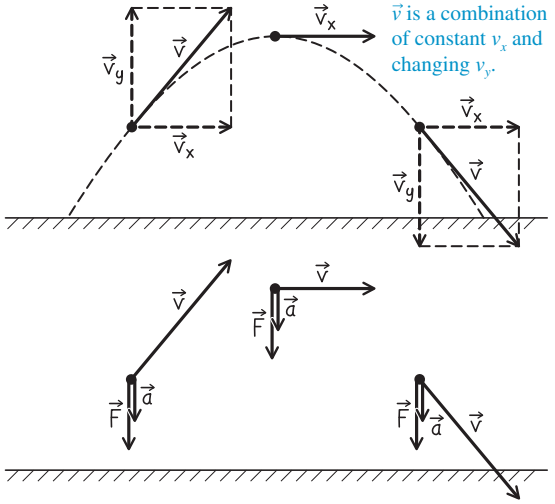
This expression is true for a horizontal throw of any projectile from height y:



$$d_x = v_{ix}\sqrt{\frac{2y}{g}}$$

Distance d is called the *range*.

We now understand both conceptually and quantitatively the motion of a ball thrown horizontally. Let us next analyze the motion of the ball thrown at an angle to the horizontal in Conceptual Exercise 4.8.



CONCEPTUAL EXERCISE 4.8 Throwing a ball

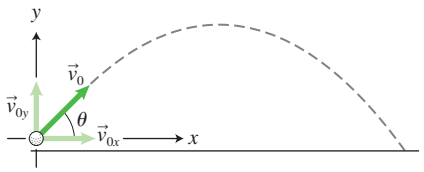
You throw a tennis ball as a projectile. Draw an arrow or arrows representing its instantaneous velocity and acceleration and the force or forces exerted on the ball by other objects when at the three positions shown below.

Sketch and translate The ball is the system of interest.

Simplify and diagram To draw velocity arrows, we consider the velocity at each point as consisting of a constant horizontal vector component and a vertical vector component whose magnitude decreases as the ball moves up and increases as it moves down. The vertical component is zero at the highest point in the trajectory. If we do this very carefully, we find that the velocity arrows are tangent to the ball's path at each position. If we ignore air resistance, only one object exerts a force on the ball—Earth. Thus in our sketch, the force arrows point down at all three positions as shown below.

The acceleration arrows point in the same direction as the sum of the forces—downward. Notice that at the top of the path, the velocity of the object is horizontal; however, the acceleration still points downward. The direction of velocity at each point and the direction of the sum of the forces exerted on the object at each point do not have to be the same.

Try it yourself How do the magnitude of the net force and the acceleration at the first position shown in the diagram compare to the magnitude of the net force and acceleration at the third position?



Answer The magnitude of the net force is the same at both positions. The magnitude of the acceleration is the same at both positions.

Quantitative analysis of projectile motion

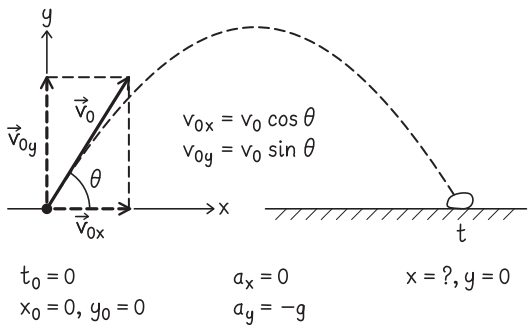
In Table 4.6, we launched a projectile horizontally. Now we will develop the mathematical description for the motion of a projectile launched at an arbitrary angle. To start, we need to choose the direction of our coordinate axes. Here, we show the analysis for the x-axis pointed to the right and the y-axis pointed up. However, we could have chosen the downward direction as positive for the y-axis. For every case, you need to decide how to point the axes for greatest convenience.

The x-component of a projectile's acceleration in the horizontal direction is zero ($a_x = 0$). The y-component of the projectile's acceleration in the vertical direction is $a_y = -g$ (choosing the y-axis to point up). Consider the projectile shown in **Figure 4.12**. When the projectile is launched at speed v_0 at an angle θ relative to the horizontal, its initial x- and y-velocity components are $v_{0x} = v_0 \cos\theta$ and $v_{0y} = v_0 \sin\theta$. The x-component of velocity remains constant during the flight, and the y-component changes in the same way that the velocity of an object thrown straight upward changes. If the motions in the x- and y-directions are independent of each other, then the equations that describe the motion of a projectile become the following:

FIGURE 4.12 The initial velocity component vectors and their magnitudes.

$v_{0x} = v_0 \cos\theta$
$v_{0y} = v_0 \sin\theta$

Projectile motion in the x-direction		Projectile motion in the y-direction	
$(a_x = 0)$		$(a_y = -g)$	
$v_x = v_{0x} = v_0 \cos\theta$	(4.7x)	$v_y = v_{0y} + a_y t = v_0 \sin\theta + (-g)t$	(4.7y)
$x = x_0 + v_{0x}t$		$y = y_0 + v_{0y}\,t + \frac{1}{2}a_y\,t^2$	
$= x_0 + (v_0 \cos\theta)t$	(4.8x)	$= y_0 + (v_0 \sin\theta)t - \frac{1}{2}gt^2$	(4.8y)



TIP Equations 4.7 and 4.8 include velocity components, whose signs depends on your choice of x- and y-axis directions. Be sure to check the signs carefully.

Equation (4.8y) can be used to determine the time interval for the projectile's flight, and Eq. (4.8x) can be used to determine how far the projectile travels in the horizontal direction during that time interval. If the projectile leaves ground level and returns to ground level (for example, when you hit a golf ball), then Eq. (4.8y) with $y_0 = 0$ and $y = 0$ can be solved for t, the time when the ball lands (assuming the ball is hit at time zero). Then Eq. (4.8x) can be used to determine the distance the projectile travels during that time interval.

EXAMPLE 4.9 Best angle for longest distance

You want to throw a rock the longest possible horizontal distance. You keep the initial speed of the rock constant and find that the horizontal distance it travels depends on the angle at which it leaves your hand. What is the angle at which you should throw the rock so that it travels the longest horizontal distance, assuming you throw it with the same initial speed?

Sketch and translate We sketch the rock's trajectory, including a coordinate system and the initial velocity of the rock when it leaves your hand. The origin is at the position of the rock at the moment it leaves your hand. We call that initial time $t_0 = 0$.

(CONTINUED)

Simplify and diagram Assume that the rock leaves at the same elevation as it lands. That's not actually what happens, since the rock leaves your hand several feet above the ground, but it is a reasonable assumption if the rock travels a long distance compared to its initial height above the ground. Assume also that the rock is a point-like object and that the drag force exerted by the air on the rock does not affect its motion.

Represent mathematically First, determine the time interval that the rock is in flight using Eq. (4.8y). Note that because of the coordinate system we chose, $y_0 = y = 0$ and $t_0 = 0$:

$$0 = 0 + (v_0 \sin\theta)t - \tfrac{1}{2}gt^2$$

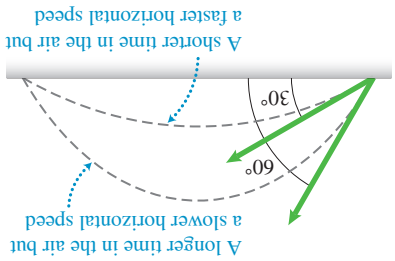
Dividing both sides of the equation by t and then solving for t, we obtain

$$t = \frac{2v_0 \sin\theta}{g}$$

This is the time of flight—we see that it depends only on the initial velocity of the rock and the launch angle. To determine the distance that the rock travels in the horizontal direction, insert this expression for t into Eq. (4.8x), and note that $x_0 = 0$:

$$x = (v_0 \cos\theta)t = v_0 \cos\theta\left(\frac{2v_0 \sin\theta}{g}\right) = \frac{v_0^2\, 2 \sin\theta \cos\theta}{g}$$

Solve and evaluate Recall from trigonometry that $2 \sin\theta \cos\theta = \sin(2\theta)$. This lets us rewrite the above equation as



$$x = \frac{v_0^2 \sin 2\theta}{g}$$

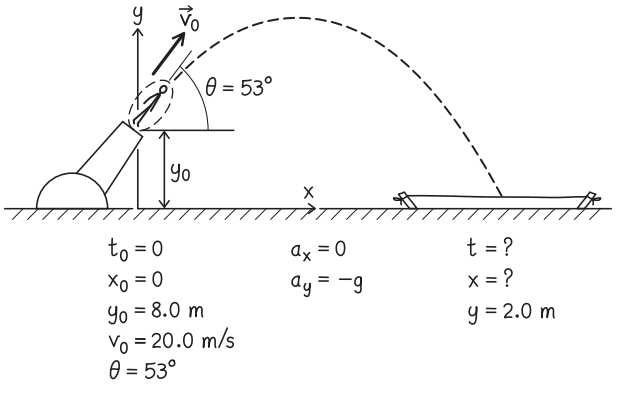
Our goal is to determine what launch angle will result in the rock traveling the farthest. Remember that the sine of an angle has a maximum value of 1 when the angle is 90°. Thus, $\sin 2\theta = 1$ when $2\theta = 90°$ or when $\theta = 45°$. The rock will travel the maximum horizontal distance when you launch it at an angle of 45° above the horizontal.

This answer seems reasonable. If you throw the rock at a smaller angle, the vertical component of the velocity is small and it spends less time in flight. If you launch it at an angle closer to 90°, it spends more time in flight, but its horizontal velocity component is small, so it does not travel very far horizontally. The 45° angle is a compromise between long time of flight and large horizontal velocity.

Try it yourself Will the rock travel farther if it is launched at a 60° angle or at a 30° angle?

Answer

It will travel the same distance in each case (see below).



Human cannonballs

Calculating projectile motion is not always as simple as Eqs. (4.7) and (4.8) suggest. Human cannonball launches must use complicated formulas to account for the effect of air resistance. Results obtained from Eqs. (4.7) and (4.8) are correct only in the absence of air resistance or if air resistance is small. Even so, we will use the simplified equations in the next example.

EXAMPLE 4.10 **Shot from a cannon**

Stephanie Smith Havens (sister of David Smith, Jr.) is shot from a cannon at speed 20 m/s. The end of the cannon's barrel is 8.0 m above the ground, and the barrel is oriented at 53° above the horizontal. Stephanie enjoys her flight until she touches the net, positioned 2.0 m above ground level. The net stretches to reduce the force exerted on her while stopping her. (1) Determine the time Stephanie spends in flight. (2) Determine the horizontal distance from the end of the barrel where the net should be placed so that she lands safely.

Sketch and translate We make a sketch of Stephanie's flight, including a coordinate system, the known information, and the desired unknowns. We call the clock reading when she leaves the barrel $t_0 = 0$. The origin of the coordinate system is at ground level directly below the end of the barrel.

Simplify and diagram We assume that Stephanie can be treated as a point-like object and that air resistance can be ignored. (This is a reasonable assumption if her flight is not too long, but it might not be appropriate for the proposed flight. We will, however, ignore air resistance, as we do not yet have the tools to deal with it.) A force diagram for Stephanie as a system is shown at right.

Represent mathematically (1) First determine the time that Stephanie is in flight using Eq. (4.8*y*):

$$y - y_0 = v_0 \sin 53° t + \tfrac{1}{2}(-9.8\text{ m/s}^2)t^2$$

where $y = 2.0$ m, $y_0 = 8.0$ m, $v_0 = 20$ m/s, and $\sin 53° = 0.80$. (2) To determine the horizontal distance $x - x_0$ Stephanie travels to reach the net, use the time results from Part 1 and Eq. (4.8*x*):

$$x - x_0 = (20\text{ m/s})\cos 53° t \quad \text{where } \cos 53° = 0.60$$

Solve and evaluate (1) We solve the following quadratic equation to find the flight time:

$$2.0\text{ m} - 8.0\text{ m} = (20\text{ m/s})\sin 53° t + \tfrac{1}{2}(-9.8\text{ m/s}^2)t^2$$

or

$$0 = (-4.9\text{ m/s}^2)t^2 + (16\text{ m/s})t + 6.0\text{ m}$$

The above is a quadratic equation, $t_{1,2} = \dfrac{-b \pm \sqrt{b^2 - 4ac}}{2a}$, where $a = -4.9$ m/s^2, $b = 16$ m/s, and $c = 6.0$ m. The solutions are

$$t_{1,2} = \frac{-(16\text{ m/s}) \pm \sqrt{(16\text{ m/s})^2 - 4(-4.9\text{ m/s}^2)(6.0\text{ m})}}{2(-4.9\text{ m/s}^2)}$$

$$\Rightarrow t_1 = -0.340\text{ s}, t_2 = 3.61\text{ s}$$

The negative solution is a hypothetical time before the actual process started. The time when she actually reaches the net is 3.61 s.

(2) The horizontal distance Stephanie travels during the 3.61 s is

$$x - x_0 = (20\text{ m/s})(\cos 53°)t = 43\text{ m}$$

This is a reasonable number and has the correct units. However, remember that we ignored the effects of air resistance in calculating this distance. In real life, air resistance needs to be taken into account.

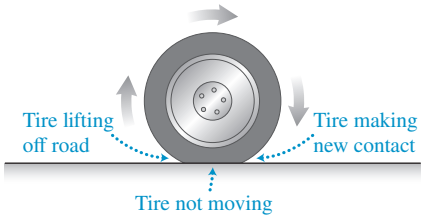
Try it yourself Suppose that the following equations describe Stephanie's next cannonball performance, which has different orientation of the cannon, location of the end of the cannon barrel, and location of the net. Solve the equations for the unknowns and invent a problem that is consistent with the equations.

$$0 = 19.6\text{ m} + 0 + \tfrac{1}{2}(-9.8\text{ m/s}^2)t^2; \quad 40\text{ m} - 0 = (v_0 \cos 0°)t$$

Answer Stephanie is shot horizontally from a horizontally oriented cannon barrel that is 19.6 m above the net. She leaves the barrel at speed 20 m/s. It takes 2.0 s for her to fall the 19.6 m to the level of the net.

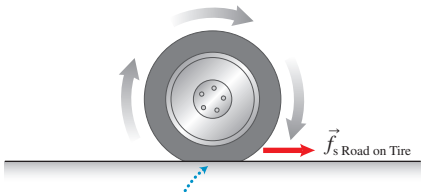
REVIEW QUESTION 4.5 Why do we need to resolve the initial velocity of a projectile into components when we analyze situations involving projectiles?

4.6 Starting and stopping a car



Each second of our lives is affected by phenomena that can be described and explained using Newton's laws—the cycles of day and night, the four seasonal variations, walking, driving cars, riding bicycles, and throwing and catching balls. We have already explored walking as a function of Newton's laws. In this section, we will analyze another everyday phenomenon, starting and stopping a car.

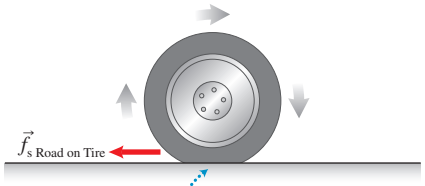
When a car is moving, the wheels turn relative to the road surface. The part of the tire immediately behind the part in contact with the surface is lifting up off the road, and the part of the tire immediately in front of the part in contact is moving down to make new contact with the road. But the part of the tire in contact with the road is at rest with respect to the road—for just a short time interval (**Figure 4.13a**)—just as your foot is stationary relative to the ground as your body moves forward while walking or running.



Increasing or decreasing the car's speed involves static friction between the tire's region of contact and the pavement. How can this be? If you want to move faster, the tire turns faster and pushes back harder on the pavement (Figure 4.13b). The pavement in turn pulls forward more on the tire (Newton's third law) and helps accelerate the car forward. If you want to slow down, the tire turns slower and pulls forward on the pavement (Figure 4.13c). The pavement in turn pushes back on the tire (Newton's third law) and helps the car accelerate backwards. Thus, the static friction force exerted by the road on the car can cause the car to speed up or slow down depending on the direction of that force.

FIGURE 4.13 Static friction helps a car accelerate.

(a) Tire is moving to the right at constant speed.



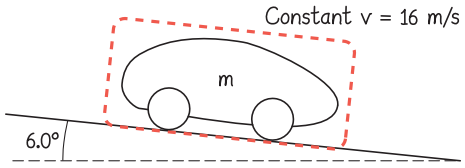
(b) Tire is moving to the right and turning faster.

If the tire turns faster, it pushes back harder on the road. The road in turn pushes forward on the tire, causing the car to accelerate to the right.

(c) Tire is moving to the right and turning slower.

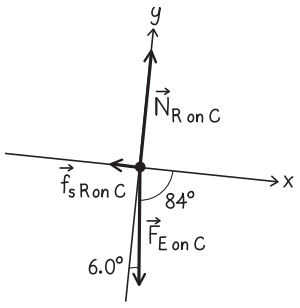
If the tire turns slower, it pulls forward on the road and the road pushes back on the tire, exerting a force that slows the car, causing it to accelerate backward.

Because the coefficient of static friction between the tire and the road is greater than the coefficient of kinetic friction, stopping is more efficient if your tires do not skid but instead roll to a stop. This is why vehicles are equipped with antilock brakes: to keep the tires rolling on the road instead of locking up and skidding.



Static friction not only helps a car speed up and slow down but also plays an important role in maintaining a car's constant speed. Without this additional force, the car would eventually slow down, because oppositely directed forces, such as air resistance and rolling resistance, point opposite the car's forward motion. A car's engine makes the axle and car tires rotate. The tires push back on the road and the road in turn pushes forward on the car in the opposite direction. The forward static friction force that the road exerts on the car keeps the car moving at constant speed. The presence of air resistance and rolling resistance explains why when you are driving you must continually give the engine gas; otherwise, you would not be able to maintain constant speed and your car would slow down.

TIP Some people think that the car's engine exerts a force on the car that starts the car's motion and helps it maintain its constant speed despite the air resistance. However, the forces that the engine exerts on other parts of the car are internal forces. Only external forces exerted by objects in the environment can affect the car's acceleration. The engine does rotate the wheels, and the wheels push forward or back on the ground. However, it is the ground (an external object) that pushes backward or forward on the wheels causing the car to slow down or speed up. The force that is responsible for this backward or forward push is the static friction force that the road exerts on the car tires.

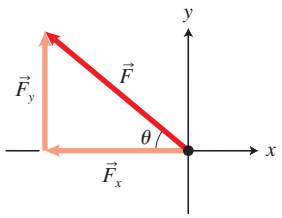


CONCEPTUAL EXERCISE 4.11 Car going down a hill

Your car moves down a 6.0° incline at a constant speed of 16 m/s, and is not skidding. Describe everything you can about the friction force that the road exerts on your car.

Sketch and translate Sketch the situation as shown. Since the car is moving at constant velocity, the sum of the forces that other objects exert on the car must be zero. We use this information to help construct a force diagram for the car and then determine the direction and relative magnitude of the friction force that the road exerts on the car.

Simplify and diagram Model the car as a point-like object and assume that air resistance does not significantly affect the motion of the car. Make a force diagram for the car. The *x*-axis points in the direction of motion, and the *y*-axis points perpendicular to the road surface. Earth exerts a downward force on the car, and the surface exerts a force that we resolve into two vector components: the component perpendicular to the surface (the normal force) and the component parallel to the surface (the static friction force). This static friction force points in the direction opposite to the car's motion, similarly to the situation in Figure 4.13c. To achieve such a direction of the static friction force, the driver must use the brakes to slow down the rotation of the wheels. According to the force diagram, the angle between the arrow for the gravitational force and the *y*-axis is 6°. If we had included air resistance, the static friction force would not have had to be as large in order to balance the *x*-component of the gravitational force.

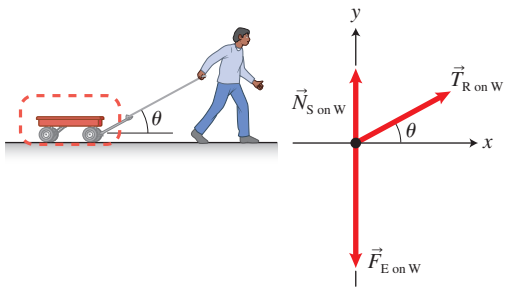


Try it yourself A car moves at a high, constant velocity on a horizontal, level road. Does the road exert a static friction force on the car, and if so, in what direction?

Answer Air resistance becomes more important at high speeds and can exert a several hundred newton force on the car that opposes its motion. Thus, the road now has to exert a static friction force on the car tires that pushes the car in the forward direction—the tires push back on the road, and the road in turn pushes forward on the tires.

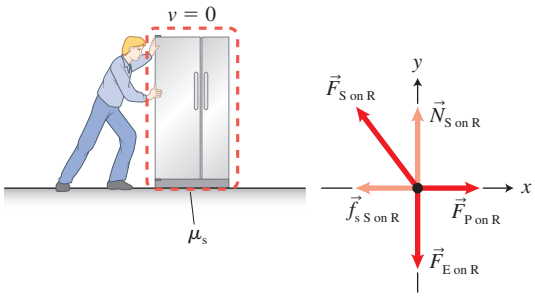
REVIEW QUESTION 4.6 You read in this section that it is the road and not the engine that is most directly responsible for a car speeding up. Why is this true?

Summary



Components of a vector quantity A vector quantity such as force $\vec{F}$ can be broken into its scalar components F_x and F_y, which indicate the effect of the force in two perpendicular directions. (Section 4.1)

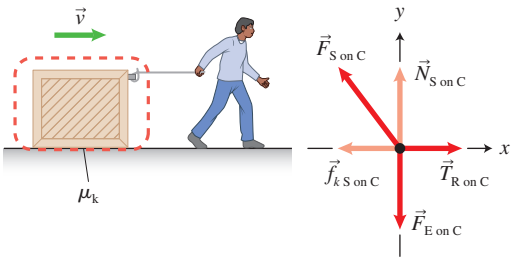
$$F_x = \pm F\cos\theta \qquad \text{Eq. (4.1}x\text{)}$$
$$F_y = \pm F\sin\theta \qquad \text{Eq. (4.1}y\text{)}$$



θ is the angle relative to the $\pm x$-axis. A scalar component is positive if it falls along a positive axis and negative if it falls along a negative axis.

Newton's second law in component form The acceleration of an object in the x-direction is the sum of the x-components of the forces exerted on it divided by its mass. The acceleration of the object in the y-direction is the sum of the y-components of the forces divided by its mass. (Section 4.2)

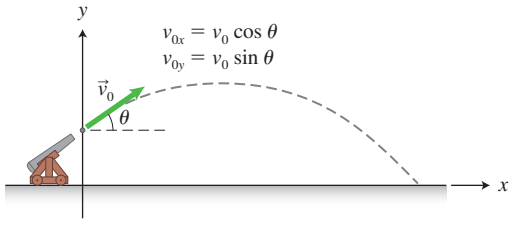
$$a_{\text{S}x} = \frac{F_{1\text{ on S}\,x} + F_{2\text{ on S}\,x} + F_{3\text{ on S}\,x} + \cdots}{m_{\text{S}}} \qquad \text{Eq. (4.2}x\text{)}$$
$$a_{\text{S}y} = \frac{F_{1\text{ on S}\,y} + F_{2\text{ on S}\,y} + F_{3\text{ on S}\,y} + \cdots}{m_{\text{S}}} \qquad \text{Eq. (4.2}y\text{)}$$



Static friction force When two objects are in contact and we try to move one across the other, they exert forces on each other. Components of these forces parallel to the surfaces are static friction forces; they oppose the tendency of the objects to move with respect to each other. Static friction forces are exerted on both interacting objects, but we are usually concerned with one of the objects, which we call the system. This static friction force changes magnitude as needed to prevent motion of the system, up to a certain maximum value. (Section 4.3)

The maximum static friction force depends on the roughness of the two surfaces (on the coefficient of static friction μ_s between the surfaces), and it is related to the magnitude of the normal force $N_{\text{S on O}}$ component exerted by one surface on the other. The magnitude of the static friction force is always less than or equal to the product of these two quantities:

$$0 \le f_{s\,\text{S on O}} \le \mu_s N_{\text{S on O}} \qquad \text{Eq. (4.3)}$$



Kinetic friction force When an object slides along a surface, the parallel to the surface components of the forces that the object and surface exert on each other are called kinetic friction forces. (Section 4.3)

The kinetic friction force depends on the surfaces themselves (on the coefficient of kinetic friction μ_k) and is related to the magnitude of the normal force $N_{\text{S on O}}$ component exerted by one surface on the other.

$$f_{k\,\text{S on O}} = \mu_k N_{\text{S on O}} \qquad \text{Eq. (4.4)}$$

Projectile motion Projectiles are objects launched either horizontally or at an angle with the horizontal. Horizontal and vertical motions of projectiles are independent of each other. If we ignore the resistive force that air exerts on the projectile, then its horizontal acceleration is zero ($a_x = 0$) and its vertical acceleration is the free-fall acceleration ($a_y = -g$). (Section 4.5)

x-direction equations:

$$x = x_0 + v_{0x}t \qquad \text{Eq. (4.8}x\text{)}$$
$$v_x = v_0\cos\theta = \text{constant} \qquad \text{Eq. (4.7}x\text{)}$$

y-direction equations (if positive direction up):

$$y = y_0 + v_{0y}t + \tfrac{1}{2}a_y t^2 \qquad \text{Eq. (4.8}y\text{)}$$
$$v_y = v_0\sin\theta + (-g)t \qquad \text{Eq. (4.7}y\text{)}$$

Questions

Multiple Choice Questions

1. A car accelerates along a road. Identify the best combination of forces exerted on the car in the horizontal direction that explains the acceleration.
   (a) The force exerted by the engine in the direction of motion and the kinetic friction force exerted by the road in the opposite direction
   (b) The static friction force exerted by the road in the direction of motion and the kinetic friction force exerted by the road in the opposite direction
   (c) The static friction force exerted by the road in the direction of motion and the friction force exerted by the air in the opposite direction
2. A person pushes a 10-kg crate exerting a 200-N force on it, but the crate's acceleration is only 5 m/s^2. Explain.
   (a) The crate pushes back on the person.
   (b) Not enough information is given.
   (c) There are other forces exerted on the crate.
3. Compare the ease of pulling a lawn mower and pushing it.
   (a) They are the same. (b) Pulling is easier.
   (c) Pushing is easier. (d) Not enough information is given.
4. You simultaneously release two balls: one you throw horizontally, and the other you drop straight down. Which one will reach the ground first? Why?
   (a) The ball dropped straight down lands first, since it travels a shorter distance.
   (b) Neither. Their vertical motion is the same, so they will reach the ground at the same time.
   (c) It depends on the mass of the balls—the heavier ball falls faster so lands first.
5. You shoot an arrow with a bow. The following is Newton's second law applied for one of the instants in the arrow's trip: $m\vec{a} = m\vec{g}$. Choose the instant that best matches the equation description.
   (a) The arrow is accelerating while contacting the bowstring.
   (b) The arrow is flying up.
   (c) The arrow is slowing down while sinking into the target.
   (d) This equation does not describe any part of the arrow's trip.
6. In what reference frame does a projectile launched at speed v_0 at angle θ above the horizontal move only in the vertical direction?
   (a) There is no such reference frame.
   (b) In a reference frame that moves with the projectile
   (c) In a reference frame that moves horizontally at speed $v_0 \cos\theta$
   (d) In a reference frame that moves horizontally at speed v_0
7. In Table 4.6 we found that the two balls touched the ground at the same time. Which of the following quantities is/are also equal for both balls after they have been launched? Multiple answers could be correct.
   (a) Acceleration in the y-direction (b) Acceleration in the x-direction
   (c) Speed at landing (d) Average speed
8. While running at constant velocity, how should you throw a ball with respect to you so that you can catch it yourself, without needing to reach for the ball?
   (a) Slightly forward (b) Slightly backward
   (c) Straight up (d) It is impossible.
9. You hold a block on a horizontal, frictionless surface. It is connected by a string that passes over a pulley to a vertically hanging block (a modified Atwood machine). What is the magnitude of the acceleration of the hanging object after you release the block on the horizontal surface?
   (a) Less than g (b) More than g (c) Equal to g
   (d) Any of the answers a–c, depending on the masses of the blocks.
10. In the process described in the previous question, what is the magnitude of the force exerted by the string on the block on the horizontal plane after it is released?
    (a) Equal to the force that Earth exerts on the hanging block
    (b) Less than the force exerted by Earth on the hanging block
    (c) More than the force exerted by Earth on the hanging block
11. Suppose that two blocks are positioned on an Atwood machine so that the block on the right of mass m_1 hangs at a lower elevation than the block on the left of mass m_2. Both blocks are at rest. Based on this observation, what can you conclude?
    (a) $m_1 > m_2$ (b) $m_1 = m_2$ (c) $m_1 < m_2$
    (d) You cannot conclude anything with the given information.
12. A box containing some stones is resting on a rough inclined surface. Which of the following actions will definitely *not* make the box start moving down the incline? Multiple answers could be correct.
    (a) Push the box in the direction that is down the incline.
    (b) Remove the box, polish the inclined surface with sandpaper, and put the box back.
    (c) Increase the angle of the incline.
    (d) Take some stones out of the box.
    (e) Put more stones into the box.
13. For the following two questions, the answer options are the same. Select two correct answers for each question from the list below.
    I. A box containing some stones is resting on a rough inclined surface. What do you need to do to increase the force of static friction exerted on the box?
    II. A box containing some stones is moving with constant acceleration down a rough inclined surface. What do you need to do to increase the force of kinetic friction exerted on the box?
    (a) Increase the angle of the incline.
    (b) Decrease the angle of the incline.
    (c) Put more stones into the box.
    (d) Take some stones out of the box.
14. A block is resting on a rough inclined surface. You observe that by increasing the angle of the incline, you can make the block start moving down the incline. Which answer best explains why the block starts moving?
    (a) By increasing the angle of the incline, you increase the component of the force exerted by Earth on the block, which pulls the block down the incline.
    (b) By increasing the angle of the incline, you decrease the maximum static friction force exerted on the block by the surface.
    (c) By increasing the angle of the incline, you simultaneously increase the component of the force exerted by Earth on the block and decrease the maximum static friction force exerted on the block.

Conceptual Questions

15. A box with a heavy television set in it is placed against a box with a toaster oven in it. Both sit on the floor. Draw force diagrams for the TV box and the toaster oven box if you push the TV box to the right, exerting a force $\vec{F}_{\text{Y on TV}}$. Repeat for the situation in which you are exerting a force of exactly the same magnitude and direction, but pushing the toaster oven box, which in turn pushes the TV box.
16. How can an Atwood machine be used to determine the acceleration of freely falling objects if none of the objects used is in the state of free fall?
17. Your friend is on Rollerblades holding a pendulum. You gently push her forward and let go. You observe that the pendulum first swings in the opposite direction (backward) and then returns to the vertical orientation as she coasts forward. (a) Draw a force diagram to explain the behavior of the pendulum bob as your friend is being pushed. (b) How can you use it to determine the acceleration of your friend while you are pushing her? (c) Why does the pendulum return to its vertical orientation after you stop pushing your friend?
18. Explain why a car starts skidding when a driver abruptly applies the brakes.
19. Explain why old tires need to be replaced.
20. Explain how friction helps you to walk.
21. Explain why you might fall forward when you stumble.
22. Explain why you might fall backward when you slip.
23. Explain why the tires of your car can "spin out" when you are caught in the mud.
24. You throw two identical balls simultaneously at the same initial speed, one downward and the other horizontally. Describe and compare their motions in as much detail as you can.
25. Your friend says that the vertical force exerted on a projectile when at the top of its flight is zero. Why would he say this? Do you agree or disagree? If you disagree, how would you convince your friend that your opinion is correct?
26. Your friend says that a projectile launched at an angle relative to the horizontal moves forward because it retains the force of the launcher. Why would she say this? Do you agree or disagree? If you disagree, how would you convince your friend that your opinion is correct?

27. An object of mass m_1 placed on an inclined plane (angle θ relative to the horizontal) is connected by a string that passes over a pulley to a hanging object of mass m_2 ($m_2 \gg m_1$). Draw a force diagram for each object. Do not ignore friction.
28. An object of mass m_1 placed on an inclined plane (angle θ relative to the horizontal) is connected by a string that passes over a pulley to a hanging object of mass m_2 ($m_1 \gg m_2$). Draw a force diagram for each object. Do not assume that friction can be ignored.
29. A horse is pulling a sled. If the force exerted by the horse on the sled has the same magnitude as but the opposite direction to the force exerted by the sled on the horse, how are the horse and the sled able to start moving forward? Choose all the explanations that you consider to be correct.
    (a) If the system is the horse and the sled, then to explain the system's motion we need to consider the external forces exerted on it. The sum of these forces causes the forward acceleration of the system.
    (b) If we consider the horse to be the system, and if the sum of the friction force and the force exerted by the sled points in the forward direction, the horse will accelerate in the same direction.
    (c) For a brief instant right before the sled starts moving, the horse pulls slightly harder on the sled than the sled pulls back on it. This slight imbalance allows them both to start moving.
30. If you kick a block so that it starts moving up a rough incline, you observe that the acceleration of the block while moving up the incline is different from the acceleration when the block is sliding back down the incline. (a) Draw a force diagram for the block when it is moving up the incline and down the incline. (b) Explain why the accelerations are different and compare their magnitudes.

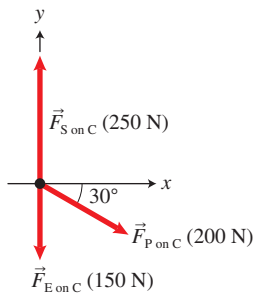
Problems

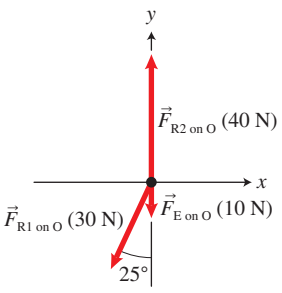
Below, BIO indicates a problem with a biological or medical focus. Problems labeled EST ask you to estimate the answer to a quantitative problem rather than derive a specific answer. Asterisks indicate the level of difficulty of the problem. Problems with no * are considered to be the least difficult. A single * marks moderately difficult problems. Two ** indicate more difficult problems.

4.1 Vectors in two dimensions and force components

1. Determine the x- and y-components of each force vector shown in **Figure P4.1**.

FIGURE P4.1





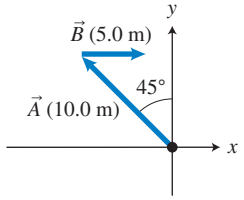


FIGURE P4.2

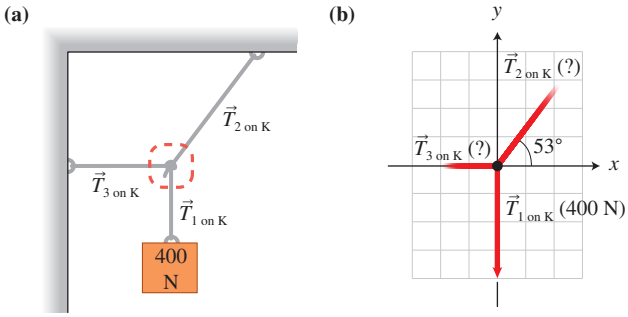
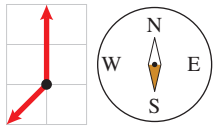
2. Determine the x- and y-components of each force vector shown in **Figure P4.2**.
3. * Determine the x- and y-components of each displacement shown in **Figure P4.3**.
4. * The x- and y-components of several unknown forces are listed below (F_x, F_y). For each force, draw on an x, y coordinate system the components of the force vectors. Determine the magnitude and direction of each force: (a) (+100 N, −100 N), (b) (−300 N, −400 N), and (c) (−400 N, +300 N).

FIGURE P4.3



5. * The x- and y-scalar components of several unknown forces are listed below (F_x, F_y). For each force, draw an x, y coordinate system and the vector components of the force vectors. Determine the magnitude and direction of each force: (a) (−200 N, +100 N), (b) (+300 N, +400 N), and (c) (+400 N, −300 N).

4.2 and 4.3 Newton's second law in component form and Friction



6. * Three ropes pull on a knot shown in **Figure P4.6a**. The knot is not accelerating. A partially completed force diagram for the knot is shown in Figure P4.6b. Use qualitative reasoning to determine the magnitudes of the forces that ropes 2 and 3 exert on the knot. Explain in words how you arrived at your answer.

FIGURE P4.6

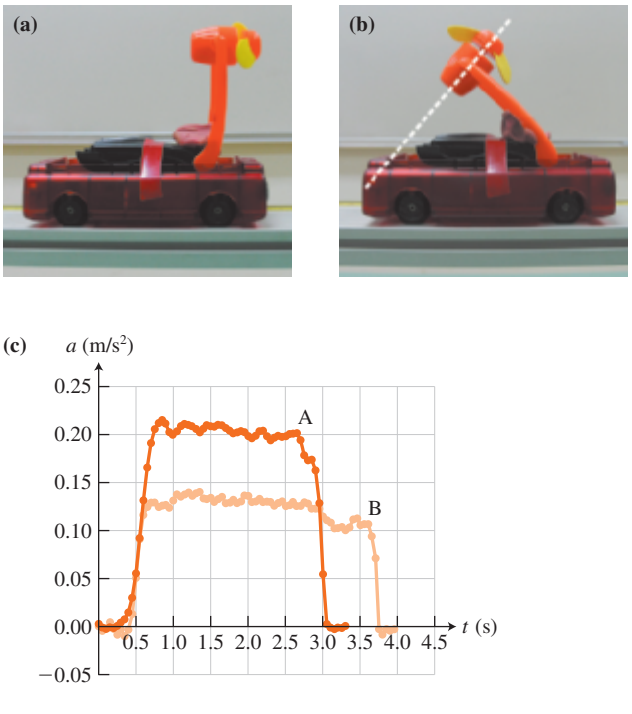
7. * **Figure P4.7** shows an unlabeled force diagram for a hockey puck. The length of the sides of the square grid corresponds to a force magnitude of 1 N. Draw a similar square grid on paper and then draw the vector for the force that should be exerted on the puck so that the puck (a) moves with constant speed, (b) moves with constant acceleration toward the north, (c) moves with constant acceleration toward the west, and (d) moves with constant acceleration toward the east.

FIGURE P4.7

8. For each of the following situations, draw the forces exerted on the moving object and identify the other object causing each force. (a) You pull a wagon along a level floor using a rope oriented 45° above the horizontal. (b) A bus moving on a horizontal road slows in order to stop. (c) You slide down an inclined waterslide. (d) You lift your overnight bag into the overhead compartment on an airplane. (e) A rope connects two boxes on a horizontal floor, and you pull horizontally on a second rope attached to the right side of the right box (consider each box separately).

9. * Write Newton's second law in component form for each of the situations described in Problem 4.8.
10. For the situations described here, construct a force diagram for the block, sled, and skydiver. (a) A cinder block sits on the ground. (b) A rope pulls at an angle of 30° relative to the horizontal on a sled moving on a horizontal surface. The sled moves at increasing speed toward the right (the surface is not smooth.) (c) A rope pulls on a sled parallel to an inclined slope (inclined at an arbitrary angle). The sled moves at increasing speed up the slope. (d) A skydiver falls downward at constant terminal velocity (air resistance is present).
11. * Write Newton's second law in component form for each of the situations described in Problem 4.10.
12. * Apply Newton's second law in component form for the force diagram shown in Figure P4.1.
13. * Apply Newton's second law in component form for the force diagram shown in Figure P4.2.
14. * **Equation Jeopardy 1** The three sets of equations below are the horizontal x- and vertical y-component forms of Newton's second law applied to three physical processes. For each case, solve for the unknowns. Then work backward and construct a force diagram for the object of interest and invent a problem for which the equations could be an answer (there are many possibilities). Note the difference between N (unit of force, newton) and N (the symbol for the normal force).

(a)
$$(5.0\text{ kg})a_x = (50\text{ N})\cos 30^\circ + N\cos 90^\circ + (5.0\text{ kg})(9.8\text{ N/kg})\cos 90^\circ$$
$$(5.0\text{ kg})0 = (-50\text{ N})\sin 30^\circ + N\sin 90^\circ - (5.0\text{ kg})(9.8\text{ N/kg})\sin 90^\circ$$



(b) This process involves an object on an incline.
$$(5.0\text{ kg})a_x = (30\text{ N})\cos 30^\circ + N\cos 90^\circ - (5.0\text{ kg})(9.8\text{ N/kg})\cos 60^\circ$$
$$(5.0\text{ kg})0 = (30\text{ N})\sin 30^\circ + N\sin 90^\circ - (5.0\text{ kg})(9.8\text{ N/kg})\sin 60^\circ$$

(c)
$$(5.0\text{ kg})a_x = (50\text{ N})\cos 30^\circ + N\cos 90^\circ + (5.0\text{ kg})(9.8\text{ N/kg})\cos 90^\circ$$
$$(5.0\text{ kg})0 = (-50\text{ N})\sin 30^\circ + N\sin 90^\circ - (5.0\text{ kg})(9.8\text{ N/kg})\sin 90^\circ$$
$$x - 0 = (2.0\text{ m/s})(4.0\text{ s}) + \tfrac{1}{2}a_x(4.0\text{ s})^2$$

Provide all the information you know about your process.

15. * You exert a force of 100 N on a rope that pulls a sled across a very smooth surface. The rope is oriented 37° above the horizontal. The sled and its occupant have a total mass of 40 kg. The sled starts at rest and moves 10 m. List all the quantities you can determine using these givens and determine three of the quantities on the list.
16. * You exert a force of a known magnitude F on a grocery cart of total mass m. The force you exert on the cart points at an angle θ below the horizontal. If the cart starts at rest, determine an expression for the speed of the cart after it travels a distance d. Ignore friction.
17. * **Olympic 100-m dash start** At the start of his race, 86-kg Olympic 100-m champion Usain Bolt from Jamaica pushes against the starting block, exerting an average force of 1700 N. The force that the block exerts on his foot points 20° above the horizontal. Determine his horizontal speed after the force is exerted for 0.32 s. Indicate any assumptions you made.
18. * **Your own accelerometer** A train has an acceleration of magnitude 1.4 m/s^2 while stopping. A pendulum with a 0.50-kg bob is attached to a ceiling of one of the cars. Determine everything you can about the pendulum during the deceleration of the train.
19. * EST Finn and Hazel are using a battery-powered fan fixed on a low-friction cart. As the fan blades rotate, they exert a force on the air and therefore the air exerts an equal and opposite force on the blades, causing the cart to move at constant acceleration. They decide to investigate how the acceleration of the cart depends on the tilt of the fan. They conduct two experiments: one with the fan oriented horizontally (see **Figure P4.19a**) and one by tilting the axis of the fan by a certain angle (Figure P4.19b). In both experiments, they hold the cart still, turn on the fan, then let the cart move for some time before stopping the cart. During the experiment they measure the acceleration of the cart using a motion detector. The graphs in Figure P4.19c show their measurements.
(a) Which graph (A or B) belongs to the cart with the horizontal fan and which to the cart with the tilted fan? Explain. (b) Based on the graph, estimate the angle between the axis of the fan and the horizontal in the second experiment. Indicate any assumptions that you made. Check how your result compares with the angle on the photo (Figure P4.19c) of the actual experimental setup (you will need a protractor). Indicate any assumptions that you made.

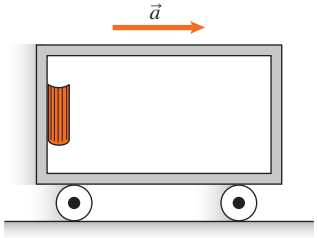


FIGURE P4.19

20. A 91.0-kg refrigerator sits on the floor. The coefficient of static friction between the refrigerator and the floor is 0.60. What is the minimum force that one needs to exert on the refrigerator to start the refrigerator sliding?
21. A 60-kg student sitting on a hardwood floor does not slide until pulled by a 240-N horizontal force. Determine the coefficient of static friction between the student and floor.
22. **Car stopping distance and friction** A car traveling at 60 mi/h (97 km/h) can stop in 48 m on a level road. Determine the coefficient of friction between the tires and the road. Assume that the car starts skidding the moment the driver hits the brakes. Is this kinetic or static friction? Explain.
23. * A 50-kg box rests on the floor. The coefficients of static and kinetic friction between the bottom of the box and the floor are 0.70 and 0.50, respectively. (a) What is the minimum force a person needs to exert on the box to start it sliding? (b) After the box starts sliding, the person continues to push it, exerting the same force. What is the acceleration of the box?
24. * Marsha is pushing down and to the right on a 12-kg box at an angle of 30° below horizontal. The box slides at constant velocity across a carpet whose coefficient of kinetic friction with the box is 0.70. Determine three physical quantities using this information, one of which is a kinematics quantity.

25. * You want to determine the coefficient of kinetic friction between a 1 m × 1 m rug and a wooden floor. You obtain a piece of the same rug of size 10 cm × 10 cm (which has a surface area 100 times smaller than the entire rug), a scale for measuring mass, a force meter, and an object of mass m_O. Which of the following procedures would you choose to obtain the correct value of kinetic friction between the rug and the floor?
    (a) Put the object on the piece of rug. Measure the force $F_{H\text{ on RP}}$ exerted by the hand on the rug piece in the horizontal direction while moving it with constant speed along the wooden floor. Calculate the coefficient of kinetic friction as $\mu_k = \dfrac{F_{H\text{ on RP}}}{m_O g}$.
    (b) Use the same method described in (a) but calculate the coefficient of friction as $\mu_k = \dfrac{100 \cdot F_{H\text{ on RP}}}{m_O g}$.
    (c) Use the same method described in (a) but also measure the mass of the rug piece m_{RP} and calculate the coefficient of friction as $\mu_k = \dfrac{F_{H\text{ on RP}}}{(m_O + m_{RP})g}$.
    (d) Use the same method described in (c) but calculate the coefficient of friction as $\mu_k = \dfrac{100 \cdot F_{H\text{ on RP}}}{(m_O + m_{RP})g}$.
26. * A wagon is accelerating to the right. A book is placed against the interior back wall of the wagon and does not slide down (see Figure P4.26). Explain how this can be.

FIGURE P4.26

27. ** In Problem 4.26, the coefficient of static friction between the book and the vertical back of the wagon is μ_s. Determine an expression for the minimum acceleration of the wagon in terms of μ_s so that the book does not slide down. Does the mass of the book matter? Explain.
28. * A car has a mass of 1520 kg. While traveling at 20 m/s, the driver applies the brakes to stop the car on a wet surface with a 0.40 coefficient of friction. (a) How far does the car travel before stopping? (b) If a different car with a mass 1.5 times greater is on the road traveling at the same speed and the coefficient of friction between the road and the tires is the same, what will its stopping distance be? Explain your results.
29. ** A 20-kg wagon accelerates on a horizontal surface at 0.50 m/s^2 when pulled by a rope exerting a 120-N force on the wagon at an angle of 25° above the horizontal. Determine the magnitude of the effective friction force exerted on the wagon and the effective coefficient of friction associated with this force.
30. ** A crate of mass m sitting on a horizontal floor is attached to a rope that pulls at an angle θ above the horizontal. The coefficient of static friction between the crate and floor is μ_s. (a) Construct a force diagram for the crate when being pulled by the rope but not sliding. (b) Determine an expression for the smallest force that the rope needs to exert on the crate that will cause the crate to start sliding.
31. * EST You absentmindedly leave your book bag on the top of your car. Estimate the safe acceleration of the car needed for the bag to stay on the roof. Describe the assumptions that you made.
32. * Block 1 is on a horizontal surface with a 0.29 coefficient of kinetic friction between it and the surface. A string attached to the front of block 1 passes over a light frictionless pulley and down to hanging block 2. Determine the mass of block 2 in terms of block 1 so that the blocks move at constant nonzero speed while sliding.

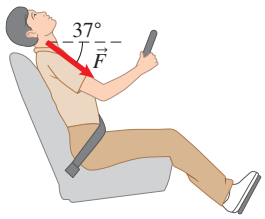
4.4 Skills for analyzing processes involving forces in two dimensions

33. * You want to use a rope to pull a 10-kg box of books up a plane inclined 30° above the horizontal. The coefficient of kinetic friction is 0.30. What force do you need to exert on the other end of the rope if you want to pull the box (a) at constant speed and (b) with a constant acceleration of 0.50 m/s^2 up the plane? The rope pulls parallel to the incline.
34. * A car with its wheels locked rests on a flatbed of a tow truck. The flatbed's angle with the horizontal is slowly increased. When the angle becomes 40°, the car starts to slide. Determine the coefficient of static friction between the flatbed and the car's tires.
35. * **Olympic skier** Olympic skier Tina Maze skis down a steep slope that descends at an angle of 30° below the horizontal. The coefficient of sliding friction between her skis and the snow is 0.10. Determine Maze's acceleration, and her speed 6.0 s after starting.
36. * **Another Olympic skier** Bode Miller, 80-kg downhill skier, descends a slope inclined at 20°. Determine his acceleration if the coefficient of friction is 0.10. How would this acceleration compare to that of a 160-kg skier going down the same hill? Justify your answer using sound physics reasoning.
37. * A book slides off a desk that is tilted 15° relative to the horizontal. What information about the book or the desk does this number provide?
38. * **Equation Jeopardy 2** The two sets of equations below are the horizontal x- and vertical y-component forms of Newton's second law applied to two physical processes. In both cases, solve for the unknowns. Then work backward and construct a force diagram for the object of interest and invent a problem for which the equations could be an answer (there are many possibilities). Note the difference between N (unit of force, newton) and N (symbol for a normal force).

$$(5.0\text{ kg})a_x = (50\text{ N})\cos 30° + N\cos 90° - 0.5N\cos 0° + (5.0\text{ kg})(9.8\text{ N/kg})\cos 90°$$

$$(5.0\text{ kg})0 = (-50\text{ N})\sin 30° + N\sin 90° + 0.5N\sin 0° - (5.0\text{ kg})(9.8\text{ N/kg})\sin 90°$$

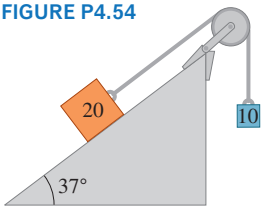
    (b) This process involves an object on an incline.



$$(5.0\text{ kg})0 = +F\cos 0° + N\cos 90° - 0.50N\cos 0° - (5.0\text{ kg})(9.8\text{ N/kg})\cos 60°$$

$$(5.0\text{ kg})0 = +F\sin 0° + N\sin 90° - 0.50N\sin 0° - (5.0\text{ kg})(9.8\text{ N/kg})\sin 60°$$

39. * Helge, Steve, and Heidi are sitting on a sled on a slope covered with a hard snow. The sled is stationary. The friends have different suggestions for how to make the sled start moving:
Helge: If one of us gets off, the sled will start moving.
Steve: We should invite another person to join us, and then the sled will start moving.
Heidi: We should get off the sled, polish the bottom of the sled to make it smoother, and sit back down on it. The sled will then start moving.
Comment on the students' suggestions and decide whose reasoning is correct. Explain using physics concepts, including appropriate diagrams, why those who were incorrect said what they did, and indicate what part of their reasoning was correct.
40. * When traveling on an airplane you get meals on a serving tray that has large coefficients of static and kinetic friction between the tray and dishes on it. For each case below, draw a force diagram for a cup on a serving tray as seen by a stationary observer on Earth and assuming the airplane is moving from left to right. Assume also that the tray is parallel to the velocity of the airplane.
    (a) The airplane is flying horizontally at constant speed; the cup is at rest on the tray.
    (b) The airplane is on a runway and slowing down; the cup is at rest on the tray.
    (c) The airplane is on a runway and slowing down; the cup is sliding. Next to the force diagram draw an arrow that shows the velocity of the cup relative to the airplane.
    (d) The airplane is on a runway and speeding up; the cup is at rest on the tray.
    (e) The airplane is descending at constant speed at an angle 30° with respect to horizontal; the cup is at rest on the tray.
    (f) The airplane is slowing down and descending at an angle 30° with respect to horizontal; the cup is at rest on the tray.



41. **Skier** A 52-kg skier starts at rest and slides 30 m down a hill inclined at 12° relative to the horizontal. List five quantities that describe the motion of the skier, and solve for three of them (at least one should be a kinematics quantity).
42. * **Ski rope tow** You agree to build a backyard rope tow to pull your siblings up a 20-m slope that is tilted at 15° relative to the horizontal. You must choose a motor that can pull your 40-kg sister up the hill. Determine the force that the rope should exert on your sister to pull her up the hill at constant velocity.
43. * **Soapbox racecar** A soapbox derby racecar starts at rest at the top of a 301-m-long track tilted at an average 4.8° relative to the horizontal. If the car's speed were not reduced by any structural effects or by friction, how long would it take to complete the race? What is the speed of the car at the end of the race?
44. * A person is pushing two carts that are connected with a metal bar so that the carts are moving at constant acceleration 0.2 m/s^2. The masses of the carts are 100 kg and 180 kg, and the mass of the connecting bar is 60 kg. Determine (a) the force that the bar exerts on the smaller cart and (b) the force that the bigger cart exerts on the bar. Assume that the friction forces are negligible.
45. * BIO **Whiplash experience** A car sitting at rest is hit from the rear by a semi-trailer truck moving at 13 m/s. The car lurches forward with an acceleration of about 300 m/s^2. **Figure P4.45** shows an arrow that represents the force that the neck muscle exerts on the head so that it accelerates forward with the body instead of flipping backward. If the head has a mass of 4.5 kg, what is the horizontal component of the force $\vec{F}$ required to cause this head acceleration? If $\vec{F}$ is directed 37° below the horizontal, what is the magnitude of $\vec{F}$?

FIGURE P4.45

46. **Iditarod race practice** The dogs of four-time Iditarod Trail Sled Dog Race champion Jeff King pull two 100-kg sleds that are connected by a rope. The sleds move on an icy surface. The dogs exert a 240-N force on the rope attached to the front sled. Find the acceleration of the sleds and the force the rope between the sleds exerts on each sled. The front rope pulls horizontally.
47. ** You pull a rope oriented at a 37° angle above the horizontal. The other end of the rope is attached to the front of the first of two wagons that have the same 30-kg mass. The rope exerts a force of magnitude T_1 on the first wagon. The wagons are connected by a second horizontal rope that exerts a force of magnitude T_2 on the second wagon. Determine the magnitudes of T_1 and T_2 if the acceleration of the wagons is 2.0 m/s^2.
48. * Rope 1 pulls horizontally, exerting a force of 45 N on an 18-kg wagon attached by a second horizontal rope to a second 12-kg wagon. Make a list of physical quantities you can determine using this information, and solve for three of them, including one kinematics quantity.
49. * Three sleds of masses m_1, m_2, m_3 are on a smooth horizontal surface (ice) and connected by ropes, so that if you pull the rope connected to sled 1, all the sleds start moving. Imagine that you exert a force of a known magnitude on the rope attached to the first sled. What will happen to all of the sleds? Provide information about their accelerations and all the forces exerted on them. What assumptions did you make?
50. ** Repeat Problem 4.49, only this time with the sleds on a slope inclined at θ.
51. * A skier is moving down a snowy hill with an acceleration of 0.4 m/s^2. The angle of the slope is 5° to the horizontal. What is the acceleration of the same skier when she is moving down a hill with a slope of 10°? Assume the coefficient of kinetic friction is the same in both cases.
52. ** A person holds a 200-g block that is connected to a 250-g block by a string going over a light pulley with no friction in the bearing (an Atwood machine). After the person releases the 200-g block, it starts moving upward and the heavier block descends. (a) What is the acceleration of each block? (b) What is the force that the string exerts on each block? (c) How long will it take each block to traverse 1.0 m?
53. ** Two blocks of masses m_1 and m_2 are connected to each other on an Atwood machine. A person holds one of the blocks with her hand. When the system is released, the heavier block moves down with an acceleration of 2.3 m/s^2 and the lighter object moves up with an acceleration of the same magnitude. What is one possible set of masses for the blocks?
54. ** The 20-kg block shown in **Figure P4.54** accelerates down and to the left, and the 10-kg block accelerates up. Find the magnitude of this acceleration and the force that the cable exerts on a block. There is no friction between the block and the inclined plane, and the pulley is frictionless and light.

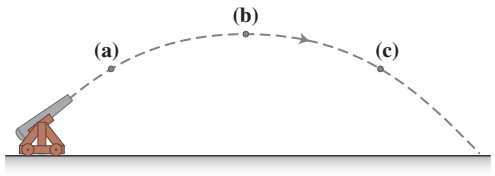
FIGURE P4.54

4.5 Projectile motion

55. * A squirrel jumps off a roof in the horizontal direction. The origin of the coordinate system is at the point where the squirrel leaves the roof. Complete **Table P4.55** by drawing crosses in the cells that correctly connect the physical quantities in the first column that describe the motion of the squirrel and the descriptions of what is happening to these quantities while the squirrel is in flight. Consider the squirrel as a point-like object and assume that the resistive force exerted by the air is negligible.
56. * A frog jumps at an angle 30° above the horizontal. The origin of the coordinate system is at the point where the frog leaves the ground. Complete Table P4.55 by drawing check marks in the cells that correctly connect the quantities in the first column that describe the motion of the frog and the descriptions of what is happening to these quantities while the frog is moving. Consider the frog as a point-like object and assume that the resistive force exerted by the air is negligible.

TABLE P4.55

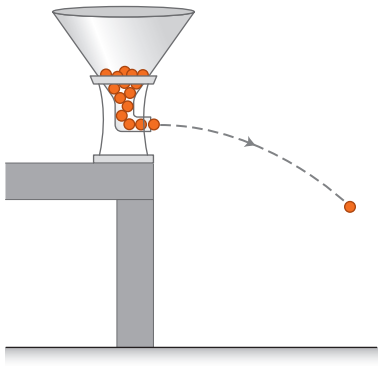
Physical quantity	Remains constant	Is changing	Increases only	Decreases only	Increases, then decreases	Decreases, then increases
x-coordinate magnitude						
y-coordinate magnitude						
Direction of velocity						
Magnitude of velocity						
Direction of acceleration						
Magnitude of acceleration						



57. A bowling ball rolls off a table. Draw a force diagram for the ball when on the table and when in the air at two different positions.
58. * A tennis ball is served from the back line of the court such that it leaves the racket 2.4 m above the ground in a horizontal direction at a speed of 22.3 m/s (50 mi/h). (a) Will the ball cross a 0.91-m-high net 11.9 m in front of the server? (b) Will the ball land in the service court, which is within 6.4 m of the net on the other side of the net?
59. * **Equation Jeopardy 3** The equations below describe a projectile's path. Solve for the unknowns and then invent a process that the equations might describe. There are many possibilities.

$$x = 0 + (20\ \text{m/s})(\cos 0°)t$$

$$0 = 8.0\ \text{m} + (20\ \text{m/s})(\sin 0°)t - \frac{1}{2}(9.8\ \text{m/s}^2)t^2$$

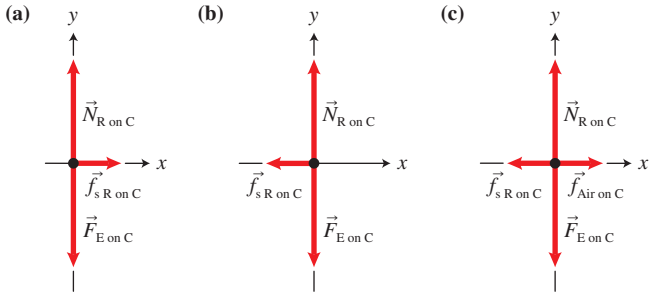


60. * EST An airplane is delivering food to a small island. It flies 100 m above the ground at a speed of 160 m/s. (a) Where should the parcel be released so it lands on the island? Neglect air resistance. (b) Estimate whether you should release the parcel earlier or later if there is air resistance. Explain.
61. A ball moves in an arc through the air (see **Figure P4.61**). Construct a force diagram for the ball when at positions (a), (b), and (c). Ignore the resistive force exerted by the air on the ball.

FIGURE P4.61

62. A marble is thrown as a projectile at an angle above the horizontal. Draw its path during the flight. Choose six different positions along the path so that one of them is at the highest point. For each position, indicate the direction of the marble's velocity, acceleration, and all of the forces exerted on it by other objects. Ignore the resistive force exerted by the air on the marble.
63. * Marbles are exiting a container through a horizontal nozzle positioned 1.3 m above sandy ground (see **Figure P4.63**). You notice that all the marbles land between 0.25 m and 0.45 m from the point directly below the end of the nozzle. How do you explain this observation? What can you determine based on the data given in the problem? Indicate any assumptions that you made.

FIGURE P4.63

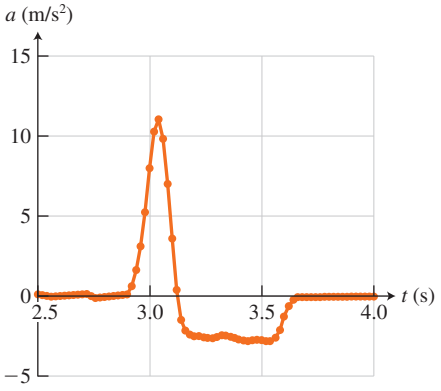


64. * **Robbie Knievel ride** On May 20, 1999, Robbie Knievel easily cleared a narrow part of the Grand Canyon during a world-record–setting long-distance motorcycle jump—69.5 m. He left the jump ramp at a 10° angle above the horizontal. How fast was he traveling when he left the ramp? Indicate any assumptions you made.
65. * Daring Darless wishes to cross the Grand Canyon of the Snake River by being shot from a cannon. She wishes to be launched at 60° relative to the horizontal so she can spend more time in the air waving to the crowd. With what minimum speed must she be launched to cross the 520-m gap?
66. * A football punter wants to kick the ball so that it is in the air for 4.0 s and lands 50 m from where it was kicked. At what angle and with what initial speed should he kick the ball? Assume that the ball leaves 1.0 m above the ground.
67. * If you shoot a cannonball from the same cannon first at 30° and then at 60° relative to the horizontal, which orientation of the cannon will make the ball go farther? How do you know? Under what circumstances is your answer valid? Explain.
68. When you actually perform the experiment described in Problem 4.67, the ball shot at a 60° angle lands closer to the cannon than the ball shot at a 30° angle. Explain why this happens.
69. * You can shoot an arrow straight up so that it reaches the top of a 25-m-tall building. (a) How far will the arrow travel if you shoot it horizontally while pulling the bow in the same way? The arrow starts 1.45 m above the ground. (b) Where do you need to put a target that is 1.45 m above the ground in order to hit it if you aim 30° above the horizontal? (c) What assumptions did you make?
70. * Robin Hood wishes to split an arrow already in the bull's-eye of a target 40 m away. If he aims directly at the arrow, by how much will he miss? The arrow leaves the bow horizontally at 40 m/s.

4.6 Starting and stopping a car

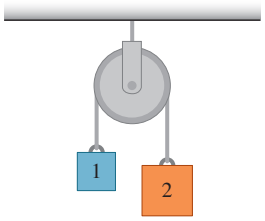
71. * Three force diagrams for a car on a road are shown in **Figure P4.71**. Indicate as many situations as possible for the car in terms of its velocity and acceleration at that instant for each diagram.

FIGURE P4.71



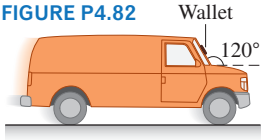
72. * A minivan of mass 1560 kg starts at rest and then accelerates at 2.0 m/s^2. (a) What is the object exerting the force on the minivan that causes it to accelerate? What type of force is it? (b) Air resistance and other opposing resistive forces are 300 N. Determine the magnitude of the force that causes the minivan to accelerate in the forward direction.

General Problems



73. ** A daredevil motorcycle rider hires you to plan the details for a stunt in which she will fly her motorcycle over six school buses. Assume the ride starts on flat ground. Provide as much information as you can to help the rider successfully complete the stunt.
74. * Emily pulls a 5-kg block across a rough horizontal surface, exerting a constant force on the block. The magnitude of the force is initially 5 N, and the block moves at a constant velocity of 2 m/s. While the block is moving, Emily instantly increases the force to 10 N. How will the block move now?
Andrew says: The block will move at a constant velocity of 4 m/s because it was initially moving with constant velocity and the final force is two times larger than the initial force.
Jasit says: The block will move at a constant acceleration of 2 m/s^2 because the sum of the forces exerted on the block is 10 N and the mass of the block is 5 kg.
Mary says: The block will move at a constant acceleration of 1 m/s^2 because the sum of the forces exerted on the block is 5 N and the mass of the block is 5 kg.
Explain which student is correct. Also comment on what is incorrect about the other statements.
75. * EST You abruptly push a 1.7-kg book along a table and let go. The book comes to a stop after a short distance. **Figure P4.75** shows the acceleration-versus-time graph of the book as recorded by a motion detector. Estimate the following quantities: (a) the coefficient of kinetic friction between the book and the table and (b) the maximum force exerted by your hand on the book.

FIGURE P4.75



76. ** EST In the situation of Problem 4.75, estimate (a) the maximum speed of the book and (b) the clock reading when your hand stopped exerting the force on the book.
77. * EST Estimate the range of the horizontal force that a sidewalk exerts on you during every step while you are walking. Indicate clearly how you made the estimate.
78. * Two blocks of masses m_1 and m_2 hang at the ends of a string that passes over the very light pulley with low friction bearings shown in **Figure P4.78**. Determine an expression in terms of the masses and any other needed quantities for the magnitude of the acceleration of each block and the force that the string exerts on each block. Apply the equation for two cases: (a) the blocks have the same mass, but one is positioned lower than the other and (b) the blocks have different masses, but the heavier block is positioned higher than the light one. What assumptions did you make?

FIGURE P4.78

79. * A 3.5-kg object placed on an inclined plane (angle 30° above the horizontal) is connected by a string going over a pulley to a 1.0-kg hanging block. (a) Determine the acceleration of the system if there is no friction between the object and the surface of the inclined plane. (b) Determine the magnitude of the force that the string exerts on both objects.
80. ** A 3.5-kg object placed on an inclined plane (angle 30° above the horizontal) is connected by a string going over a pulley to a 1.0-kg object. Determine the acceleration of the system if the coefficient of static friction between object 1 and the surface of the inclined plane is 0.30 and equals the coefficient of kinetic friction.
81. ** An object of mass m_1 placed on an inclined plane (angle θ above the horizontal) is connected by a string going over a pulley to a hanging object of mass m_2. Determine the acceleration of the system if the coefficient of static friction between object 1 and the surface of the inclined plane is μ_s, and the coefficient of kinetic friction is μ_k. If the problem has multiple answers, explore all of them.
82. ** You are driving at a reasonable constant velocity in a van with a windshield tilted 120° relative to the horizontal (see **Figure P4.82**). As you pass under a utility worker fixing a power line, his wallet falls onto the windshield. Determine the acceleration needed by the van so that the wallet stays in place. When choosing your coordinate axes, remember that you want the wallet's acceleration to be horizontal rather than vertical. What assumptions and approximations did you make?

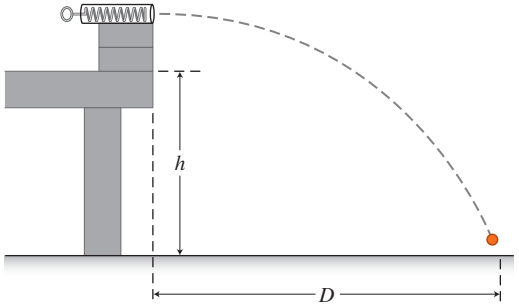


FIGURE P4.82

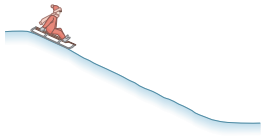
83. * EST Figure P4.19c (from Problem 4.19 above) shows acceleration-versus-time graphs for two fan carts. For each cart, estimate (a) the final velocity of the cart and (b) the distance traveled by the cart while it was speeding up. In both experiments the cart started to move from rest. Indicate any assumptions that you made.
84. * In the situation of Problem 2.71 (Chapter 2) and using the data in the accompanying table, determine the coefficient of kinetic friction between Piglet and the wooden floor.
85. * You push a small box so that it starts moving with a speed of 1 m/s along a rough table. After 1 m, the box reaches the edge of the table and lands on the floor 20 cm from the table edge. The surface of the table is 0.8 m above the floor. Determine (a) the coefficient of friction between the box and the table and (b) the speed of the box at the moment it hits the floor.
86. ** Debbie wants to determine the initial speed at which a spring toy shoots a marble. She assumes the toy shoots the marble with the same speed every time. She shoots the marble horizontally from different heights, using different numbers of bricks with equal heights of 20 cm on a table as a support (see **Figure P4.86**). In every experiment she records the number of bricks and the distance D from the table the marble lands (see the table at right). When she finishes collecting the data, she realizes that she has forgotten to measure the distance between the surface of the table and the floor, h. Determine the initial speed of the marble and the distance h using Debbie's data. (Hint: This problem requires linearization. First, express distance D as a function of initial speed of the marble and the height from which the marble is shot. Then rearrange the equation to obtain linear dependence on the height, plot the best-fit line, and determine unknown quantities from the data that you obtained from the graph.)



# of bricks	D (m)
0	0.42
1	0.48
2	0.54
3	0.59
4	0.64

FIGURE P4.86

87. * Your friend has a pie on the roof of his van. You are standing on the ground and observe the van stopping abruptly for a red light. The pie does not slip off the roof. (a) Construct a motion diagram and a force diagram for the pie as the van approaches the red light, from your frame of reference and from the driver's frame of reference. (b) Repeat part (a) for the case when the light turns green. Be sure to specify the observer and identify the other object causing each force. (c) Are the motion diagrams consistent with the force diagrams for each case?
88. * A ledge on a building is 20 m above the ground. A taut rope attached to a 4.0-kg can of paint sitting on the ledge passes up over a pulley and straight down to a 3.0-kg can of nails on the ground. If the can of paint is accidentally knocked off the ledge, what time interval does a carpenter have to catch the can of paint before it smashes on the ground?
89. * You are hired to devise a method to determine the coefficient of friction between the ground and the soles of a shoe and of its competitors. Explain your experimental technique and provide a physics analysis that could be used by others using this method.
90. The mass of a spacecraft is about 480 kg. An engine designed to increase the speed of the spacecraft while in outer space provides 0.09-N thrust at maximum power. By how much does the engine cause the craft's speed to change in 1 week of running at maximum power? Describe any assumptions you made.
91. ** EST A 60-kg Rollerblader rolls 10 m down a 30° incline. When she reaches the level floor at the bottom, she applies the brakes. Use Newton's second law to estimate the distance she will move before stopping. Justify any assumptions you made.
92. Design, perform, and analyze the results of an experiment to determine the coefficient of static friction and the coefficient of kinetic friction between a penny and the cover of this textbook.
93. * **Tell all** A sled starts at the top of the hill shown in **Figure P4.93**. Add any information that you think is reasonable about the process that ensues when the sled goes down the hill and finally stops. Then tell everything you can about this process.

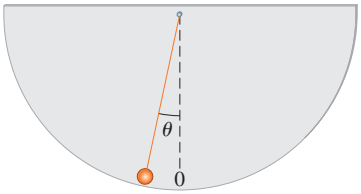


FIGURE P4.93

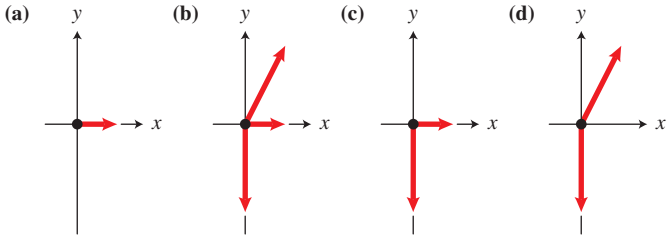
Reading Passage Problems

Professor tests airplane takeoff speed D. A. Wardle, a professor of physics from the University of Auckland, New Zealand, tested the takeoff speed of a commercial airliner. The pilot had insisted that the takeoff speed had to be 232 km/h.[1] To perform the testing experiment, Wardle used a pendulum attached to stiff cardboard (**Figure 4.14**). Prior to takeoff, when the plane was stationary, he marked the position of the pendulum bob on the cardboard to provide a vertical reference line (the dashed line in Figure 4.14). During the takeoff, he recorded the position of the bob at 5-s intervals. The results are shown in the table.

FIGURE 4.14 Wardle's device.

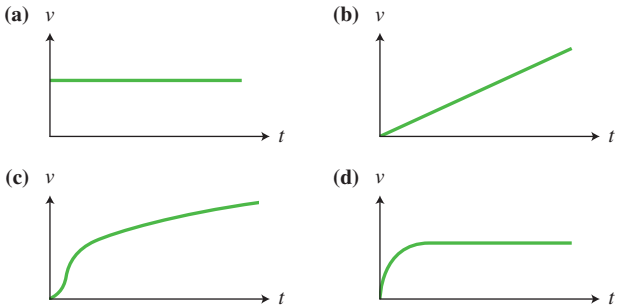


t (s)	θ (°)
0	9.9
5	14.8
10	13.8
15	13.0
20	12.0
25	11.4

Using these data, Professor Wardle determined the acceleration at takeoff to be greater than $g/4$. Then he plotted an acceleration-versus-time graph and used it to find the takeoff speed. It turned out to be about 201 km/h. He was very satisfied—the day was windy, and the speed of the breeze was about 15–20 km/h. Thus the takeoff speed predicted by his simple pendulum was 215–220 km/h, very close to what the pilot said.

94. Choose the best force diagram for the pendulum bob as the plane is accelerating down the runway (**Figure P4.94**).

FIGURE P4.94



95. The professor used which of the following expressions for the pendulum bob acceleration (θ is the angle of the pendulum bob string relative to the vertical)?
(a) $a = g \sin\theta$ (b) $a = g \cos\theta$
(c) $a = g \tan\theta$ (d) None of the choices

96. Approximately when did the peak acceleration occur?
(a) 25 s (b) 20 s (c) 10 s (d) 5 s

97. Approximately when did the peak speed occur?
(a) 25 s (b) 20 s (c) 10 s (d) 5 s

98. Choose the best velocity-versus-time graph below for the airplane (**Figure P4.98**).

FIGURE P4.98

[1]The information is taken from the article by D. A. Wardle "Measurement of aeroplane takeoff speed and cabin pressure" published in *The Physics Teacher*, 37, 410–411 (1999).

Ski jumping in Vancouver The 2010 Olympic ski jumping competition was held at Whistler Mountain near Vancouver. During a jump, a skier starts near the top of the in-run, the part down which the skier glides at increasing speed before the jump. The Whistler in-run is 116 m long and for the first part is tilted down at about 35° below the horizontal. There is then a curve that transitions into a take-off ramp, which is tilted 11° below the horizontal. The skier flies off this ramp at high speed, body tilted forward and skis separated (**Figure 4.15**). This position exposes a large surface area to the air, which creates lift, extends the time of the jump, and allows the jumper to travel farther. In addition, the skier pushes off the exit ramp of the in-run to get a vertical component of velocity when leaving the ramp. The skier lands 125 m or more from the end of the in-run. The landing surface has a complex shape and is tilted down at about 35° below the horizontal. The skier moves surprisingly close (2 to 6 m) above the snowy surface for most of the jump. The coefficient of kinetic friction between the skis and the snow on the in-run is about 0.05 ± 0.02, and skiers' masses are normally small—about 60 kg. We can make some rough estimates about an idealized ski jump with an average in-run inclination of $(35° + 11°)/2 = 23°$.

FIGURE 4.15 A ski jumper exposes a large surface area to the air in order to get more lift.

99. Which answer below is closest to the magnitude of the normal force that the idealized in-run exerts on the 60-kg skier?
(a) 590 N (b) 540 N (c) 250 N (d) 230 N

100. Which numbers below are closest to the magnitudes of the kinetic friction force and the component of the gravitational force parallel to the idealized inclined in-run?
(a) 30 N, 540 N (b) 27 N, 540 N (c) 12 N, 540 N
(d) 30 N, 230 N (e) 27 N, 230 N (f) 12 N, 230 N

101. Which answers below are closest to the magnitude of the skier's acceleration while moving down the idealized in-run and to the skier's speed when leaving its end?
(a) 9.8 m/s^2, 48 m/s (b) 4.3 m/s^2, 32 m/s (c) 4.3 m/s^2, 28 m/s
(d) 3.4 m/s^2, 32 m/s (e) 3.4 m/s^2, 28 m/s

102. Assume that the skier left the ramp moving horizontally. Treat the skier as a point-like particle and assume the force exerted by air on him is minimal. If he landed 125 m diagonally from the end of the in-run, and the landing region beyond the in-run was inclined 35° below the horizontal for its entire length, which answer below is closest to the time interval that he was in the air?
(a) 1.9 s (b) 2.4 s (c) 3.1 s
(d) 3.8 s (e) 4.3 s

103. Using the same assumptions as stated in Problem 4.102, which answer below is closest to the jumper's speed when leaving the in-run?
(a) 37 m/s (b) 31 m/s (c) 27 m/s
(d) 24 m/s (e) 21 m/s

104. Which factors below would keep the skier in the air longer and contribute to a longer jump?
1. The ramp at the end of the in-run is level instead of slightly tilted down.
2. The skier extends his body forward and positions his skis in a V shape.
3. The skier has wider and longer than usual skis.
4. The skier pushes upward off the end of the ramp at the end of the in-run.
5. The skier crouches in a streamline position when going down the in-run.

(a) 1 (b) 5 (c) 1, 3, 5
(d) 2, 3, 4 (e) 1, 2, 4, 5 (f) 1, 2, 3, 4, 5

Circular Motion

- **Why do pilots sometimes black out when pulling out of a steep dive?**
- **Are astronauts really "weightless" while in orbit?**
- **Why do you tend to slide across the seat of your car when making a sharp turn?**

Kruti Patel, a civilian test pilot, wears a special flight suit to prevent dizziness, disorientation, and possibly passing out as she comes out of a steep dive. These symptoms characterize a blackout, which can occur when the head and brain do not receive a sufficient amount of blood. Why would pulling out of a dive cause a blackout, and how does a special suit prevent it from occurring? Our study of circular motion in this chapter will help us understand blackouts and other interesting phenomena.

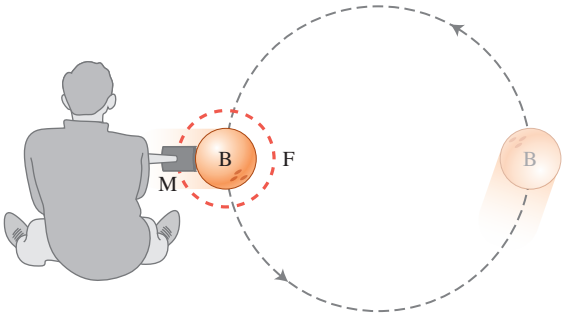
BE SURE YOU KNOW HOW TO:

- Find the direction of acceleration using a motion diagram (Section 2.7).
- Draw a force diagram (Section 3.1).
- Use a force diagram to help apply Newton's second law in component form (Sections 4.1 and 4.2).

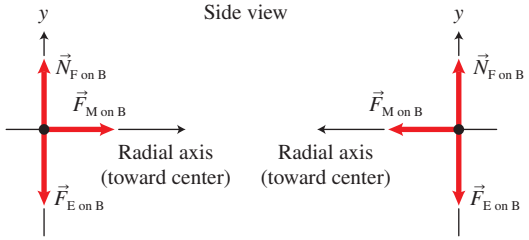
IN PREVIOUS CHAPTERS we studied motion in situations in which the sum of the forces exerted on a system had a constant magnitude and direction. More often, the forces exerted on an object continually change direction and magnitude as time passes. In this chapter we will focus on circular motion. It is the simplest example of motion in which the sum of the forces exerted on a system by other objects continually changes.

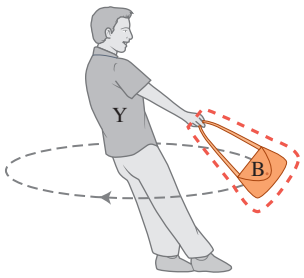
5.1 Qualitative dynamics of circular motion

Think of a person riding on a Ferris wheel or a merry-go-round, a car making a turn, or a swinging pendulum bob. All of these objects have one thing in common: they do not follow a straight line but move in a circle or a part of a circle (an arc). To study the motion of objects along a circular path, we will start with the simple case of an object moving around a circle such that the time to complete one full circle does not change—that is, the object moves with constant speed. An example of such an object is a car on a circular track whose speedometer reads 55 mph. We will also consider the object to be a point-like object. These assumptions allow us to model circular motion in the simplest way.

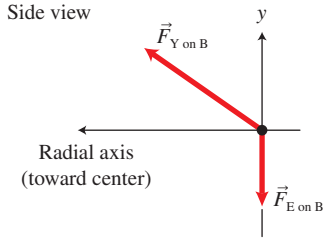


OBSERVATIONAL EXPERIMENT TABLE 5.1





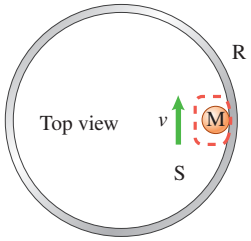
Forces exerted on an object moving in a circle at constant speed

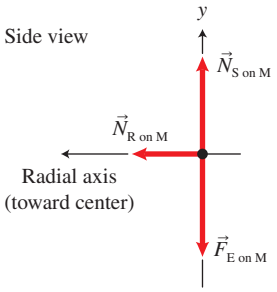


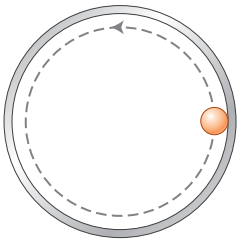
VIDEO OET 5.1

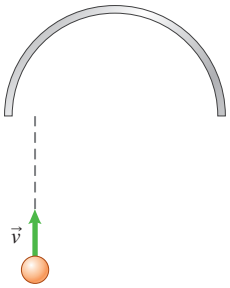
Observational experiment	Analysis
Experiment 1. A bowling ball is rolled toward you over a smooth floor. You are asked to tap it with a mallet to make the ball roll in a circle with constant speed. You find that directing the mallet taps along the desired circular path doesn't work; the ball rolls wide. The only thing that works is to tap *directly toward the center of the desired circle.*	There are three objects interacting with the bowling ball: Earth, the floor, and the mallet. We assume that the force exerted by the floor is perpendicular to the floor's surface. The force diagrams for the ball at two locations are shown below. We see that at each location the sum of the forces points toward the center of the circle.
Experiment 2. You hold a bag by the handle and swing it in a horizontal circle at constant speed. You observe that your arms pulling the bag are angled down with respect to the horizontal.	Two forces are exerted on the bag as it moves around the circle: Earth pulls downward, and you pull at an angle with the vertical. The vertical component of the force that you exert on the bag must balance the force that Earth exerts on it because the bag does not accelerate in the vertical direction. Consequently, the sum of these two forces again points toward the center of the circle.

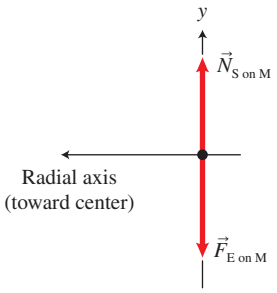
Pattern

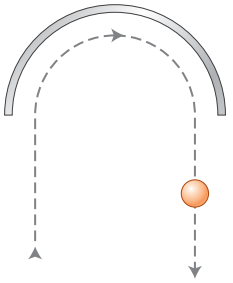












In each case, as shown in the force diagrams, the sum of the forces exerted on the circling object points directly toward the center of the circle.

We can therefore propose a hypothesis: when an object is moving in a circle, the sum of all the forces exerted on it by other objects is directed toward the center of the circle. (We assume the speed of the object is constant.) Let's test this hypothesis with some more experiments.

TESTING EXPERIMENT TABLE 5.2

Does the sum of the forces exerted on an object moving at constant speed in a circle point toward the center of the circle?

VIDEO TET 5.2

Testing experiment	Prediction	Outcome
Experiment 1. You roll a marble against the inside wall of a metal ring sitting on a smooth surface. 	The force diagram for the marble is shown below.  The vertical force components add to zero. The sum of the forces points along the radial axis toward the center of the circle. Thus we predict that the marble will roll along the wall of the ring following the circle.	As you can see in the video, this is exactly what happens. The marble rolls inside the ring following the circle. 
Experiment 2. You roll a marble at constant speed toward a semicircular metal ring sitting on a smooth surface. 	When the marble rolls toward the ring, the sum of the forces exerted on it is zero, so we predict that it will move in a straight line with constant velocity. When it reaches the ring, the sum of the forces will point toward the center of the ring, so we predict it will follow the ring as in Experiment 1. Once the marble reaches the end of the ring, it should continue in a straight line as before. 	The video of the experiment shows that our prediction matches the outcome. 

Conclusion

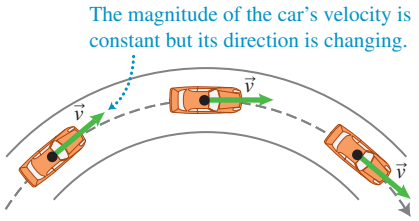
The outcomes of both experiments are consistent with the pattern of the sum of the forces exerted on an object moving at constant speed in a circle pointing toward the center.

Now we need to explain why this pattern exists. Why would the sum of the forces exerted on an object moving in a circle at constant speed point toward the center of the circle? According to Newton's second law, the sum of the forces is in the same direction as the object's acceleration. Therefore, the object's acceleration should also point

toward the center of the circle. We will learn how to determine the direction of acceleration during circular motion at constant speed in the next section.

REVIEW QUESTION 5.1 How do we know that the sum of the forces exerted on an object moving in a circle at constant speed points toward the center of the circle?

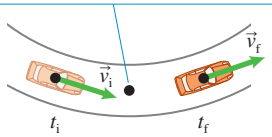
5.2 Analyzing velocity change for circular motion



Consider the motion of the car shown in **Figure 5.1** as it travels at constant speed around a circular track. The instantaneous velocity of the car is tangent to the circle at every point. Recall from Chapter 2 that an object has acceleration if its velocity changes—in magnitude, in direction, or in both. Even though the car is moving at constant speed, it is accelerating because the *direction* of its velocity changes from moment to moment.

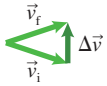
To estimate the direction of acceleration of any object (including that of the car) while passing a particular point on its path (see Physics Tool Box 5.1), we use the **velocity change method**. Consider a short time interval $\Delta t = t_f - t_i$ during which the car passes that point. The velocity arrows $\vec{v}_i$ and $\vec{v}_f$ represent the initial and final velocities of the car, a little before and a little after the point (note that the velocity arrows are tangent to the curve in the direction of motion; this is Step 1 in the Tool Box). The velocity change vector is $\Delta\vec{v} = \vec{v}_f - \vec{v}_i$. You can think of $\Delta\vec{v}$ as the vector that you need to add to the initial velocity $\vec{v}_i$ in order to get the final velocity $\vec{v}_f$, that is, $\vec{v}_i + \Delta\vec{v} = \vec{v}_f$. Rearranging this, we get $\Delta\vec{v} = \vec{v}_f - \vec{v}_i$ (the change in velocity).

To estimate $\Delta\vec{v}$, place the $\vec{v}_i$ and $\vec{v}_f$ arrows tail to tail (Step 2 in the Tool Box) without changing their magnitudes or directions. $\Delta\vec{v}$ starts at the head of $\vec{v}_i$ and ends at the head of $\vec{v}_f$. The car's acceleration $\vec{a}$ is in the direction of the $\Delta\vec{v}$ arrow (Step 3 in the Tool Box) and is the ratio of the velocity change and the time interval needed for that change:



$$\vec{a} = \frac{\Delta\vec{v}}{\Delta t}$$

FIGURE 5.1 Since the direction of the velocity is changing, the car is accelerating.

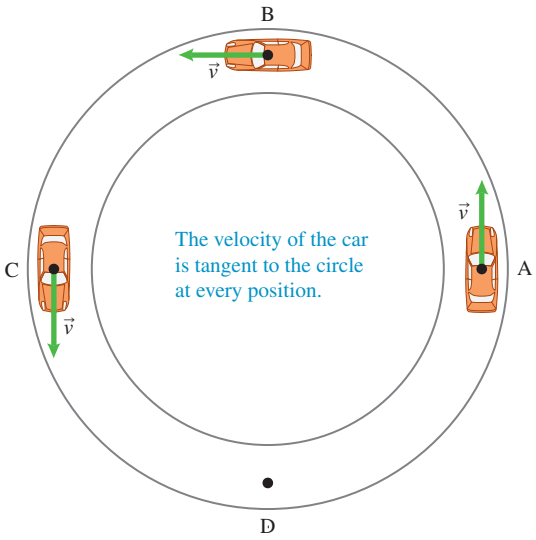


PHYSICS TOOL BOX 5.1 Estimating the direction of acceleration during two-dimensional motion

1. Choose the point at which you want to determine the direction of acceleration and draw velocity vectors at equal distances before and after the point.

2. Place the $\vec{v}_i$ and $\vec{v}_f$ arrows tail to tail. Draw a $\Delta\vec{v}$ arrow from the head of $\vec{v}_i$ to the head of $\vec{v}_f$.

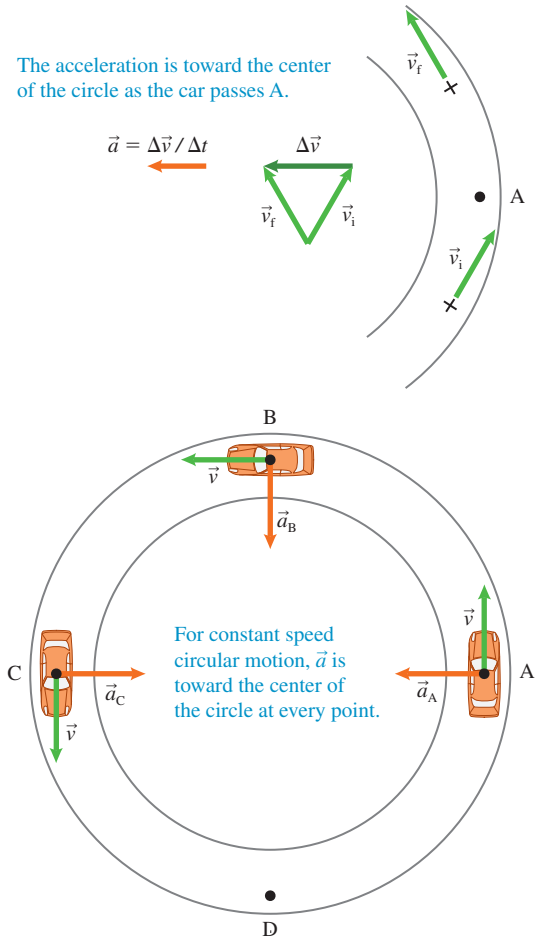
$\vec{v}_i + \Delta\vec{v} = \vec{v}_f$
or
$\Delta\vec{v} = \vec{v}_f - \vec{v}_i$



3. The acceleration arrow $\vec{a}$ is in the direction of $\Delta\vec{v}$.

$$\vec{a} = \frac{\Delta\vec{v}}{\Delta t} = \frac{\vec{v}_f - \vec{v}_i}{t_f - t_i}$$

TIP When using this diagrammatic method to estimate the direction of acceleration at a particular point during circular motion, make sure that you choose initial and final points at the same distance before and after the point at which you are estimating the acceleration direction. Draw long velocity arrows so that when you put them tail to tail, you can clearly see the direction of the velocity change arrow. Also, be sure that the velocity change arrow points from the head of the initial velocity to the head of the final velocity. Note that this method of estimating the direction of acceleration works for any motion, not just circular.



CONCEPTUAL EXERCISE 5.1 Direction of a racecar's acceleration

Determine the direction of the racecar's acceleration at points A, B, and C in the figure below as the car travels at constant speed on the circular path.

Sketch and translate A top view of the car's path is shown above. We are interested in the car's acceleration as it passes points A, B, and C.

Simplify and diagram To find the direction of the car's acceleration at each point, we use the velocity change method (shown for point A above, right). When done for all three points, notice that a pattern emerges: the acceleration at different points along the car's path has a different direction, but in every case it points toward the center of the circular path.

Try it yourself Find the direction of the car's acceleration at point D on the track.

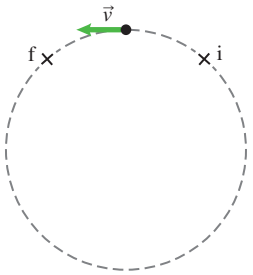
Answer The car's acceleration points toward the center of the circle here as well.

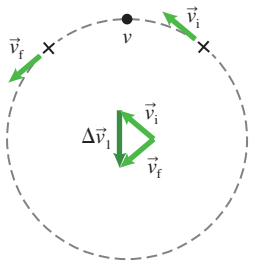
In Conceptual Exercise 5.1 we found an important pattern: when an object is moving in a circle at *constant speed,* its acceleration at any position points toward the center of the circle. This acceleration is called **radial acceleration** because it points along the radius of the circle.

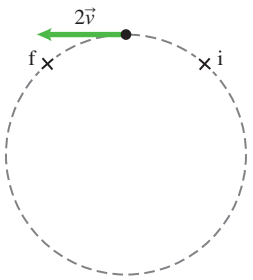
The radial direction of acceleration is due to the fact that the direction of the velocity continuously changes. In Section 5.1 we found that the sum of the forces exerted on an object moving in a circle points toward the center of the circle at every point. This force finding makes sense now—for one object to continuously change its direction of motion, another object needs to exert a force on the first object. We can think of this force as a "hand" physically turning the velocity vector so that it is always tangent to the circle. Once this "hand" is removed, the object continues to move in a straight line, as we observed in Experiment 2 in Table 5.2. Our new knowledge concerning circular motion is consistent with Newton's second law.

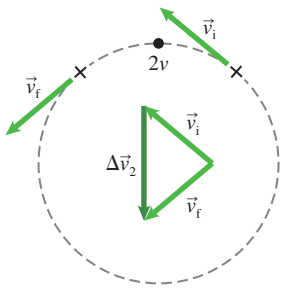
REVIEW QUESTION 5.2 Why is it true that when an object is moving in a circle at constant speed, its acceleration at any point is perpendicular to its instantaneous velocity?

5.3 Radial acceleration and period



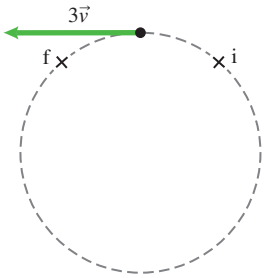


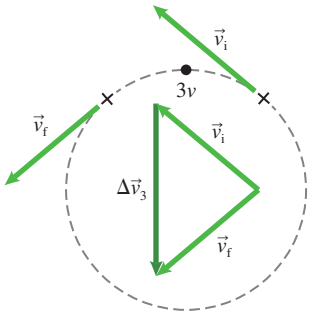




So far we have learned about the direction of the acceleration of an object moving in a circle at constant speed. Let's now determine the magnitude of the object's acceleration. We will begin by thinking about factors that might affect its acceleration.

Imagine a car following the circular curve of a highway. Our experience indicates that the faster a car moves along a highway curve, the greater the risk that the car will skid off the road. So the car's speed v matters. Also, the tighter the turn, the greater the risk that the car will skid. So the radius r of the curve also matters. But how exactly do speed and radius combine in the mathematical expression for radial acceleration?





Dependence of acceleration on speed

Let's begin by investigating how an object's acceleration depends on speed. In Observational Experiment **Table 5.3**, we use the diagrammatic velocity change method to investigate how the acceleration differs for objects moving at speeds v, $2v$, and $3v$ while traveling along the same circular path of radius r.

OBSERVATIONAL EXPERIMENT TABLE 5.3 How does acceleration depend on the object's speed?

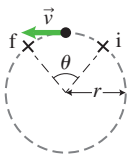
Observational experiment	Analysis
Experiment 1. An object moves in a circle at constant speed. 	The acceleration is toward the center of the circular path.  $a_1 = \frac{\Delta v_1}{\Delta t_1}$
Experiment 2. An object moves in the same circle at a constant speed that is twice as fast as in Experiment 1. 	When the object moves twice as fast between the same two points on the circle, the velocity change doubles. In addition, the velocity change occurs in one-half the time interval since it is moving twice as fast. Hence, the acceleration increases by a factor of 4.  $a_2 = \frac{\Delta v_2}{\Delta t_2} = \frac{2\Delta v_1}{\Delta t_1/2} = 4\frac{\Delta v_1}{\Delta t_1}$

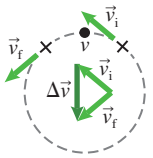
(CONTINUED)

Observational experiment	Analysis
Experiment 3. An object moves in the same circle at a constant speed that is three times as fast as in Experiment 1. 	Tripling the speed triples the velocity change and reduces to one-third the time interval needed to travel between the points. The acceleration increases by a factor of 9.  $a_3 = \frac{\Delta v_3}{\Delta t_3} = \frac{3\Delta v_1}{\Delta t_1 / 3} = 9\frac{\Delta v_1}{\Delta t_1}$

Pattern

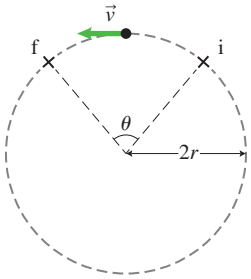
We find that doubling the speed of the object results in a fourfold increase of its radial acceleration; tripling the speed leads to a ninefold increase. Therefore, the radial acceleration of the object is proportional to its speed squared: $a_r \propto v^2$



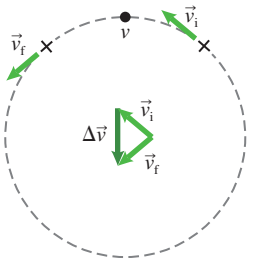


From the pattern in Table 5.3 we conclude that the magnitude of radial acceleration is proportional to the speed squared. We can express this pattern mathematically:

$$a_r \propto v^2 \tag{5.1}$$



Dependence of acceleration on radius



To find how the magnitude of acceleration of an object moving in a circle at constant speed depends on the radius r of the circle, we use the velocity change method to consider two objects moving with the same speed but on circular paths of different radii (Observational Experiment **Table 5.4**). For simplicity, we make one circle twice the radius of the other. We arrange to have the same velocity change for the two objects by considering them while moving through the same angle θ (rather than through the same distance).

OBSERVATIONAL EXPERIMENT TABLE 5.4 How does acceleration depend on the radius of the curved path?

Observational experiment	Analysis
Experiment 1. An object moves in a circle of radius r at speed v. Choose two points on the circle to examine the velocity change from the initial to the final location. 	 $a_1 = \frac{\Delta v}{\Delta t_1}$

Observational experiment	Analysis
Experiment 2. An object moves in a circle of radius $2r$ at speed v. Choose two points so that the velocity change is the same as in Experiment 1. This occurs if the radii drawn to the location of the object at the initial position and the final position make the same angle as in Experiment 1.	To have the same velocity change as in Experiment 1, the object has to travel twice the distance because the radius is twice as long. Since the speed of the object is the same as in the first experiment, it takes the object twice as long to travel that distance. Hence, the magnitude of the acceleration is half that in Experiment 1.

$$a_2 = \frac{\Delta v}{\Delta t_2} = \frac{\Delta v}{2\Delta t_1} = \frac{1}{2}a_1$$

Pattern

When an object moves in a circle at constant speed, its radial acceleration decreases by half when the radius of the circular path doubles—the bigger the circle, the smaller the acceleration. Therefore, the radial acceleration of the object is proportional to the inverse of the radius of its circular path:

$$a_r \propto \frac{1}{r}$$

If we carried out the same thought experiment with circular paths of other radii, we would get similar results. The magnitude of the radial acceleration of an object moving in a circular path is inversely proportional to the radius of the circle:

$$a_r \propto \frac{1}{r} \tag{5.2}$$

We now combine the two proportionalities in Eqs. (5.1) and (5.2):

$$a_r \propto \frac{v^2}{r}$$

A detailed mathematical derivation would show that the constant of proportionality is 1. Thus, we can turn this into an equation for the magnitude of the radial acceleration.

Radial acceleration For an object moving at constant speed v on a circular path of radius r, the magnitude of the radial acceleration is

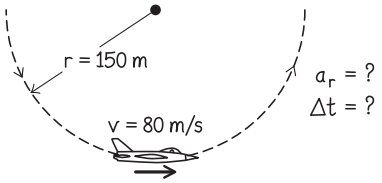
$$a_r = \frac{v^2}{r} \tag{5.3}$$

The acceleration points toward the center of the circle. The units for v^2/r are the correct units for acceleration:

$$\left(\frac{\mathrm{m}^2/\mathrm{s}^2}{\mathrm{m}}\right) = \frac{\mathrm{m}}{\mathrm{s}^2}$$

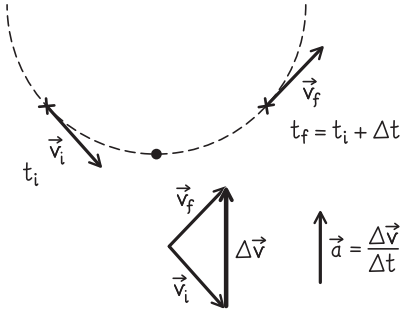
This expression for radial acceleration agrees with our everyday experience. When a car is going around a highway curve at high speed, a large v^2 in the numerator leads to its large acceleration. When it is going around a sharp turn, the small radius r in the denominator also leads to a large acceleration.

Consider a limiting case: when the radius of the circular path is infinite—equivalent to the object moving in a straight line. The velocity of an object moving at constant speed in a straight line is constant, and its acceleration is zero. Notice that the acceleration in Eq. (5.3) is zero if the radius in the denominator is infinite.



TIP Sometimes the radial acceleration is called centripetal acceleration, and the product of radial acceleration and the mass of the object is called centripetal force. We will not use this terminology, as sometimes it makes students think that centripetal force is a new type of force exerted on an object.

TIP When you derive a new mathematical relation for physical quantities, it is always useful to examine how reasonable it is in limiting cases.



EXAMPLE 5.2 **Pilot blackout**

When a pilot pulls out from the bottom of a dive, his body moves at high speed along a segment of an upward-bending approximately circular path. However, while his body moves up, his blood tends to move straight ahead (tangent to the circle) and begins to fill the easily expandable veins in his legs. This can deprive his brain of blood and cause a blackout if the radial acceleration is $4g$ or more and lasts several seconds. Suppose during a dive an airplane moves at a modest speed of $v = 80$ m/s (180 mi/h) through a circular arc of radius $r = 150$ m. Is the pilot likely to black out?

Sketch and translate We sketch the situation. To determine if blackout occurs, we estimate the radial acceleration of the pilot as he passes along the lowest point of the circular path.

Simplify and diagram Assume that at the bottom of the plane's dive, the plane is moving in a circle at constant speed and the point of interest is the lowest point on the circle. Assume also that the magnitude of the plane's acceleration is constant for a quarter circle, that is, one-eighth of a circle on each side of the bottom point. The acceleration points up (see the velocity change method shown below).

Represent mathematically We calculate the magnitude of the radial acceleration using Eq. (5.3):

$$a_r = \frac{v^2}{r}$$

To estimate the time interval that the pilot will experience this acceleration, we calculate the time interval for the plane to move through the part of the dive represented by a quarter circle (arc length $l = 2\pi r/4$):

$$\Delta t = \frac{l}{v} = \frac{2\pi r/4}{v}$$

Solve and evaluate Inserting the given quantities, we find:

$$a_r = \frac{(80\ \text{m/s})^2}{150\ \text{m}} = 43\ \text{m/s}^2$$

The acceleration is more than four times greater than g (more than $4 \times 9.8\ \text{m/s}^2$). Thus, the pilot could potentially black out if the acceleration lasts too long. The time interval during which the pilot will experience this acceleration is about

$$\Delta t = \frac{[\,2\pi(150\ \text{m})\,]/4}{80\ \text{m/s}} = \frac{240\ \text{m}}{80\ \text{m/s}} \approx 3\ \text{s}$$

This is long enough that blackout is definitely a concern. Special flight suits, however, exert considerable pressure on the legs during such motion. This pressure stops blood from accumulating in the veins of the legs and thus prevents a pilot blackout.

Try it yourself Imagine that you are a passenger on a roller coaster with a double loop-the-loop—two consecutive loops. You are traveling at speed 24 m/s as you move along the bottom part of a loop of radius 10 m. Determine (a) the magnitude of your radial acceleration while passing the lowest point of that loop and (b) the time interval needed to travel along the bottom quarter of that approximately circular loop. (c) Are you at risk of blacking out? Explain.

Answer (a) 58 m/s^2, or almost six times the 9.8 m/s^2 free-fall acceleration; (b) about 0.7 s; (c) the acceleration is more than enough to cause blackout but does not last long enough, so you are safe from blacking out and will get a good thrill!

Period

TIP Do not confuse the symbol T for period with the symbol T for the tension force that a string exerts on an object.

When an object repeatedly moves in a circle, we can describe its motion with another useful physical quantity, its **period** T. The period equals the time interval that it takes an object to travel around the entire circular path one time and has the units of time. For example, suppose that a bicyclist racing on a circular track takes 24 s to complete a circle that is 400 m in circumference. The period T of the motion is 24 s.

For constant speed circular motion we can determine the speed of an object by dividing the distance traveled in one period (the circumference of the circular path, $2\pi r$) by the time interval T it took the object to travel that distance (its period), or $v = 2\pi r/T$. Thus,

$$T = \frac{2\pi r}{v} \tag{5.4}$$

We can express the radial acceleration of the object in terms of its period by inserting this expression for speed in terms of period $v = 2\pi r/T$ into Eq. (5.3):

$$a_r = \frac{v^2}{r} = \left(\frac{2\pi r}{T}\right)^2 \frac{1}{r} = \frac{4\pi^2 r^2}{T^2 r} = \frac{4\pi^2 r}{T^2} \tag{5.5}$$

Let's use limiting case analysis to see if Eq. (5.5) is reasonable. If the speed of the object is extremely large, its period would be very short ($T = 2\pi r/v$). Thus, according to Eq. (5.5), its radial acceleration would be very large. That makes sense—high speed and large radial acceleration. Similarly, if the speed of the object is small, its period will be very large and its radial acceleration will be small. That also makes sense.

We can use Eq. (5.5) to calculate our acceleration on the surface of Earth due to Earth's rotation around its axis. Imagine we are interested in calculating radial acceleration in Singapore, which is on the equator, with $r = 6400$ km and $T = 24$ h. Making the appropriate unit conversions, we find the magnitude of the acceleration:

$$a_r = \frac{4\pi^2(6.4 \times 10^6 \text{m})}{(24 \text{ h} \times 3600 \text{ s/h})^2} = 0.034 \text{ m/s}^2$$

This is a very small number compared to the much greater free-fall acceleration of objects near Earth's surface—9.8 m/s^2. Because it is so small, the radial acceleration due to Earth's rotation around its axis can be ignored under most circumstances.

Remember that Newton's laws were formulated and are valid only for observers in inertial reference frames, that is, for observers who are not accelerating. But we have just discovered that observers on Earth's surface are accelerating due to Earth's rotation. Does this mean that Newton's laws do not apply? As we found above, the acceleration due to Earth's rotation is much smaller than the accelerations we experience from other types of motion. Thus, in most situations we can assume that Earth is not rotating and therefore *does* count as an inertial reference frame, and we can apply Newton's laws on Earth.

REVIEW QUESTION 5.3 Show that the two expressions for radial acceleration (v^2/r and $4\pi^2 r/T^2$) have the correct units of acceleration.

5.4 Skills for analyzing processes involving circular motion

The strategy for analyzing processes involving constant speed circular motion is similar to that used to analyze linear motion processes. However, when we analyze constant speed circular motion processes, we do *not* use traditional x- and y-axes but instead use a radial r-axis and sometimes a vertical y-axis. **The radial *r*-axis should always point *toward the center of the circle***. The radial acceleration of magnitude $a_r = v^2/r$ is positive along this axis. The application of Newton's second law for circular motion using a radial axis is summarized below.

Circular motion component form of Newton's second law For the radial direction (the axis pointing toward the center of the circular path), the component form of Newton's second law is

$$a_r = \frac{\Sigma F_r}{m} \quad \text{or} \quad ma_r = \Sigma F_r \tag{5.6}$$

where ΣF_r is the sum of the radial components of all forces exerted on the object moving in the circle (positive toward the center of the circle and negative away from the center), and $a_r = v^2/r$ is the magnitude of the radial acceleration of the object.

(CONTINUED)

For some situations, usually when friction forces are involved (for example, a car moving around a highway curve or a person standing on the platform of a merry-go-round), we also include in the analysis the force components along a perpendicular vertical y-axis:

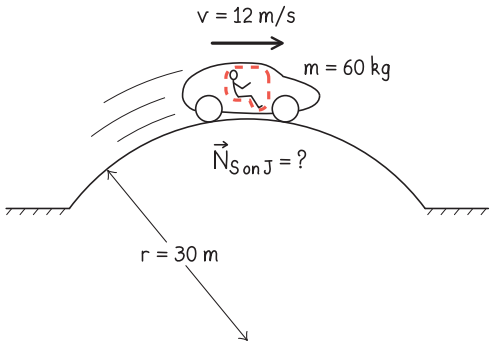
$$ma_y = \Sigma F_y = 0 \tag{5.7}$$

When an object moves with uniform (constant speed) circular motion, both the y-component of its acceleration and the y-component of the sum of the forces exerted on it are zero.

PROBLEM-SOLVING STRATEGY 5.1 Processes involving constant speed circular motion

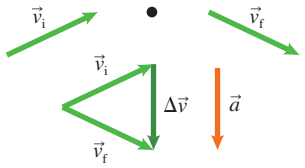
Sketch and translate

- Sketch the situation described in the problem statement. Label it with all relevant information.
- Choose the system and a specific position to analyze its motion.
- Identify the unknown that you need to find and label it with a question mark.



Simplify and diagram

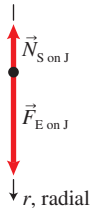
- Decide if the system can be modeled as a point-like object.
- Determine if the constant speed circular motion approach is appropriate.
- Indicate with an arrow the direction of the object's acceleration as it passes the chosen position.
- Draw a force diagram for the system at the instant it passes that position.
- On the force diagram, draw an axis in the radial direction toward the center of the circle.



EXAMPLE 5.3 Driving over a hump in the road

Josh drives his car at a constant 12 m/s speed over a bridge whose shape is bowed in the vertical arc of a circle. Find the direction and the magnitude of the force exerted by the car seat on Josh as he passes the top of the 30-m-radius arc. His mass is 60 kg.

The sketch includes all of the relevant information: Josh's speed, his mass, and the radius of the arc along which the car moves. Josh is the system.



Consider Josh a point-like object and analyze him as he passes the highest part of the vertical circle along which he travels.

A velocity change diagram as he passes the top of the circular path indicates that he has a downward radial acceleration toward the center of the circle.

The forces exerted on him are shown in the force diagram. The sum of the forces must also point down. Thus, the upward normal force $\vec{N}_{S\text{ on }J}$ that the car seat exerts on Josh is smaller in magnitude than the downward gravitational force $\vec{F}_{E\text{ on }J}$ that Earth exerts on Josh. A radial r-axis points down toward the center of the circle.

Represent mathematically

- Convert the force diagram into the radial r-component form of Newton's second law.
- For objects moving in a horizontal circle (unlike this example), you may also need to apply a vertical y-component form of Newton's second law.

Solve and evaluate

- Solve the equations formulated in the previous two steps.
- Evaluate the results to see if they are reasonable (the magnitude of the answer, its units, limiting cases).

Apply the radial form of Newton's second law $ma_r = \Sigma F_r$.

The radial components of the two forces exerted on Josh are $F_{\text{E on J}\,r} = +F_{\text{E on J}} = +mg$ and $N_{\text{S on J}\,r} = -N_{\text{S on J}}$. The magnitude of the radial acceleration is $a_r = v^2/r$. Therefore, the radial form of Newton's second law is

$$m\frac{v^2}{r} = +mg + (-N_{\text{S on J}})$$

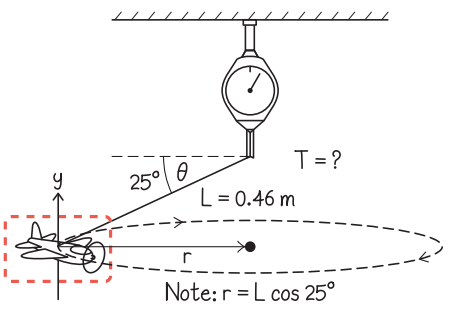
Solving for $N_{\text{S on J}}$, we have

$$N_{\text{S on J}} = mg - m\frac{v^2}{r}$$

Substituting the known information into the previous equation, we get

$$N_{\text{S on J}} = (60\text{ kg})(9.8\text{ m/s}^2) - (60\text{ kg})\frac{(12\text{ m/s})^2}{(30\text{ m})} = 588\text{ N} - 288\text{ N} = 300\text{ N}$$

The seat exerts a smaller upward force on Josh than Earth pulls down on him. You have probably noticed this effect when going over a smooth hump in a roller coaster or while in a car or on a bicycle when crossing a hump in the road—it almost feels like you are leaving the seat or starting to float briefly above it. This feeling is caused by the reduced upward normal force that the seat exerts on you.

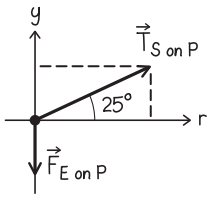


Try it yourself Imagine that Josh drives on a road that has a dip in it. The speed of the car and the radius of the dip are the same as in Example 5.3. Find the direction and the magnitude of the force exerted by the car seat on Josh as he passes the bottom of the 30-m-radius dip.

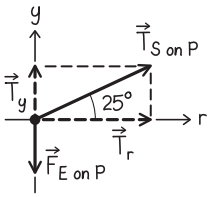
Answer The seat exerts an upward force of 880 N. This is almost 50% more than the 590-N force that Earth exerts on Josh—he sinks into the seat.

The next three examples involve processes in which some of the forces have nonzero radial r-components *and* some of the forces have nonzero vertical y-components. To solve these problems we will use the component form of Newton's second law in both the radial r- and vertical y-directions.

EXAMPLE 5.4 Toy airplane



You have probably seen toy airplanes flying in a circle at the end of a string. Once the plane reaches a constant speed, it does not move up or down, just around in a horizontal circle. Suppose you have an airplane attached to the end of a 46-cm string, which makes a 25° angle relative to the horizontal while the airplane is flying. A scale at the top of the string measures the force that the string exerts on the airplane. Find the period of the airplane's motion (the time interval for it to complete one circle).



Sketch and translate We sketch the situation, including the known information: the length of the string and the angle of the string relative to the horizontal. The airplane is the system.

(CONTINUED)

Simplify and diagram Neglect the airplane's interaction with the air and assume that it is a point-like object moving at constant speed in a horizontal circle. To draw a force diagram, identify objects that interact with the airplane—in this case, Earth and the string. Include a vertical y-axis and a radial r-axis; note that the radial axis points horizontally toward the center of the circle—not along the string. Because the airplane moves at constant speed, its acceleration points toward the center of the circle—it has a radial component but does not have a vertical component. Thus, the vertical component of the tension force that the string exerts on the plane $\vec{T}_{\text{S on P}\,y}$ must balance the downward force that Earth exerts on the plane $\vec{F}_{\text{E on P}}$, which has magnitude $m_{\text{P}}g$ (see the force diagram broken into components at right). The radial component of the force that the string exerts on the plane is the only force with a nonzero radial component and causes the plane's radial acceleration.

Represent mathematically We use the force diagram to help apply Newton's second law in component form. First, apply the vertical y-component form of Newton's second law: $m_{\text{P}}a_y = \Sigma F_y$. The y-components of the forces exerted on the plane are $T_{\text{S on P}\,y} = +T_{\text{S on P}} \sin 25°$ and $F_{\text{E on P}\,y} = -m_{\text{P}}g$, and the y-component of the plane's acceleration is zero. We can now apply the y-component form of Newton's second law:

$$0 = +T_{\text{S on P}} \sin 25° + (-m_{\text{P}}g)$$

Next, apply the radial r-component version of Newton's second law: $m_{\text{P}}a_r = \Sigma F_r$. The force exerted by Earth on the plane does not have a radial component. The radial component of the force exerted by the string on the plane is $T_{\text{S on P}\,r} = +T_{\text{S on P}} \cos 25°$, and the magnitude of the radial acceleration is $a_r = 4\pi^2 r/T^2$, where T is the period of the plane's motion [Eq. (5.5)]. Thus:

$$m_{\text{P}}\frac{4\pi^2 r}{T^2} = +T_{\text{S on P}} \cos 25°$$

Note that $T_{\text{S on P}}$ represents the magnitude of the tension force that the string exerts on the airplane and T represents the period of the plane's motion—the time interval it takes the plane to travel once around its circular path. Note that the radius of the circular path is not the length of the string but is instead

$$r = L \cos 25° = (0.46\text{ m})\cos 25° = 0.417\text{ m}$$

where L is the length of the string (46 cm).

Solve and evaluate The goal is to find the period T of the plane's circular motion. Unfortunately, the above radial application of Newton's second law has three unknowns: $T_{\text{S on P}}$, T, and the mass of the plane. However, we can rearrange the vertical y-equation to get an expression for the magnitude of the tension force exerted by the string on the plane:

$$T_{\text{S on P}} = \frac{m_{\text{P}}g}{\sin 25°}$$

Insert this expression for $T_{\text{S on P}}$ into the radial component equation to get an expression that does *not* involve the force that the string exerts on the plane:

$$m_{\text{P}}\frac{4\pi^2 r}{T^2} = \frac{m_{\text{P}}g}{\sin 25°}\cos 25°$$

Divide both sides by m_{P}, multiply both sides by T^2, and do some rearranging to get

$$T^2 = \frac{4\pi^2 r \sin 25°}{g \cos 25°}$$

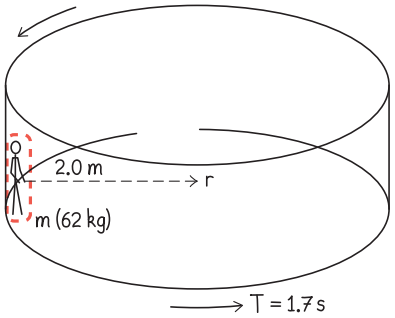
Taking the square root of each side, we find that

$$T = 2\pi\sqrt{\frac{r \sin 25°}{g \cos 25°}}$$

Substituting the known information, we calculate the period to be

$$T = 2\pi\sqrt{\frac{(0.417\text{ m})\sin 25°}{(9.8\text{ m/s}^2)\cos 25°}} = 0.88\text{ s}$$

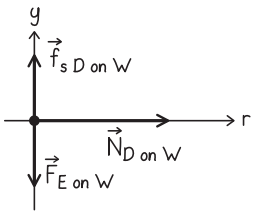
Try it yourself Imagine that another plane of mass 0.12 kg moves with a speed of 6.2 m/s. A spring scale measures the tension force that the string exerts on the plane as 5.0 N. Find the radius of the plane's orbit.



Answer 0.95 m.

Many carnivals and amusement parks have a "rotor ride" in which people stand up against the wall of a spinning circular room. The room (also called the "drum") spins faster until, at a certain speed, the floor drops out! Amazingly, the people remain up against the wall with their feet dangling. How is this possible?

EXAMPLE 5.5 Rotor ride



A 62-kg woman is a passenger in a rotor ride. A drum of radius 2.0 m rotates faster and faster about a vertical axis until it reaches a period of 1.7 s. When the drum reaches this turning rate, the floor drops away, but the woman does not slide down the wall of the drum. Which characteristics of the ride ensure that the woman remains stuck to the wall? Justify your answer quantitatively.

Sketch and translate Representing the situation in different ways should help us decide which characteristics of the drum are important. We start with a sketch with all the relevant information. The woman is the system. Her mass is $m_{\text{W}} = 62$ kg, the radius of her circular path is $r = 2.0$ m, and the period of her circular motion is $T = 1.7$ s.

Simplify and diagram Model the woman as a point-like object and consider the situation once the drum has reached its maximum (constant) speed. Because she is moving in a circular path at constant speed, her acceleration points toward the center of the circle, and we can use our understanding of constant speed circular motion to analyze the situation.

Next, draw a force diagram for the woman as she passes one point along the circular path. She interacts with two objects—Earth and the drum. Earth exerts a downward gravitational force $\vec{F}_{\text{E on W}}$ on her. The drum exerts a force that we can resolve into two vector components: a normal force $\vec{N}_{\text{D on W}}$ perpendicular to the drum's surface and toward the center of the circle and an upward static friction force $\vec{f}_{\text{s D on W}}$ parallel to its surface. Include a radial r-axis that points toward the center of the drum and a vertical y-axis pointing upward. Examining the force diagram, we see that if the maximum upward static friction force is less than the downward gravitational force, the woman will slip. Thus the question can be formulated as follows: how large must the coefficient of static friction be so that the static friction force exerted on the woman by the drum balances the force that Earth exerts on her?

Represent mathematically Use the force diagram to help apply the component form of Newton's second law for the inward radial r-direction and for the vertical y-direction. The normal force is the only force that has a nonzero radial component.

Radial r-equation: $$m_{\text{W}}a_r = \Sigma F_r$$

$$\Rightarrow m_{\text{W}}\frac{v^2}{r} = N_{\text{D on W}}$$

Now, consider the y-component form of Newton's second law. The static friction force $\vec{f}_{\text{s D on W}}$ points in the positive y-direction, and the gravitational force $\vec{F}_{\text{E on W}}$ points in the negative y-direction. Since these forces must balance for the woman not to slip, the y-component of the woman's acceleration should be zero.

Vertical y-equation: $$m_{\text{W}}a_y = \Sigma F_y$$

$$\Rightarrow 0 = f_{\text{s D on W}} + (-F_{\text{E on W}})$$

Assume that the static friction force is at its maximum possible value, meaning $f_{\text{s D on W}} = \mu_{\text{s}}N_{\text{D on W}}$. We wish to find the smallest (minimum) coefficient of static friction $\mu_{\text{s min}}$ that results in the woman remaining stationary. Substitute this minimum coefficient of static friction and the earlier expression for the normal force exerted by the drum into this expression:

$$f_{\text{s max D on W}} = \mu_{\text{s min}}N_{\text{D on W}} = \mu_{\text{s min}}m_{\text{W}}\frac{v^2}{r}$$

Substituting this expression for $f_{\text{s max D on W}}$ and $F_{\text{E on W}} = m_{\text{W}}g$ into the vertical y-component application of Newton's second law, we get

$$0 = \mu_{\text{s min}}m_{\text{W}}\frac{v^2}{r} - m_{\text{W}}g$$

Notice that the woman's mass cancels out of this equation. This means that the rotor ride works equally well for any person, independent of the person's mass, and for many people at once as well!

To determine the minimum value of μ_{s} needed to prevent the woman from sliding, we divide both sides by $m_{\text{W}}v^2$, multiply by r, and rearrange to get

$$\mu_{\text{s min}} = \frac{gr}{v^2}$$

We find the woman's speed by using the information we have about the radius and period of her circular motion:

$$v = \frac{2\pi r}{T}$$

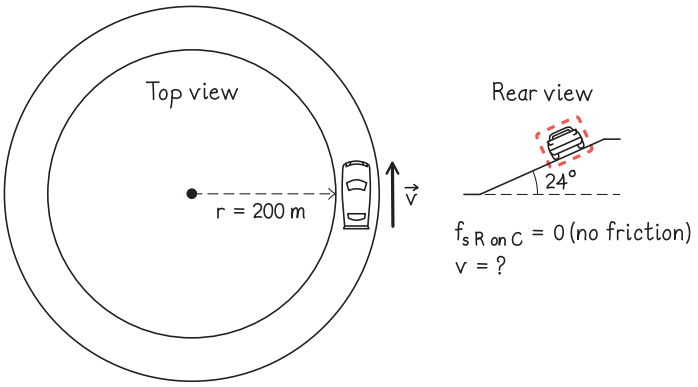
Plug this expression for the speed into the equation above for the minimum coefficient of friction:

$$\mu_{\text{s min}} = \frac{gr}{v^2} = \frac{grT^2}{4\pi^2r^2} = \frac{gT^2}{4\pi^2r}$$

Solve and evaluate We can now use the given information to find the minimum coefficient of friction:

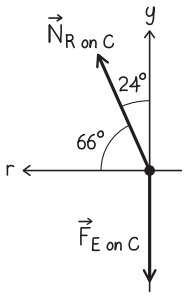
$$\mu_{\text{s min}} = \frac{gT^2}{4\pi^2r} = \frac{9.8\ \text{m/s}^2 \times (1.7\ \text{s})^2}{4 \times 9.87 \times 2.0\ \text{m}} = 0.36$$

The coefficient of friction is a number with no units (also called *dimensionless*), and our answer also has no units. The magnitude 0.36 is reasonable and easy to obtain with everyday materials (wood on wood ranges from 0.25 to 0.5). To be on the safe side, we probably want to make the surface rougher, with twice the minimum coefficient of static friction. The limiting case analysis of the final expression also supports the result. If the drum is stationary ($T = \infty$), the coefficient of static friction would have to be infinite—the person would have to be glued permanently to the vertical surface. Perhaps most important, the required coefficient of static friction does not depend on the mass of the rider. Earth exerts a greater gravitational force on a more massive person. But the drum also pushes toward the center with a greater normal force, which leads to an increased friction force. The effects balance, and the mass does not matter.



Try it yourself Merry-go-rounds have railings for people to hold when riding. What is the purpose of the railings? Answer this question by drawing a force diagram for an adult standing on a rotating merry-go-round.

Answer The railings exert a force on the person in the radial direction. This force helps provide the necessary radial acceleration.



EXAMPLE 5.6 Texas Motor Speedway

The Texas Motor Speedway is a 2.4-km (1.5-mile)-long oval track. One of its turns is about 200 m in radius and is banked at 24° above the horizontal. How fast would a car have to move so that no friction is needed to prevent it from sliding sideways off the raceway (into the infield or off the track)?

Sketch and translate We start by drawing top view and rear view sketches of the situation. The car is the system. For simplicity, we draw the speedway as a circular track.

Simplify and diagram Model the car as a point-like object that moves along a circular path at constant speed. Earth exerts a downward force $\vec{F}_{E\,on\,C}$. The surface of the road R exerts on the car a normal force $\vec{N}_{R\,on\,C}$ perpendicular to the surface (see the force diagram at right). We assume the sideways friction force exerted by the road on the car is zero (see the problem statement). For constant speed circular motion, the sum of the forces exerted on the car should point toward the center of the circle. The horizontal radial component of the normal force $N_{R\,on\,C\,r}$ causes the radial acceleration toward the center. Since the vertical y-component of the car's acceleration is zero, the vertical y-component of the normal force $N_{R\,on\,C\,y}$ balances the downward gravitational force $\vec{F}_{E\,on\,C}$ that Earth exerts on the car.

Represent mathematically Use the force diagram to help apply the radial r- and vertical y-component forms of Newton's second law. Let's start with the vertical y-equation.

Vertical y-equation: $m_C a_y = \Sigma F_y = N_{R\,on\,C\,y} + F_{E\,on\,C\,y}$

Since $a_y = 0$, $N_{R\,on\,C\,y} = N_{R\,on\,C} \sin 66°$, and $F_{E\,on\,C\,y} = -m_C g$, we get $0 = +N_{R\,on\,C} \sin 66° - m_C g$, or

$$N_{R\,on\,C} \sin 66° = m_C g \tag{5.8}$$

Now, apply the radial component equation.

Radial r-equation: $m_C a_r = \Sigma F_r = N_{R\,on\,C\,r} + F_{E\,on\,C\,r}$

Since $a_r = v^2/r$, $N_{R\,on\,C\,r} = N_{R\,on\,C} \cos 66°$, and $F_{E\,on\,C\,r} = 0$, we get:

$$m_C \frac{v^2}{r} = N_{R\,on\,C} \cos 66° + 0 \tag{5.9}$$

Now combine Eqs. (5.8) and (5.9) to eliminate $N_{R\,on\,C}$ and determine an expression for the speed of the car. To do this, divide the first equation by the second with the $N_{R\,on\,C}$ sides of each equation on the left:

$$\frac{N_{R\,on\,C} \sin 66°}{N_{R\,on\,C} \cos 66°} = \frac{m_C g}{m_C \frac{v^2}{r}}$$

Canceling $N_{R\,on\,C}$ on the left side and the m_C on the right side and remembering that

$$\frac{\sin 66°}{\cos 66°} = \tan 66°$$

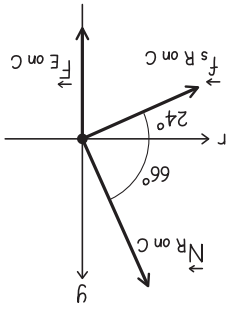
we get

$$\tan 66° = \frac{gr}{v^2}$$

Rearrange the above to find v^2:

$$v^2 = \frac{gr}{\tan 66°}$$

Solve and evaluate The road has a radius $r = 200$ m. Thus,



$$v = \sqrt{\frac{gr}{\tan 66°}} = \sqrt{\frac{(9.8\ \text{m/s}^2)(200\ \text{m})}{\tan 66°}}$$

$$= 29.5\ \text{m/s} \approx 30\ \text{m/s} = 66\ \text{mi/h}$$

This is clearly much slower than the speed of actual racecars. See the "Try it yourself" question.

Try it yourself Construct a force diagram for a racecar that is traveling somewhat faster around the circular track and indicate what keeps the racecar moving in a circle at this higher speed.

Answer If the racecar is going faster than 30 m/s, static friction has to push in on the car parallel to the road surface and toward the center of the track, as shown. The friction force has a negative y-component and causes the normal force to be bigger. The combination of the radial components of the increased magnitude normal force and the static friction force provides the much greater net radial force needed to keep the car moving in a circle.

TIP Remember that there is no special force that causes the radial acceleration of an object moving at constant speed along a circular path. This acceleration is caused by all of the forces exerted on the system by other objects (Earth, the surface of a road, a rope. . .). Add the radial components of these regular forces. This sum is what causes the radial acceleration of the system.

Conceptual difficulties with circular motion

Although Newton's second law applies to circular motion just as it applies to linear motion, some everyday experiences seem to contradict that fact. Imagine that you sit on the left side of the back seat of a taxi moving at high speed on a straight road. After traveling straight for a while, the taxi starts to make a high speed *left* turn (**Figure 5.2**). The car seat is slippery and you aren't holding on to anything. As the car turns left, you start sliding across the seat *toward the right* with respect to the car until you hit the door on the other side of the car. This feeling of being thrown outward in a turning car seems inconsistent with the idea that sum of the forces (the net) points toward the center of the circle during circular motion. The feeling that there is a force pushing outward on you seems very real, but what object is exerting that force?

Remember that Newton's laws explain motion only when made by an observer in an inertial reference frame. Since the car is accelerating as it goes around the curve, it is not an inertial reference frame. To a roadside observer, you and the car were moving at constant velocity before the car started turning. The forces exerted on you by Earth and the car seat added to zero. The observer saw the car begin turning to the left and you continuing to travel with constant velocity because the sum of the forces that other objects exerted on you was zero (we assume that the seat is slippery and the friction force that the surface of the seat exerted on you was very small). When the door finally intercepted your forward-moving body, it started exerting a force on you toward the center of the circle. At that moment, you started moving with the car at constant speed but changing velocity along the circular path. Your velocity then changed because of the force exerted on you by the door.

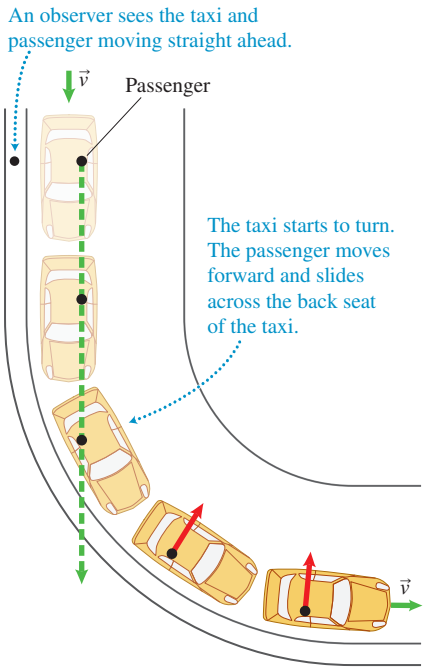


FIGURE 5.2 An observer's view of a passenger as a taxi makes a high-speed turn.

REVIEW QUESTION 5.4 Think back to Example 5.5 (the rotor ride). Use your understanding of Newton's laws and constant speed circular motion to explain why the woman in the ride seems to feel a strong force pushing her against the wall of the drum.

5.5 The law of universal gravitation

So far, we have investigated examples of circular motion on or near the surface of Earth. Now let's look at circular motion as it occurs for planets moving around the Sun and for satellites and our Moon moving around Earth.

Observations and explanations of planetary motion

By Newton's time, scientists already knew a great deal about the motion of the planets in the solar system. Planets were known to move around the Sun at approximately constant speed in almost circular orbits. (Actually, the orbits have a slightly elliptical shape.) However, no one had a scientific explanation for what was causing the Moon and the planets to travel in their nearly circular orbits.

Newton was among the first to hypothesize that the Moon moved in a circular orbit around Earth because Earth pulled on it, continuously changing the direction of the Moon's velocity. He wondered if the force exerted by Earth on the Moon was the same type of force as the force that Earth exerted on falling objects, such as an apple falling from a tree.

The dependence of gravitational force on distance Newton realized that directly measuring the gravitational force exerted by Earth on a distant object was impossible. However, his second law ($\vec{a} = \Sigma\vec{F}/m$) provided an indirect way to determine the gravitational force exerted by Earth: measure the acceleration of the object and use the

second law to determine the gravitational force. He knew that the Moon was separated from Earth by about $r_M = 3.8 \times 10^8$ m, roughly 60 Earth radii $(60R_E)$. With this distance and the Moon's orbital period of 27.3 days, Newton was able to use Eq. (5.5) to determine the Moon's radial acceleration:

$$a_{r \text{ at } R=60R_E} = \frac{4\pi^2 R}{T^2} = \frac{4\pi^2(3.8 \times 10^8 \text{ m})}{[\,(27.3 \text{ days})(86{,}400 \text{ s/day})\,]^2}$$
$$= \frac{4\pi^2(3.8 \times 10^8 \text{ m})}{(2.36 \times 10^6 \text{ s})^2} = 2.69 \times 10^{-3} \text{ m/s}^2$$

He then did a similar analysis for a second situation. He performed a thought experiment in which he imagined what would happen if the Moon were condensed to a small point-like object (while keeping its mass the same) located near Earth's surface. This would place the "Moon particle" at a distance of one Earth radius $(1\,R_E)$ from Earth's center. If the Moon only interacted with Earth, it would have the same free-fall acceleration as any object near Earth's surface (9.8 m/s^2), since this acceleration is independent of mass. Now Newton knew the Moon's acceleration at two different distances from Earth's center.

Newton then used this information to determine how the gravitational force that one object exerts on another depends on the separation of the objects, assuming that the force causing the acceleration of the Moon is the gravitational force exerted on it by Earth and that this force changes with the separation of the objects. He took the ratio of these two accelerations using his second law:

$$\frac{a_{r \text{ at } R=60R_E}}{a_{r \text{ at } R=1R_E}} = \frac{F_{\text{E on Moon at } R=60R_E}/m_{\text{Moon}}}{F_{\text{E on Moon at } R=1R_E}/m_{\text{Moon}}} = \frac{F_{\text{E on Moon at } R=60R_E}}{F_{\text{E on Moon at } R=1R_E}}$$

Notice that the Moon's mass cancels when taking this ratio. Substituting the two accelerations he had observed, Newton made the following comparison between the forces:

$$\frac{F_{\text{E on Moon at } R=60R_E}}{F_{\text{E on Moon at } R=1R_E}} = \frac{a_{r \text{ at } R=60R_E}}{a_{r \text{ at } R=1R_E}} = \frac{2.69 \times 10^{-3} \text{ m/s}^2}{9.8 \text{ m/s}^2} = \frac{1}{3600} = \frac{1}{60^2}$$

$$\Rightarrow F_{\text{E on Moon at } R=60R_E} = \frac{1}{60^2} F_{\text{E on Moon at } R=1R_E}$$

TIP You might be wondering why if Earth pulls on the Moon, the Moon does not come closer to Earth in the same way that an apple falls from a tree. The difference in these two cases is the speed of the objects. The apple is at rest with respect to Earth before it leaves the tree, and the Moon is moving tangentially. Think of what would happen to the Moon if Earth stopped pulling on it—it would fly away along a straight line.

The force exerted on the Moon when the Moon is at a distance of 60 times Earth's radius is $1/60^2$ times the force exerted on the Moon when near Earth's surface (about 1 times Earth's radius). It appears that as the distance from Earth's center to the Moon *increases* by a factor of 60, the force decreases by a factor of $1/60^2 = 1/3600$. This suggests that the gravitational force that Earth exerts on the Moon depends on the inverse square of its distance from the center of Earth:

$$F_{\text{E on Moon at } r} \propto \frac{1}{r^2} \tag{5.10}$$

The dependence of gravitational force on mass Newton next wanted to determine in what way the gravitational force depended on the masses of the interacting objects. Remember that the free-fall acceleration of an object near Earth's surface does not depend on the object's mass. All objects have the same free-fall acceleration of 9.8 m/s^2:

$$a_O = \frac{F_{\text{E on O}}}{m_O} = g$$

Mathematically, this only works if the magnitude of the gravitational force that Earth exerts on a falling object $F_{\text{E on O}}$ is proportional to the mass of that object: $F_{\text{E on O}} = m_O g$. Newton assumed that the gravitational force that Earth exerts on the Moon has this same feature—the gravitational force must be proportional to the Moon's mass:

$$F_{\text{E on M}} \propto m_{\text{Moon}} \tag{5.11}$$

The last question was to decide whether the gravitational force exerted by Earth on the Moon depends only on the Moon's mass or on the mass of Earth as well. Newton's own

third law suggested an answer. If Earth exerts a gravitational force on the Moon, then according to Newton's third law the Moon must also exert a gravitational force on Earth that is equal in magnitude (see **Figure 5.3**). Because of this, Newton decided that the gravitational force exerted by Earth on the Moon should also be proportional to the mass of Earth:

$$F_{\text{E on M}} = F_{\text{M on E}} \propto m_{\text{Earth}} \tag{5.12}$$

Newton then combined Eqs. (5.10)–(5.12), obtaining a mathematical relationship for the dependence of the gravitational force on all these factors:

$$F_{\text{E on M}} = F_{\text{M on E}} \propto \frac{m_{\text{Earth}} m_{\text{Moon}}}{r^2} \tag{5.13}$$

Newton further proposed that this was not just a mathematical description of the gravitational interaction between Earth and the Moon, but that it was more general and described the gravitational interaction between any two objects; he called this relation the **law of universal gravitation**. Newton's extension of the applicability of Eq. (5.13) to celestial objects was based on his analysis of Kepler's laws, which you will read about in the next section.

When Newton devised Eq. (5.13), he did not know the masses of Earth and the Moon and could not measure the force that one exerted on the other. Thus, the best he could do was to construct the above proportionality relationship. It was much later that scientists determined the value of the constant of proportionality:

$$G = 6.67 \times 10^{-11}\ \text{N} \cdot \text{m}^2/\text{kg}^2$$

G, known as the **gravitational constant**, allows us to write a complete mathematical equation for the gravitational force that one mass exerts on another:

$$F_{g\ 1\text{ on }2} = G\frac{m_1 m_2}{r^2} \tag{5.14}$$

Notice that the value of the gravitational constant is quite small. If you take two objects, each with a mass of 1.0 kg, and separate them by 1.0 m, the force that they exert on each other equals 6.67×10^{-11} N. This means that the gravitational force that objects like us (with masses of about 50–100 kg) exert on each other is extremely weak. However, because the masses of celestial objects are huge (Earth's mass is approximately 6.0×10^{24} kg and the Sun's mass is 2.0×10^{30} kg), the gravitational forces that they exert on each other are very large, despite the small value of the gravitational constant.

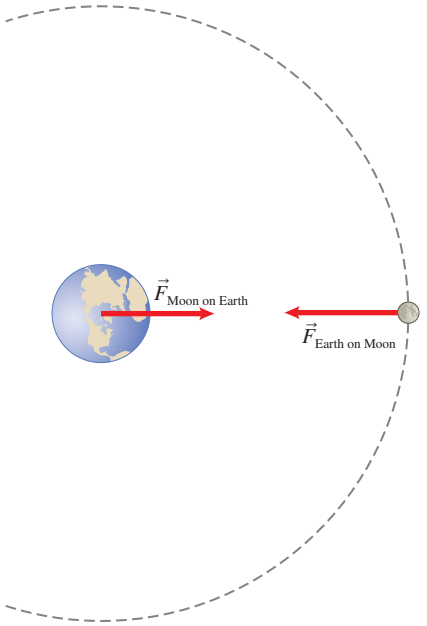

FIGURE 5.3 Earth and the Moon exert equal–magnitude and oppositely directed forces on each other. (Earth and Moon not drawn to scale.)

Newton's third law and the gravitational force

The mass of Earth is approximately 6.0×10^{24} kg. The mass of a tennis ball is approximately 50 g, or 5.0×10^{-2} kg. How does the gravitational force that Earth exerts downward on the ball compare to the upward force that the ball exerts on Earth? According to Newton's third law, interacting objects exert forces of equal magnitude and opposite direction on each other. The gravitational force exerted by Earth on the ball has the same magnitude as the force that the ball exerts on Earth. Equation (5.14) is consistent with this idea:

$$F_{\text{E on B}} = G\frac{M_{\text{E}} m_{\text{B}}}{r^2}$$

$$= (6.67 \times 10^{-11}\ \text{N} \cdot \text{m}^2/\text{kg}^2)\frac{(6.0 \times 10^{24}\ \text{kg})(5.0 \times 10^{-2}\ \text{kg})}{(6.4 \times 10^{6}\ \text{m})^2} = 0.49\ \text{N}$$

$$F_{\text{B on E}} = G\frac{m_{\text{B}} M_{\text{E}}}{r^2}$$

$$= (6.67 \times 10^{-11}\ \text{N} \cdot \text{m}^2/\text{kg}^2)\frac{(5.0 \times 10^{-2}\ \text{kg})(6.0 \times 10^{24}\ \text{kg})}{(6.4 \times 10^{6}\ \text{m})^2} = 0.49\ \text{N}$$

(In the denominator we use the distance between the center of Earth and the center of the ball.)

It might seem counterintuitive that the ball exerts a gravitational force on Earth. After all, Earth doesn't seem to react every time someone drops something. But according to Newton's second law, if the ball exerts a nonzero net force on Earth, then Earth should accelerate. What is the magnitude of this acceleration?

$$a_{\mathrm{E}} = \frac{F_{\mathrm{B\ on\ E}}}{M_{\mathrm{E}}} = \frac{0.49\ \mathrm{N}}{6.0 \times 10^{24}\ \mathrm{kg}} = 8.2 \times 10^{-26}\ \mathrm{m/s^2}$$

Earth's acceleration is so tiny that there is no known way to observe it. On the other hand, the acceleration of the ball is easily noticeable since the ball's mass is so much smaller.

$$a_{\mathrm{B}} = \frac{F_{\mathrm{E\ on\ B}}}{m_{\mathrm{B}}} = \frac{0.49\ \mathrm{N}}{(5.0 \times 10^{-2}\ \mathrm{kg})} = 9.8\ \mathrm{m/s^2}$$

Notice that the ball has the familiar free-fall acceleration. In fact, the discussion above allows us to understand why free-fall acceleration on Earth equals $9.8\,\mathrm{m/s^2}$ and not some other number. Use Newton's second law and the law of gravitation for an object falling freely near Earth's surface to determine its acceleration:

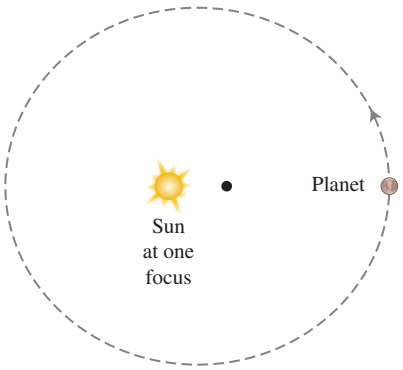
$$a_{\mathrm{object}} = \frac{F_{\mathrm{Earth\ on\ object}}}{m_{\mathrm{object}}} = \frac{(GM_{\mathrm{Earth}}m_{\mathrm{object}})/R_{\mathrm{Earth}}^2}{m_{\mathrm{object}}} = \frac{GM_{\mathrm{Earth}}}{R_{\mathrm{Earth}}^2}$$

Inserting Earth's mass $M_{\mathrm{Earth}} = 5.97 \times 10^{24}\,\mathrm{kg}$ and its radius $R_{\mathrm{Earth}} = 6.37 \times 10^{6}\,\mathrm{m}$, we have

$$a_{\mathrm{object}} = \frac{GM_{\mathrm{Earth}}}{R_{\mathrm{Earth}}^2} = \frac{(6.67 \times 10^{-11}\ \mathrm{N \cdot m^2/kg^2})(5.97 \times 10^{24}\ \mathrm{kg})}{(6.37 \times 10^{6}\ \mathrm{m})^2} = 9.8\ \mathrm{N/kg} = 9.8\ \mathrm{m/s^2}$$

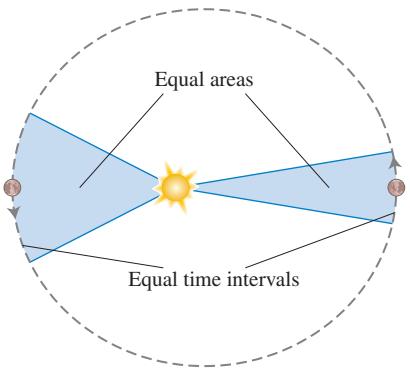
This is exactly the free-fall acceleration of objects near Earth's surface. The fact that the experimentally measured value of $9.8\ \mathrm{m/s^2}$ agrees with the value calculated using the law of gravitation gives us more confidence in the correctness of the law. This consistency check serves the purpose of a testing experiment. The expression $F_{\mathrm{E\ on\ O}} = m_{\mathrm{O}}g$ is actually a special case of the law of gravitation used to determine the gravitational force that Earth exerts on objects when near Earth's surface. Using a similar technique we can determine the free-fall acceleration of an object near the surface of the Moon ($m_{\mathrm{Moon}} = 7.35 \times 10^{22}\,\mathrm{kg}$ and $R_{\mathrm{Moon}} = 1.74 \times 10^{6}\,\mathrm{m}$) to be $1.6\ \mathrm{N/kg} = 1.6\ \mathrm{m/s^2}$.

Kepler's laws and the law of universal gravitation



About half a century before Newton's work, Johannes Kepler (1571–1630) studied astronomical data concerning the motion of the known planets and crafted three laws, called Kepler's laws of planetary motion. Newton knew about Kepler's work and applied the force equation developed for Earth-Moon interaction to the Sun and the known planets. By using the law of universal gravitation he could explain Kepler's laws. This fact contributed to scientists' confidence in the law of universal gravitation.

Kepler's first law of planetary motion The orbits of all planets are ellipses with the Sun located at one of the ellipse's foci (**Figure 5.4a**).[1]



Kepler's second law of planetary motion When a planet travels in an orbit, an imaginary line connecting the planet and the Sun continually sweeps out the same area during the same time interval, independent of the planet's distance from the Sun (Figure 5.4b).

FIGURE 5.4 Orbital models used by Kepler to develop his laws of planetary motion.

(a) The orbits of all planets are ellipses with the Sun located at one focus.

(b) An imaginary line connecting the planet and the Sun continually sweeps out the same area during the same time interval.

[1] The shape of the planetary orbits is close to circular for most of the planets. In those cases, the foci of the ellipse are very close to the center of the circular orbit that most closely approximates the ellipse.

Kepler's third law of planetary motion The square of the period T of the planet's motion (the time interval to complete one orbit) divided by the cube of the semi-major axis of the orbit (which is half the maximum diameter of an elliptical orbit or the radius r of a circular one) equals the same constant for all the known planets:

$$\frac{T^2}{r^3} = K \tag{5.15}$$

Newton was able to use his laws of motion and gravitation to derive all three of Kepler's laws of planetary motion. In addition, astronomers later used Newton's law of universal gravitation to predict the locations of the then-unknown planets Neptune and Pluto. They did it by observing subtle inconsistencies between the observed orbits of known planets and the predictions of the law of universal gravitation. At present, physicists and engineers use the law of universal gravitation to decide how to launch satellites into their desired orbits and how to successfully send astronauts to the Moon and beyond. Newton's law of universal gravitation has been tested countless times and is consistent with observations to a very high degree of accuracy.

Newton's law of universal gravitation The magnitude of the attractive gravitational force that an object with mass m_1 exerts on an object with mass m_2 separated by a center-to-center distance r is:

$$F_{g\,1\text{ on }2} = G\frac{m_1 m_2}{r^2} \tag{5.14}$$

where $G = 6.67 \times 10^{-11}\ \mathrm{N \cdot m^2/kg^2}$ is known as the gravitational constant.

However, just because this relationship is called a "law" does not mean that the law is always valid. Every mathematical expression in physics is applicable only for certain circumstances, and the law of universal gravitation is no exception.

Limitations of the law of universal gravitation

The law of universal gravitation in the form of Eq. (5.14) only applies to objects with spherical symmetry or whose separation distance is much bigger than their size. An object that is spherically symmetric has the shape of a perfect sphere and a density that only varies with distance from its center. In these cases, we can model the objects as though all of their mass was located at a single point at their centers. However, if the objects are not spherically symmetric and are close enough to each other so that they cannot be modeled as point-like particles, then the law of universal gravitation does not apply directly. But using calculus, we can divide each object into a collection of very small point-like objects and use the law of universal gravitation on each pair to add by integration the forces of the small point-like particles on each other.

However, even with calculus, there are details of some motion for which the law cannot account. When astronomers made careful observations of the orbit of Mercury, for example, they noticed that its orbit exhibited some patterns that the law of universal gravitation could not explain. It wasn't until the early 20th century, when Einstein constructed a more advanced theory of gravity, that scientists could predict all of the details of the motion of Mercury.

Are astronauts weightless?

The Moon orbits Earth due to the gravitational force that provides the necessary radial acceleration. It is Earth's natural *satellite*, a celestial object that orbits a bigger celestial object (usually a planet). Artificial satellites are objects that are placed in orbit by

humans. The first artificial satellite was launched in 1957, and since then thousands of satellites have been sent into orbit. Earth satellites make worldwide communication possible, allow us to monitor Earth's surface and the weather, help us find our way to unknown destinations with our global positioning systems (GPS), and provide access to hundreds of television stations. One such satellite is the International Space Station.

We are all familiar with videos of astronauts floating in the International Space Station. News reports commonly say that the astronauts are weightless or experience zero gravity. Is this true?

QUANTITATIVE EXERCISE 5.7 **Are astronauts in the International Space Station weightless?**

The International Space Station orbits about 0.40×10^6 m (250 miles) above Earth's surface, or $(6.37 + 0.40) \times 10^6$ m $= 6.77 \times 10^6$ m from Earth's center. Compare the force that Earth exerts on an astronaut in the station to the force when he is on Earth's surface.

Represent mathematically The gravitational force that Earth exerts on the astronaut (system) in the space station is

$$F_{\text{E on A in station}} = G\frac{m_E m_A}{(r_{\text{station-Earth}})^2}$$

where $r_{\text{station-Earth}} = 6.77 \times 10^6$ m is the distance from Earth's center to the astronaut in the space station. The gravitational force exerted by Earth on the astronaut when on Earth's surface is

$$F_{\text{E on A on Earth's surface}} = G\frac{m_E m_A}{(r_{\text{surface-Earth}})^2}$$

where $r_{\text{surface-Earth}} = 6.37 \times 10^6$ m is the distance from the center of Earth to its surface. To compare these two forces, take their ratio:

$$\frac{F_{\text{E on A in station}}}{F_{\text{E on A on Earth's surface}}} = \frac{G\dfrac{m_E m_A}{r^2_{\text{station-Earth}}}}{G\dfrac{m_E m_A}{r^2_{\text{surface-Earth}}}} = \left(\frac{r_{\text{surface-Earth}}}{r_{\text{station-Earth}}}\right)^2$$

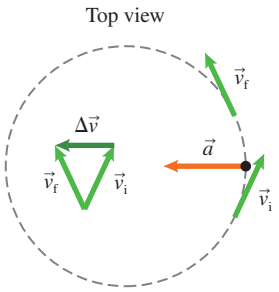
Solve and evaluate Inserting the appropriate values gives

$$\frac{F_{\text{E on A in station}}}{F_{\text{E on A on Earth's surface}}} = \left(\frac{6.37 \times 10^6 \text{ m}}{6.77 \times 10^6 \text{ m}}\right)^2 = 0.89$$

The gravitational force that Earth exerts on the astronaut when in the space station is just 11% less than the force exerted on him when on Earth's surface. The astronaut is far from "weightless."

Try it yourself At what distance from Earth's center should a person be so that her weight is half her weight when on Earth's surface?

Answer $1.4R_E$.



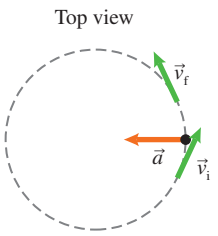
Quantitative Exercise 5.7 shows that astronauts are not actually weightless while in the International Space Station. So why do they float? Remember that Earth exerts a gravitational force on both the astronaut and the space station. This force causes them both to fall toward Earth at the same rate while they fly forward, thus staying on the same circular path. Both the astronaut and the space station are in free fall. As a result, if the astronaut stood on a scale placed on the floor of the orbiting space station, her weight, according to the scale, would be zero. The same thing happens on Earth when you stand on a scale inside an elevator that is in free fall, falling at the acceleration $\vec{g}$. Since both you and the elevator fall with the same acceleration, you do not press on the scale, and the scale does not press on you; it reads zero.

The confusion occurs because in physics weight is a shorthand way of referring to the gravitational force being exerted on an object, not the reading of a scale. The scale measures the normal force it exerts on any object with which it is in contact. So astronauts are not "weightless"; the word is actually being misused.

REVIEW QUESTION 5.5 A friend says he has heard that the Moon is falling toward Earth. What can you tell your friend to reassure him that all is well?

Summary

Velocity change method to find the direction of acceleration We can estimate the direction of an object's acceleration as it passes a point along its circular path by drawing an initial velocity vector v_i just before that point and a final velocity vector v_f just after that point. We place the vectors tail to tail and draw a velocity change vector from the tip of the initial to the tip of the final velocity. The acceleration points in the direction of the velocity change vector. (Section 5.2)



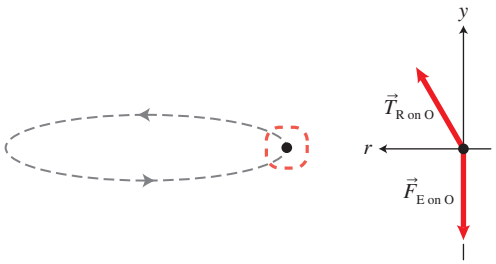
$$\vec{v}_i + \Delta\vec{v} = \vec{v}_f$$

or

$$\Delta\vec{v} = \vec{v}_f - \vec{v}_i$$

$$\vec{a} = \frac{\Delta\vec{v}}{\Delta t} = \frac{\vec{v}_f - \vec{v}_i}{t_f - t_i}$$

Radial acceleration for constant speed circular motion An object moving at constant speed along a circular path has acceleration that points toward the center of the circle and has a magnitude a_r that depends on its speed v and the radius r of the circle. (Section 5.3)

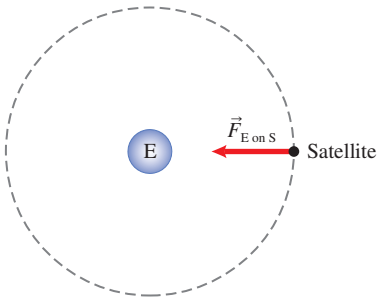


$$a_r = \frac{v^2}{r} \qquad \text{Eq. (5.3)}$$

Period and radial acceleration The radial acceleration can also be expressed using the period T of circular motion, the time interval needed for an object to complete one trip around the circle. (Section 5.3)

$$T = \frac{2\pi r}{v} \qquad \text{Eq. (5.4)}$$

$$a_r = \frac{4\pi^2 r}{T^2} \qquad \text{Eq. (5.5)}$$



Sum of the forces for constant speed circular motion The sum of the forces exerted on an object during constant speed circular motion points in the positive radial direction toward the center of the circle. The object's acceleration is the sum of the radial components of all forces exerted on an object divided by its mass—consistent with Newton's second law. In addition, for horizontal circular motion, you sometimes analyze the vertical y-components of forces exerted on an object. (Sections 5.1 and 5.4)

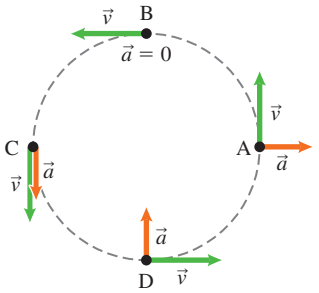
$$a_r = \frac{\Sigma F_r}{m} \quad \text{or} \quad ma_r = \Sigma F_r \qquad \text{Eq. (5.6)}$$

$$ma_y = \Sigma F_y = 0 \qquad \text{Eq. (5.7)}$$

Law of universal gravitation This force law is used primarily to determine the magnitude of the force that the Sun exerts on planets or that planets exert on satellites or on moons. The force depends on the masses of the objects and on their center-to-center separation r. (Section 5.5)

$$F_{g\,1\text{ on }2} = G\frac{m_1 m_2}{r^2} \qquad \text{Eq. (5.14)}$$

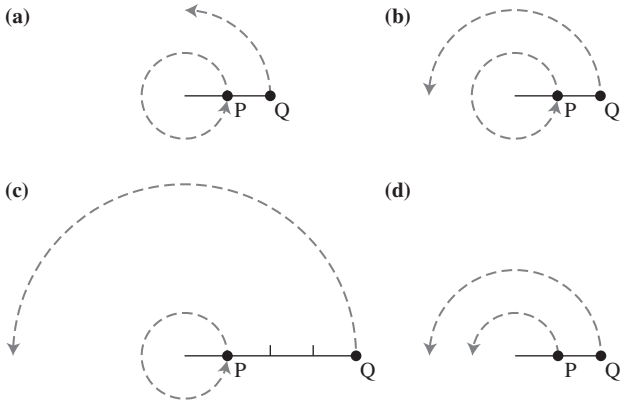
G is the gravitational constant,



$$G = 6.67 \times 10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2$$

Questions

Multiple Choice Questions



1. Which of the objects below is accelerating?
   (a) Object moving at constant speed along a straight line
   (b) Object moving at constant speed in a circle
   (c) Object slowing down while moving in a straight line
   (d) Both b and c describe accelerating objects.
2. The circle in **Figure Q5.2** represents the path followed by an object moving at constant speed. At four different positions on the circle, the object's motion is described using velocity and acceleration arrows. Choose the location where the descriptions are correct.
   (a) Point A (b) Point B
   (c) Point C (d) Point D

FIGURE Q5.2

3. One of your classmates drew a force diagram for a pendulum bob at the bottom of its swing. He put a horizontal force arrow in the direction of the velocity. Evaluate his diagram by choosing from the statements below.
   (a) He is incorrect since the force should point partly forward and tilt partly down.
   (b) He is incorrect since there are no forces in the direction of the object's velocity.
   (c) He is correct since any moving object has a force in the direction of its velocity.
   (d) He is correct but he also needs to add an outward (down) force.
4. Why is it difficult for a high-speed car to negotiate an unbanked turn?
   (a) A huge force is pushing the car outward.
   (b) The magnitude of the static friction force might not be enough to provide the necessary radial acceleration.
   (c) The sliding friction force is too large.
   (d) The faster the car moves, the harder it is for the driver to turn the steering wheel.
5. How does a person standing on the ground explain why you, sitting on the left side of a slippery back car seat, slide to the right when the car makes a high-speed left turn?
   (a) You tend to move in a straight line and thus slide with respect to the seat that is moving to the left under you.
   (b) There is a net outward force being exerted on you.
   (c) The force of motion propels you forward.
   (d) The car seat pushes you forward.
6. A pilot performs a vertical loop-the-loop at constant speed. The pilot's head is always pointing toward the center of the circle. Where is a pilot blackout more likely to occur?
   (a) At the top of the loop
   (b) At the bottom of the loop
   (c) At both top and bottom
   (d) None of the answers is correct.
7. Why is the following an inaccurate statement about blackout? "As the *g* forces climb up toward 7 *g*'s, ..."
   (a) There is no such thing as a *g* force.
   (b) 7 *g*'s is not a big force.
   (c) *g* forces are constant and do not climb.
   (d) *g* forces are not responsible for blackout but can cause dizziness.
8. Two point-like objects P and Q are undergoing circular motion at constant speeds. **Figure Q5.8** shows four possible combinations of paths for the two objects during the same time interval. Choose which is correct for
   i. the periods of the objects to be equal,
   ii. the speeds of the objects to be equal, and
   iii. the radial accelerations of the objects to be equal.

FIGURE Q5.8

9. Compare the magnitude of the normal force of a car seat on you with the magnitude of the force that Earth exerts on you when the car moves across the bottom of a dip in the road.
   (a) The normal force is more than Earth's gravitational force.
   (b) The normal force is less than Earth's gravitational force.
   (c) The two forces are equal.
   (d) It depends on whether the car is moving right or left.
10. If you put a penny on the center of a rotating turntable, it does not slip. However, if you place the penny near the edge, it is likely to slip off. Which answer below explains this observation?
    (a) The penny moves faster at the edge and hence needs a greater force to keep it moving.
    (b) The edge is more slippery since the grooves are farther apart.
    (c) The radial acceleration is greater at the edge and the friction force is not enough to keep the penny in place.
    (d) The outward force responsible for slipping is greater at the edge than at the middle.
11. Where on Earth's surface would you expect to experience the greatest radial acceleration as a result of Earth's rotation?
    (a) On the poles
    (b) On the equator
    (c) On the highest mountain
    (d) Since all points of Earth have the same period of rotation, the acceleration is the same everywhere.
12. What observational data might Newton have used to decide that the gravitational force is inversely proportional to the distance squared between the centers of objects?
    (a) The data on the acceleration of falling apples
    (b) The data describing the Moon's orbit (period and radius) and the motion of falling apples
    (c) The data on comets
    (d) The data on moonrise and moonset times
13. What observations combined with his second and third laws helped Newton decide that the gravitational force of one object on another object is directly proportional to the product of the masses of the interacting objects?
    (a) The data on the acceleration of falling apples
    (b) The data on Moon phases
    (c) The data on comets
    (d) The data on moonrise and moonset times
14. What would happen to the force exerted by the Sun on Earth if the Sun shrank and became half its present size while retaining the same mass?
    (a) The force would be half the present force.
    (b) The force would be one-fourth of the present force.
    (c) The force would double.
    (d) The force would stay the same.

15. James fixes a camera on a tripod and takes several photos of the full Moon. **Figure Q5.15** shows two photos taken during a time interval in which the Moon seems to moves one Moon diameter to the right. Which phenomenon is mainly responsible for this observed motion of the Moon?
    (a) The rotation of Earth around its axis
    (b) The revolution of Earth around the Sun
    (c) The revolution of the Moon around Earth
    (d) The motion of tectonic plates on Earth

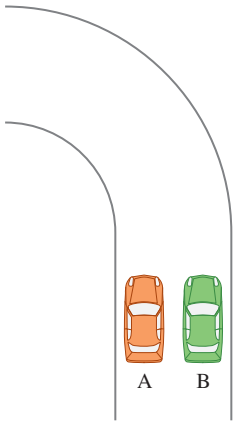


FIGURE Q5.15

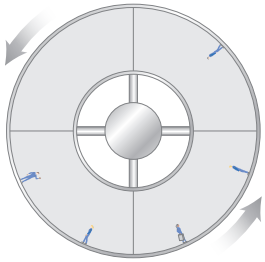
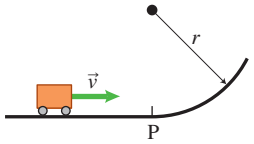
Conceptual Questions



16. Your friend says that an object weighs less on Jupiter than on Earth as Jupiter is far away from the center of Earth. Do you agree or disagree?
17. Your friend says that when an object is moving in a circle, there is a force pushing it out away from the center. Why would he say this? Do you agree or disagree? If you disagree, how would you convince your friend of your opinion?
18. Describe three everyday phenomena that are consistent with your knowledge of the dynamics of circular motion. Specify where the observer is. Then find an observer who will not be able to explain the same phenomena using the knowledge of Newton's laws and circular motion.
19. Two identical cars are moving with equal speeds on a wet road toward a turn, as shown in **Figure Q5.19**. Which car is more likely to slide off the road during the turn and why, assuming their speeds remain unchanged?
    (a) The two cars are equally likely to slide off the road because their masses are equal.
    (b) The two cars are equally likely to slide off the road because their speeds are equal.
    (c) Car B because it is closer to the outer side of the turn
    (d) Car B because the distance it travels around the turn is larger
    (e) Car A because it moves through the turn with a smaller radius
    (f) Car A because the distance it travels around the turn is smaller

FIGURE Q5.19



20. Astronauts on the space station orbiting Earth are said to be in "zero gravity." Do you agree or disagree? If you disagree, why?
21. In the movies you often see space stations with "artificial gravity." They look like big doughnuts rotating around an axis perpendicular to the plane of the doughnut (see **Figure Q5.21**). People walking on the outer rim inside the turning space station feel the same gravitational effects as if they were on Earth. How does such a station work to simulate artificial gravity?

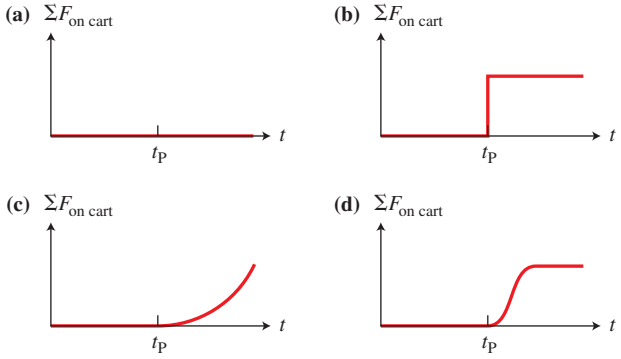


FIGURE Q5.21

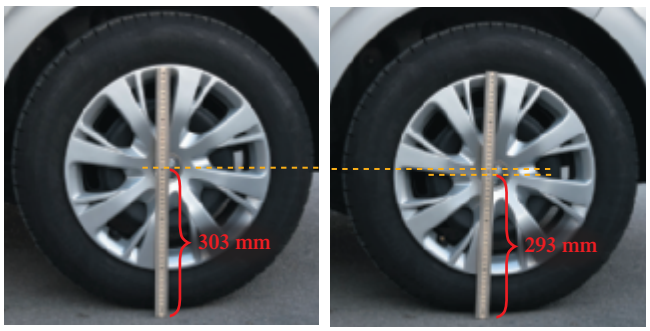
22. Give one example of a situation in which an object moves at constant speed and has zero acceleration and another of a situation in which the object moves at constant speed and has a nonzero acceleration.
23. Name a planet on which you would weigh less than on Earth. Name a planet on which you would weigh more than on Earth. Explain how you know.
24. A motorized cart is moving at a constant speed along a horizontal surface that at point P smoothly changes from being horizontal to rising upward in a circular arc (see **Figure Q5.24**). The cart passes point P at time t_P while maintaining the same constant speed v. Which graph correctly shows the time dependence of the sum of the forces exerted on the cart as it passes the point P, assuming the cart is a point-like object?

FIGURE Q5.24

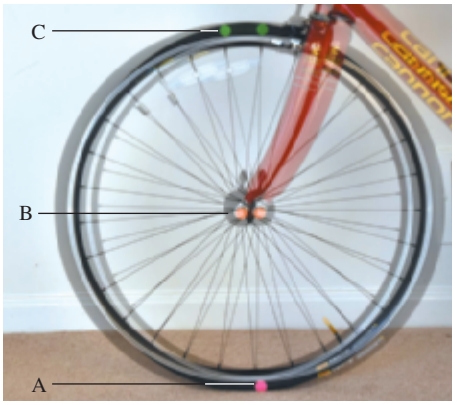
Problems



Below, BIO indicates a problem with a biological or medical focus. Problems labeled EST ask you to estimate the answer to a quantitative problem rather than derive a specific answer. Asterisks indicate the level of difficulty of the problem. Problems with no * are considered to be the least difficult. A single * marks moderately difficult problems. Two ** indicate more difficult problems.

5.1–5.3 Qualitative dynamics of circular motion, Analyzing velocity change for circular motion, and Radial acceleration and period

1. **Mountain biker** While mountain biking, you first move at constant speed along the bottom of a trail's circular dip and then at constant speed across the top of a circular hump. Assume that you and the bike are a system. Determine the direction of the acceleration at each position and construct a force diagram for each position (consistent with the direction of the acceleration). Compare at each position the magnitude of the force of the surface on the bike with the force Earth exerts on the system.
2. * You swing a rock tied to a string in a vertical circle. (a) Determine the direction of the acceleration of the rock as it passes the lowest point in its swing. Construct a consistent force diagram for the rock as it passes that point. How does the force that the string exerts on the rock compare to the force that Earth exerts on the rock? Explain. (b) Repeat this analysis as best you can for the rock as it passes the highest point in the swing. (c) If the string is tied around your finger, when do you feel a stronger pull—when the rock is at the bottom of the swing or at the top? Explain.
3. * **Loop-the-loop** You ride a roller coaster with a loop-the-loop. Compare *as best you can* the normal force that the seat exerts on you to the force that Earth exerts on you when you are passing the bottom of the loop and the top of the loop. Justify your answers by determining the direction of acceleration and constructing a force diagram for each position. Make your answers consistent with Newton's second law.



4. You start an old record player and notice a bug on the surface close to the edge of the record. The record has a diameter of 12 inches and completes 33 revolutions each minute. (a) What are the speed and the acceleration of the bug? (b) What would the bug's speed and acceleration be if it were halfway between the center and the edge of the record?
5. Determine the acceleration of Earth due to its motion around the Sun. What do you need to assume about Earth to make the calculation? How does this acceleration compare to the acceleration of free fall on Earth?
6. The Moon is an average distance of 3.8×10^8 m from Earth. It circles Earth once each 27.3 days. (a) What is its average speed? (b) What is its acceleration? (c) How does this acceleration compare to the acceleration of free fall on Earth?
7. **Aborted plane landing** You are on an airplane that is landing. The plane in front of your plane blows a tire. The pilot of your plane is advised to abort the landing, so he pulls up, moving in a semicircular upward-bending path. The path has a radius of 500 m with a radial acceleration of 17 m/s^2. What is the plane's speed?
8. BIO **Ultracentrifuge** You are working in a biology lab and learning to use a new ultracentrifuge for blood tests. The specifications for the centrifuge say that a red blood cell rotating in the ultracentrifuge moves at 470 m/s and has a radial acceleration of 150,000 g's (that is, 150,000 times 9.8 m/s^2). The radius of the centrifuge is 0.15 m. You wonder if this claim is correct. Support your answer with a calculation.
9. * EST A tire-pressure monitoring system warns you with a dashboard alert when one of your car tires is significantly underinflated, possibly creating unsafe driving conditions. How does the car know when to turn on the alert? Many cars have sensors that measure the period of rotation of each wheel. Based on the period, the car's computer determines the relative size of the tires when the car is moving at a certain speed. (a) Explain how the period of the wheel rotation is related to the size of the tire. (b) Derive a mathematical equation that relates the period T of the wheel rotation to the tire radius r and the speed v of the car. (c) **Figure P5.9** shows a properly inflated tire (left) and an underinflated tire (right) of the same car. Estimate the percent change of the period of the underinflated tire compared to the properly inflated tire. (d) Estimate the distance this car would have to travel for the difference between the numbers of turns of the two wheels to be equal to one turn. Which will undergo more turns, the underinflated or the properly inflated tire?

FIGURE P5.9

10. * Imagine that you are standing on a horizontal rotating platform in an amusement park (like the platform for a merry-go-round). The period of rotation and the radius of the platform are given, and you know your mass. Make a list of the physical quantities you could determine using this information, and describe how you would determine them.
11. * Rolling is a combination of linear and circular motion. In order to study rolling motion, we perform the following experiment. We mark three points A, B, and C on a bicycle wheel and observe how these points move while the bicycle is pushed forward 2 cm, a distance much smaller than the radius of the wheel. **Figure P5.11** shows a long-exposure photo of the experiment. The camera (i.e., the observer) is standing still on the ground. A is the point where the wheel is initially touching the ground, B is the point at the wheel's axis, and C is the point on the top of the wheel, directly above point A. (a) Determine the displacements of points A, B, and C as observed by the stationary observer. (Hint: Use similar triangles.) (b) Using your answers from part (a), determine the speed of the points A, B, and C with respect to the ground for the bicycle that is moving at constant speed v. How would the answers to part (b) change if the observer were moving in the same direction as the bicycle but (c) with the same speed as the bicycle or (d) twice as fast as the bicycle?

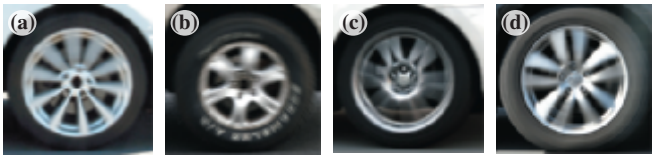


FIGURE P5.11

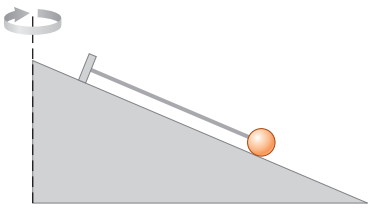
12. ** **Figure P5.12** shows photos of car wheels that were obtained in four different ways:
    i. A person standing on the sidewalk took a photo of a car that was passing by.
    ii. A person in a moving car took a photo of another car. Both cars were moving with the same speed.
    iii. A person in a moving car took a photo of another car that was moving faster than the photographer's car.
    iv. A person in a moving car took a photo of another car that was moving slower than the photographer's car.

    Match each photo (a) to (d) with the corresponding photographing procedure. [Hint: If you have difficulties with this problem, solve the previous problem.]

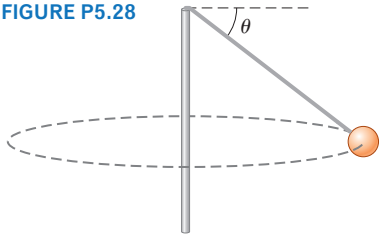
FIGURE P5.12



13. * Three people are standing on a horizontally rotating platform in an amusement park. One person is almost at the edge, the second one is $(3/5)R$ from the center, and the third is $(1/2)R$ from the center. Compare their periods of rotation, their speeds, and their radial accelerations.
14. * Consider the scenario described in Problem 5.13. If the platform speeds up, who is more likely to have trouble staying on the platform? Support your answer with a force diagram and describe the assumptions that you made.

15. * You want to determine the radial acceleration of a friend who is standing on the rotating platform of a merry-go-round. You have a stopwatch and a measuring tape. Which of the following procedures would best serve your task?
    (a) Measure the distance d between the point where the person is standing and the axis of rotation, count the number of rotations N of the platform in 20 seconds, and calculate $d \cdot \left(\frac{2\pi N}{20\text{ s}}\right)^2$.
    (b) Measure the distance d between the point where the person is standing and the edge of the platform, count the number of rotations N of the platform in 20 seconds, and calculate $d \cdot \left(\frac{2\pi N}{20\text{ s}}\right)^2$.
    (c) Measure the distance d between the point where the person is standing and the axis of rotation, measure the time t for 20 revolutions of the platform, and calculate $d \cdot \left(\frac{20}{2\pi t}\right)^2$.
16. **Ferris wheel** You are sitting on a rotating Ferris wheel. Draw a force diagram for yourself when you are at the bottom of the circle and when you are at the top.
17. * EST Estimate the radial acceleration of the foot of a college football player in the middle of punting a football.
18. * EST Estimate the radial acceleration of the toe at the end of the horizontally extended leg of a ballerina doing a pirouette.

5.4 Skills for analyzing processes involving circular motion



19. * Is it safe to drive your 1600-kg car at speed 27 m/s around a level highway curve of radius 150 m if the effective coefficient of static friction between the car and the road is 0.40? Explain.
20. * You are fixing a broken rotary lawn mower. The blades on the mower turn 50 times per second. What is the magnitude of the force needed to hold the outer 2 cm of the blade to the inner portion of the blade? The outer part is 21 cm from the center of the blade, and the mass of the outer portion is 7.0 g.
21. * Your car speeds around the 80-m-radius curved exit ramp of a freeway. A 70-kg student holds the armrest of the car door, exerting a 220-N force on it in order to prevent himself from sliding across the vinyl-covered back seat of the car and slamming into his friend. How fast is the car moving in meters per second and miles per hour? What assumptions did you make?
22. How fast do you need to swing a 200-g ball at the end of a string in a horizontal circle of 0.5-m radius so that the string makes a 34° angle relative to the horizontal? What assumptions did you make?
23. ** A small ball is attached by a string to a smooth incline, as shown in Figure P5.23. The incline is initially at rest. (a) Draw a force diagram for the ball and label all the forces. (b) Describe what happens to the magnitude of each force (does it increase, decrease, or remain the same?) when the incline (with the ball and the string) rotates around the vertical axis at constant speed.

FIGURE P5.23

24. A coin rests on a record 0.15 m from its center. The record turns on a turntable that rotates at variable speed. The coefficient of static friction between the coin and the record is 0.30. What is the maximum coin speed at which it does not slip?
25. * **Roller coaster ride** A roller coaster car travels at speed 8.0 m/s over a 12-m-radius vertical circular hump. What is the magnitude of the upward force that the coaster seat exerts on a 48-kg woman passenger?
26. ** A person sitting in a chair (combined mass 80 kg) is attached to a 6.0-m-long cable. The person moves in a horizontal circle. The cable angle θ is 62° below the horizontal. What is the person's speed? Note: The radius of the circle is not 6.0 m.
27. * A car moves around a 50-m-radius highway curve. The road, banked at 10° relative to the horizontal, is wet and icy so that the coefficient of friction is approximately zero. At what speed should the car travel so that it makes the turn without slipping?
28. * A 20.0-g ball is attached to a 120-cm-long string and moves in a horizontal circle (see Figure P5.28). The string exerts a force on the ball that is equal to 0.200 N. What is the angle θ?

FIGURE P5.28

29. A 50-kg ice skater goes around a circle of radius 5.0 m at a constant speed of 3.0 m/s on a level ice rink. What are the magnitude and direction of the horizontal force that the ice exerts on the skates?
30. * A car traveling at 10 m/s passes over a hill on a road that has a circular cross section of radius 30 m. What is the force exerted by the seat of the car on a 60-kg passenger when the car is passing the top of the hill?
31. A 1000-kg car is moving at 30 m/s around a horizontal level curved road whose radius is 100 m. What is the magnitude of the frictional force required to keep the car from sliding?
32. * **Equation Jeopardy 1** Describe using words, a sketch, a velocity change diagram, and a force diagram two situations whose mathematical description is presented below.

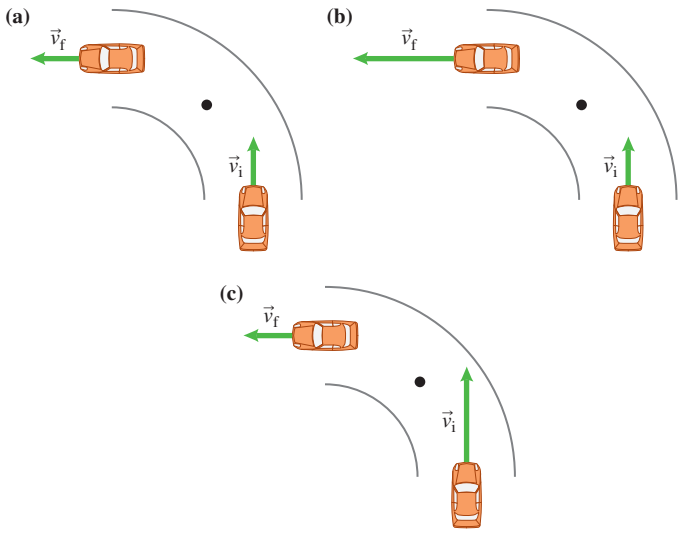
$$700\text{ N} - (30\text{ kg})(9.8\text{ m/s}^2) = \frac{(30\text{ kg})v^2}{12\text{ m}}$$

33. * **Equation Jeopardy 2** Describe using words, a sketch, a velocity change diagram, and a force diagram two situations whose mathematical description is presented below.

$$\frac{(2.0\text{ kg})(4.0\text{ m}^2/\text{s}^2)}{r} = 0.4 \times (2.0\text{ kg}) \times (9.8\text{ N/kg})$$

34. ** **Banked curve raceway design** You need to design a banked curve at the new circular Super 100 Raceway. The radius of the track is 800 m, and cars typically travel at speed 160 mi/h. What feature of the design ensures that all racecars can move around the track safely in any weather? (a) Provide a quantitative answer. (b) List your assumptions and describe whether the number you provided will increase or decrease if the assumption is not valid.
35. * A circular track is in a horizontal plane, has a radius of r meters, and is banked at an angle θ above the horizontal. (a) Develop an expression for the speed a person should Rollerblade on this track so that she needs zero friction to prevent her from sliding sideways off the track. (b) Should another person move faster or slower if her mass is 1.3 times the mass of the first person? Justify your answer.
36. ** Design a quantitative test for Newton's second law as applied to constant speed circular motion. Describe the experiment and provide the analysis needed to make a prediction using the law.

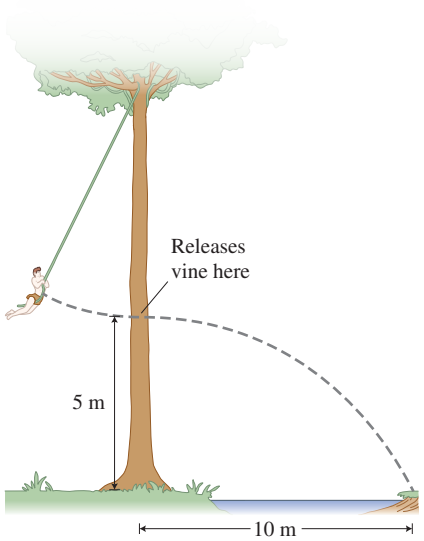
5.5 The law of universal gravitation



37. * Your friend says that the force that the Sun exerts on Earth is much larger than the force that Earth exerts on the Sun. (a) Do you agree or disagree with this opinion? (b) If you disagree, how would you convince your friend of your opinion?
38. Determine the gravitational force that (a) the Sun exerts on the Moon, (b) Earth exerts on the Moon, and (c) the Moon exerts on Earth. List at least two assumptions for each force that you made when you calculated the answers.
39. * (a) What is the ratio of the gravitational force that Earth exerts on the Sun in the winter and the force that it exerts in the summer? (b) How many correct answers can you give for part (a)? (Hint: Earth's orbit is an ellipse with the Sun located at one of the foci of the ellipse. Think about the location of the observer on Earth.)
40. ** EST Estimate (a) the average distance between Earth and the Moon and (b) the diameter of the Moon, using the following data: the period of the Moon's revolution around Earth ($T_M \approx 28$ days), the average radius of Earth ($R_E = 6400$ km), free-fall acceleration of objects near Earth's surface ($g = 9.8\text{ m/s}^2$), and the data in Figure Q5.15. The numbers on the photos are the times when the photos were taken (hh:mm:ss). Indicate any assumptions that you made. (Hint: Use Kepler's third law.)

41. * EST The average radius of Earth's orbit around the Sun is 1.5×10^8 km. The mass of Earth is 5.97×10^{24} kg, and it makes one orbit in approximately 365 days. (a) What is Earth's speed relative to the Sun? (b) Estimate the Sun's mass using Newton's law of universal gravitation and Newton's second law. What assumptions did you need to make?
42. * The Moon travels in a 3.8×10^5-km-radius orbit about Earth. Earth's mass is 5.97×10^{24} kg. Determine the period T for one Moon orbit about Earth using Newton's law of universal gravitation and Newton's second law. What assumptions did you make?
43. * Determine the ratio of Earth's gravitational force exerted on an 80-kg person when at Earth's surface and when 1000 km above Earth's surface. The radius of Earth is 6370 km.
44. * Determine the magnitude of the gravitational force Mars would exert on your body if you were on the surface of Mars.
45. * When you stand on a bathroom scale here on Earth, it reads 540 N. (a) What would your mass be on Mars, Venus, and Saturn? (b) What is the magnitude of the gravitational force each planet would exert on you if you stood on their surface? (c) What assumptions did you make?
46. The free-fall acceleration on the surface of Jupiter, the most massive planet, is 24.79 m/s^2. Jupiter's radius is 7.0×10^4 km. Use Newtonian ideas to determine Jupiter's mass.
47. * A satellite moves in a circular orbit a distance of 1.6×10^5 m above Earth's surface. Determine the speed of the satellite.
48. * Mars has a mass of 6.42×10^{23} kg and a radius of 3.40×10^6 m. Assume a person is standing on a bathroom scale on the surface of Mars. Over what time interval would Mars have to complete one rotation on its axis to make the bathroom scale have a zero reading?
49. * Determine the speed a projectile must reach in order to become an Earth satellite. What assumptions did you make?
50. ** Determine the distance above Earth's surface to a satellite that completes two orbits per day. What assumptions did you make?
51. *Determine the period of an Earth satellite that moves in a circular orbit just above Earth's surface. What assumptions did you need to make?
52. * A spaceship in outer space has a doughnut shape with 500-m outer radius. The inhabitants stand with their heads toward the center and their feet on an outside rim (see Figure Q5.21). Over what time interval would the spaceship have to complete one rotation on its axis to make a bathroom scale have the same reading for the person in space as when on Earth's surface? Indicate any assumptions that you made.

General Problems

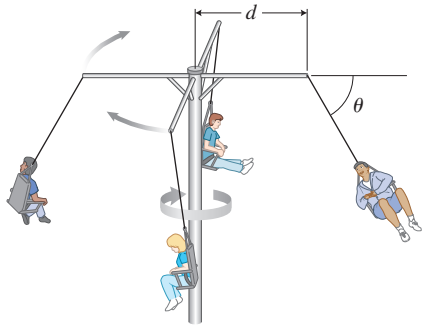


53. * Using the velocity change method from Physics Tool Box 5.1, find the direction of a car's acceleration at the marked point in the middle of the circular turn shown in **Figure P5.53** for the three cases (a) the car is moving at constant speed, (b) the car is speeding up, and (c) the car is slowing down.

FIGURE P5.53

54. * **Loop-the-loop** You have to design a loop-the-loop for a new amusement park so that when each car passes the top of the loop inverted (upside-down), each seat exerts a force against a passenger's bottom that has a magnitude equal to 1.5 times the gravitational force that Earth exerts on the passenger. Choose some reasonable physical quantities so these conditions are met. Show that the loop-the-loop will work equally well for passengers of any mass.
55. ** **A Tarzan swing** Tarzan (mass 80 kg) swings at the end of an 8.0-m-long vine (**Figure P5.55**). When directly under the vine's support, he releases the vine and flies across a swamp. When he releases the vine, he is 5.0 m above the swamp and 10.0 m horizontally from the other side. Determine the force the vine exerts on him at the instant before he lets go (the vine is straight down when he lets go).

FIGURE P5.55



56. * (a) If the masses of Earth and the Moon were both doubled, by how much would the radius of the Moon's orbit about Earth have to change if its speed did not change? (b) By how much would its speed have to change if its radius did not change? Justify each answer.
57. * EST Estimate the radial acceleration of the tread of a car tire. Indicate any assumptions that you made.
58. ** EST Estimate the force exerted by the tire on a 10-cm-long section of the tread of a tire as the car travels at speed 80 km/h. Justify any numbers used in your estimate.
59. ** EST Estimate the maximum radial force that a football player's leg needs to exert on his foot when swinging the leg to punt the ball. Justify any numbers that you use.
60. * EST Estimate the force exerted by the wheel of a car on the 20-g tire valve while the car is driving on a highway (see **Figure P5.60**). Justify any numbers used in your estimate.

FIGURE P5.60

61. Lucia's bathroom scale on the equator reads 110 lb when she stands on it. If her mass stays the same, will the scale read more or less at the North Pole? To answer this question, (a) draw a force diagram for Lucia. (b) With the assistance of this diagram, write an expression using Newton's second law that relates the forces exerted on Lucia and her acceleration along the radial direction. (c) Decide whether the reading of the scale would be different at the North Pole. List the assumptions that you made and describe how your answer might change if those assumptions were not valid.
62. **Design 1** Design and solve a circular motion problem for a roller coaster.
63. * **Design 2** Design and solve a circular motion problem for the amusement park ride shown in **Figure P5.63**.

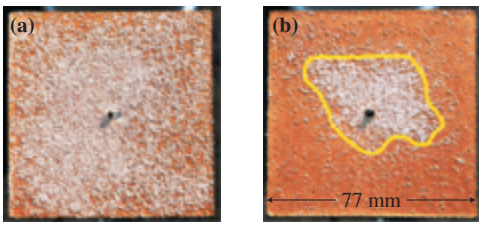


FIGURE P5.63

64. ** **Demolition** An old building is being demolished by swinging a heavy metal ball from a crane. Suppose that the 100-kg ball swings from a 20-m-long wire at speed 16 m/s as the wire passes the vertical orientation. (a) What tension force must the wire be able to withstand in order not to break? (b) Assume the ball stops after sinking 1.5 m into the wall of the building. What was the average force that the ball exerted on the wall? Indicate any assumptions you made for each part of the problem.
65. **Designing a banked roadway** You need to design a banked curve for a highway in which cars make a 90° turn moving at 50 mi/h. Indicate any assumptions you make. Describe your design.
66. * **Evaluation question** You find the following in a report about blackouts: "The acceleration that causes blackouts in fighter pilots is called the maximum *g*-force. Fighter pilots experience this force when accelerating or decelerating quickly. At high *g*'s, the pilot's blood pressure changes and the flow of oxygen to the brain rapidly decreases. This happens because the pressure outside of the pilot's body is so much greater than the pressure a human is normally accustomed to." Indicate any incorrect physics (including the application of physics to biology) that you find.
67. * Suppose that Earth rotated much faster on its axis—so fast that people were almost weightless when at Earth's surface. How long would the length of a day be on this new Earth?
68. * On Earth, an average person's vertical jump is 0.40 m. What is it on the Moon? Explain.
69. * You read in a science magazine that on the Moon, the speed of a shell leaving the barrel of a modern tank is enough to put the shell in a circular orbit above the surface of the Moon (there is no atmosphere to slow the shell). What should be the speed for this to happen? Is this number reasonable?
70. * Determining the forces between powders and surfaces (*adhesive forces*) plays an important role in several industrial applications. One method to determine adhesive forces employs the following procedure. Powder is deposited on a flat surface that was previously covered with a layer of the material under study, for example, glue. The sample is then spun very quickly for some time. During the spinning, some particles fly off the surface and some remain on it. Examining the sample after the rotation allows scientists to determine the maximum force that the surface exerted on the powder particles. (a) Explain the physics principles that are employed in this method.

Figure P5.70a shows salt crystals (cubes of average mass 0.06 mg) stuck to a piece of cardboard by a layer of glue. Figure P5.70b shows the same piece of cardboard after it was spun at 80 rotations per second about the axis of rotation shown by the black dot in center of the photos. The yellow curve surrounds the area where the salt mostly remained on the cardboard. (b) Estimate the maximum force exerted by the glue on a salt crystal in this experiment. Indicate any assumptions that you made. Note: You will need a ruler to solve this problem!

FIGURE P5.70

71. ** Isabel notices that if she places a small plastic box on a horizontal wooden disk and slowly increases the rotational frequency of the disk, the box flies off the disk at a certain rotational frequency. She investigates this phenomenon by placing the box at different distances *d* from the edge of the disk and measuring the period of disk revolution *T* when the box flies off the disk. Her data are presented in the table at right. Based on these data Isabel is able to determine the radius of the disk and the coefficient of static friction between wood and plastic. Explain how she obtains these values and determine them using her data. (Hint: First, write an expression for *T* in the limiting case when the static friction force is the largest. Then rearrange your equation to obtain a linear dependence on *d* [this does not necessarily mean that quantity that depends linearly on *d* is to the first power], draw a graph, plot the best-fit line, and determine the unknown quantities from the information that you obtain from your graph.)

d (m)	*T* (s)
0.17	0.55
0.16	0.65
0.15	0.72
0.14	0.80
0.13	0.85

Reading Passage Problems

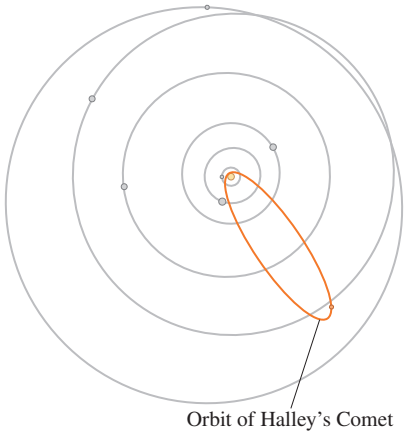
Texas Motor Speedway On October 28, 2000 Gil de Ferran set the single-lap average speed record for the then-named California Speedway—241.428 mi/h. The following year, on April 29, 2001, the Championship Auto Racing Teams (CART) organization canceled the inaugural Firestone Firehawk 600 race at the Texas Motor Speedway 2 hours before it was to start. During practice, drivers became dizzy when they reached speeds of more than 230 mph on the high-banked track. The Texas Motor Speedway has turns banked at 24° above the horizontal. By comparison, turns on the Indianapolis Motor Speedway are banked at 9°.

In qualifying runs for the race, 21 of 25 drivers complained of dizziness and disorientation. They experienced accelerations of 5.5*g* (5.5 times 9.8 m/s^2) that lasted for several seconds. Such accelerations for such long time intervals have caused pilots to black out. Blood drains from their heads to their legs as they move in circles with their heads toward the center of the circle. CART felt that the track was unsafe for their drivers. The Texas Motor Speedway had tested the track with drivers before the race and thought it was safe. The Texas Motor Speedway sued CART.

72. Why did drivers get dizzy and disoriented while driving at the Texas Motor Speedway?
    (a) The cars were traveling at over 200 mi/h.
    (b) The track was tilted at an unusually steep angle.
    (c) On turns, the drivers' blood tended to drain from their brains into veins in their lower bodies.
    (d) The *g* force pushed blood into their heads.
    (e) The combination of a and b caused c.

73. What was the time for Gil de Ferran's car to complete one lap of 1.5 mi during his record-setting drive?
(a) 16.8 s (b) 18.4 s (c) 22.4 s
(d) 25.1 s (e) 37.3 s

74. If the racecars had no help from friction, which expression below would describe the normal force of the track on the cars while traversing the 24° banked curves?
(a) $mg \cos 66°$ (b) $mg \sin 66°$ (c) $mg/\cos 66°$
(d) $mg/\sin 66°$ (e) None of these



75. For the racecars to stay on the road while traveling at high speed, how does a friction force need to be exerted?
(a) Parallel to the roadway and outward
(b) Parallel to the roadway and toward the infield
(c) Horizontally toward the center of the track
(d) Opposite the direction of motion
(e) None of the above

76. The average speed reported in the reading passage has six significant digits, implying that the speed is known to within ± 0.001 mi/h. If this is correct, which answer below is closest to the uncertainty in the time needed to travel around the 1.5-mi oval track? (Think about the percent uncertainties.)
(a) ± 0.0001 s (b) ± 0.001 s (c) ± 0.01 s
(d) ± 0.1 s (e) ± 1 s

77. What was the approximate radius of the part of the track where the drivers experienced the $5.5g$ acceleration?
(a) 40 m (b) 80 m (c) 200 m
(d) 400 m (e) 1000 m

Halley's Comet Edmond Halley was the first to realize that the comets observed in 1531, 1607, and 1682 were really one comet (now called Halley's Comet) that moved around the Sun in an elongated elliptical orbit (see **Figure 5.5**). He predicted that the peanut-shaped comet would reappear in 1757. It appeared in March 1759 (attractions to Jupiter and Saturn delayed its trip by 618 days). More recent appearances of Halley's Comet were in 1835, 1910, and 1986. It is expected again in 2061.

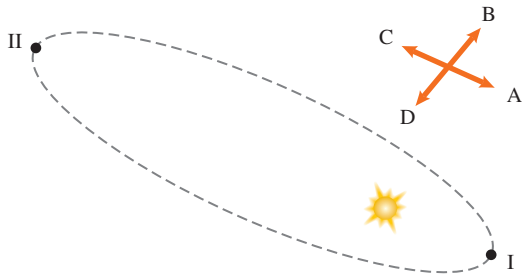


FIGURE 5.5 The elongated orbit of Halley's Comet.

The nucleus of Halley's Comet is relatively small (15 km long, 8 km wide, and 8 km thick). It has a low 2.2×10^{14}-kg mass with an average density of about 600 kg/m^3. (The density of water is 1000 kg/m^3.) The nucleus rotates once every 52 h. When Halley's Comet is closest to the Sun, temperatures on the comet can rise to about 77 °C and several tons of gas and dust are emitted each second, producing the long tail that we see each time it passes the Sun.

78. EST Use the velocity change method to estimate the comet's direction of acceleration when passing closest to the Sun (position I in **Figure P5.78**).
(a) A (b) B (c) C (d) D
(e) The acceleration is zero.

FIGURE P5.78

79. What object or objects exert forces on the comet as it passes position I (shown in Figure P5.78)?
(a) The Sun's gravitational force toward the Sun
(b) The force of motion tangent to the direction the comet is traveling
(c) An outward force away from the Sun
(d) a and b
(e) a, b, and c

80. Suppose that instead of being peanut shaped, Halley's Comet was spherical with a radius of 5.0 km (about its present volume). Which answer below is closest to what your radial acceleration would be if you were standing on the "equator" of the rotating comet?
(a) 10^{-5} m/s^2 (b) 10^{-3} m/s^2 (c) 0.1 m/s^2
(d) 10 m/s^2 (e) 1000 m/s^2

81. Approximately what gravitational force would the spherical-shaped 5-km radius comet exert on a 100-kg person on the surface of the comet?
(a) 0.06 N (b) 0.6 N (c) 6 N
(d) 60 N (e) 600 N

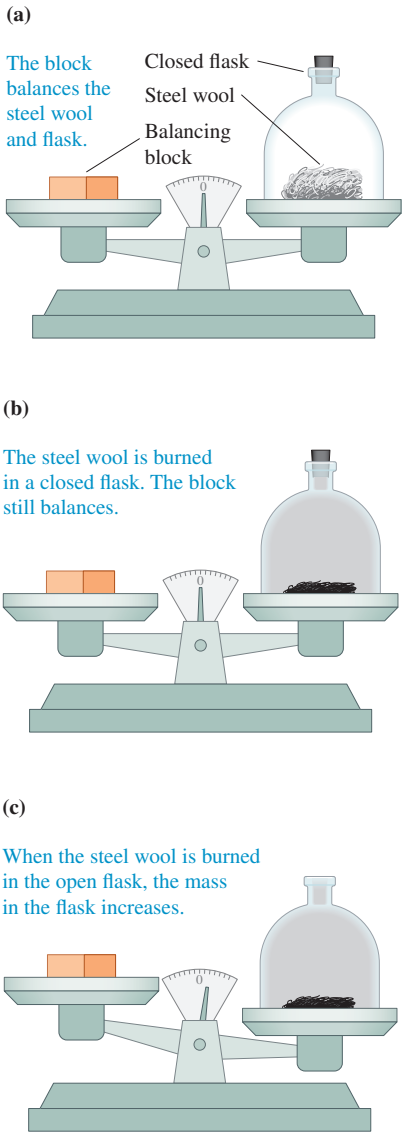
82. At its closest point, the comet is 8.77×10^{10} m from the Sun (position I in Figure P5.78). Apply Newton's second law and the law of universal gravitation to determine which answer below is closest to the comet's speed when passing position I.
(a) 1000 m/s (b) 8000 m/s (c) 20,000 m/s
(d) 40,000 m/s (e) 800,000 m/s

83. At its farthest point, the comet is 5.25×10^{12} m from the Sun (position II in Figure P5.78). Apply Newton's second law and the law of universal gravitation to determine which answer below is closest to the comet's speed when passing position II.
(a) 800 m/s (b) 5000 m/s (c) 10,000 m/s
(d) 50,000 m/s (e) 80,000 m/s

6

Impulse and Linear Momentum

Car tires push against the ground and, in turn, the ground pushes the car, accelerating it. Ship propellers push water and, in turn, the water pushes the ship, accelerating it. But how does a rocket, far above Earth's atmosphere, change velocity with no object to push against?



- **How does jet propulsion work?**
- **How can you measure the speed of a bullet?**
- **Why is radon gas in the basement dangerous?**

WE CAN USE NEWTON'S second law ($\vec{a} = \Sigma\vec{F}/m$) to relate the acceleration of a system to the forces being exerted on it. However, to use this law effectively we need quantitative information about the forces that objects exert on each other. Unfortunately, if two cars collide, we don't know the force that one car exerts on the other during the collision. When fireworks explode, we don't know the forces that are exerted on the pieces flying apart. In this chapter you will learn a new approach that helps us analyze and predict mechanical phenomena when the forces are not known.

BE SURE YOU KNOW HOW TO:

- Construct a force diagram for an object (Section 3.1).
- Use Newton's second law in component form (Section 4.2).
- Use kinematics to describe an object's motion (Section 2.9).

FIGURE 6.1 Experiments to explore the mass of a system.

6.1 Mass accounting

We begin our investigation by analyzing the physical quantity of mass. Earlier (in Chapter 3), we found that the acceleration of a system depended on its mass—the greater its mass, the less it accelerated due to the sum of the forces exerted on it. We ignored the possibility that a system's mass might change during some process. Is the mass in a system always a constant value?

You have probably observed countless physical processes in which mass seems to change. For example, the mass of a log in a campfire decreases as the log burns; the mass of a seedling increases as the plant grows. What happens to the "lost" mass from the log? Where does the seedling's increased mass come from?

A system perspective helps us understand what happens to the burning log. Remember that in physics we can choose what objects are in a system of interest. Objects outside the system interact with the system. If we choose only the log as the system, the mass of the system decreases as it burns. However, air is needed for burning. What happens to the mass if we choose the log and the surrounding air as the system?

Suppose that to explore this question we place steel wool in a closed flask on one side of a balance scale and a metal block of equal mass on the other side (**Figure 6.1a**). In one experiment, we burn the steel wool in the closed flask (the flask also contains air), forming an oxide of iron. We find that the total mass of the closed flask containing burned steel wool (iron oxide) is the same as the mass of the balancing metal block (Figure 6.1b). Next, we burn the steel wool in an open flask and observe that the mass of that flask increases (Figure 6.1c). The steel wool in the open flask absorbs some oxygen from the air as it burns.

Eighteenth-century French chemist Antoine Lavoisier actually performed such experiments. He realized that the choice of the system was very important. Lavoisier defined an **isolated system** as a group of objects that interact with each other but not with objects outside the system. The mass of an isolated system is the sum of the masses of all objects in the system. He then used the concept of an isolated system to summarize his (and our) experiments in the following way:

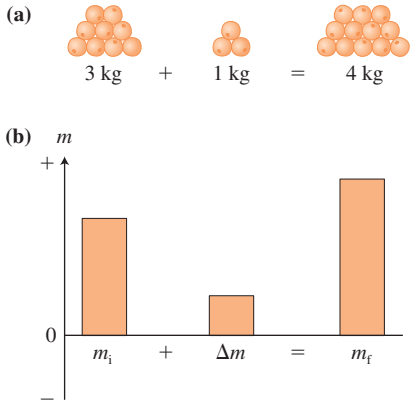
Law of constancy of mass in an isolated system When a system of objects is isolated (a closed container system), its mass equals the sum of the masses of its components and does not change—it remains constant in time.

When the system is not isolated (an open container system), the mass might change. However, this change is not random—it is always equal to the amount of mass leaving or entering the system from the environment.

Thus, even when the mass of a system is not constant, we can keep track of the changes if we take into account how much is entering or leaving the system:

$$\left(\begin{array}{c}\textit{initial}\text{ mass of}\\ \text{system at earlier clock}\\ \text{reading}\end{array}\right)+\left(\begin{array}{c}\textit{new}\text{ mass entering or}\\ \text{leaving system between}\\ \text{the two clock readings}\end{array}\right)=\left(\begin{array}{c}\textit{final}\text{ mass of}\\ \text{system at later clock}\\ \text{reading}\end{array}\right)$$

The above equation describes the change of mass in any system. The mass is constant if there is no flow of mass in or out of the system; the mass changes in a predictable way if there is some flow of mass between the system and the environment. If we define our system to include the environment, then the mass of the system remains constant. Basically, mass cannot appear from nowhere and does not disappear without a trace. Imagine you have a system that has a total mass of $m_i = 3\text{ kg}$ (say, a bag of oranges). In the environment (your refrigerator), you have another kilogram of oranges. You add these oranges to the bag ($\Delta m = 1\text{ kg}$). The final mass of the system equals exactly the sum of the initial mass and the added mass: $m_i + \Delta m = m_f$, or $3\text{ kg} + 1\text{ kg} = 4\text{ kg}$. Notice that the total mass of the oranges in the system and the environment did not



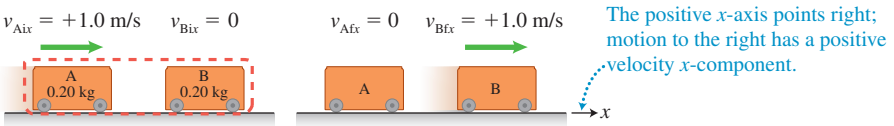
change (**Figure 6.2a**). We can represent this process with a *bar chart* (Figure 6.2b). The bar on the left represents the initial mass of the system, the central bar represents the mass added or taken away, and the bar on the right represents the mass of the system in the final situation. As a result, the height of the left bar plus the height of the central bar equals the height of the right bar. The bar chart allows us to keep track of the changes in mass of a system even if the system is not isolated.

Conserved quantities Mass is an example of a **conserved** quantity. A conserved quantity is constant in an isolated system. When the system is not isolated, the quantity may change. However, if it does, we can always find another system in which the quantity is constant.

Just as with every idea in physics, the law of constancy of mass in an isolated system does not apply in all cases. We will discover later in this book (Chapters 29 and 30) that in situations involving atomic particles, mass is not constant even in an isolated system; instead, what is constant is a new quantity that includes mass as a component.

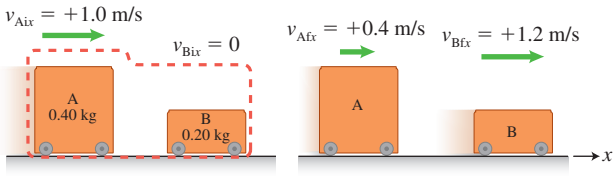
REVIEW QUESTION 6.1 When you burn a log in a fire pit, the mass of wood clearly decreases. How can you define the system so that the mass of the objects in that system remains constant?

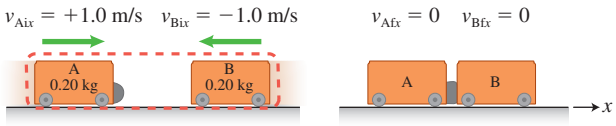
FIGURE 6.2 (a) The initial mass of the oranges plus the mass of the oranges that were added (or subtracted) equals the final mass of the oranges. (b) The mass change process is represented by a mass bar chart.



6.2 Linear momentum

We now know that mass is an example of a conserved quantity. Is there a quantity related to motion that is conserved? When you kick a stationary ball, there seems to be a transfer of motion from your foot to the ball. When you knock bowling pins down with a bowling ball, a similar transfer occurs. However, motion is not a physical quantity. What physical quantities describing motion are constant in an isolated system? Can we describe the changes in these quantities using a bar chart?





Let's conduct a few experiments to find out. In Observational Experiment **Table 6.1** we observe two carts of different masses that collide on a smooth track. For these experiments, the system will include both carts. A *collision* is a process that occurs when two (or more) objects come into direct contact with each other. The system is isolated since the forces that the carts exert on each other are internal, and external forces either add to zero (as do the vertical forces) or are negligible (the horizontal friction force).

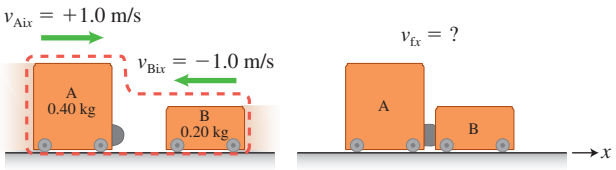
OBSERVATIONAL EXPERIMENT TABLE 6.1 Collisions in a system of two carts

VIDEO OET 6.1

Observational experiment	Analysis
Experiment 1. Cart A (0.20 kg) moving right at 1.0 m/s collides with cart B (0.20 kg), which is stationary. Cart A stops, and cart B moves right at 1.0 m/s.	 • *Speed:* The sum of the speeds of the objects is the same before and after the collision: $1.0\ \text{m/s} + 0\ \text{m/s} = 0\ \text{m/s} + 1.0\ \text{m/s}$. • *Mass · speed:* The sum of the products of mass and speed is the same before and after the collision: $0.20\ \text{kg}(1.0\ \text{m/s}) + 0.20\ \text{kg}(0\ \text{m/s}) = 0.20\ \text{kg}(0\ \text{m/s}) + 0.20\ \text{kg}(1.0\ \text{m/s})$. • *Mass · velocity:* The sum of the products of mass and the x-component of velocity is the same before and after the collision: $0.20\ \text{kg}(+1.0\ \text{m/s}) + 0.20\ \text{kg}(0) = 0.20\ \text{kg}(0) + 0.20\ \text{kg}(+1.0\ \text{m/s})$.

(CONTINUED)

Observational experiment	Analysis
Experiment 2. Cart A (0.40 kg) moving right at 1.0 m/s collides with cart B (0.20 kg), which is stationary. After the collision, both carts move right, cart B at 1.2 m/s and cart A at 0.4 m/s.	 • *Speed:* The sum of the speeds of the objects is not the same before and after the collision: $1.0\ \text{m/s} + 0\ \text{m/s} \neq 0.4\ \text{m/s} + 1.2\ \text{m/s}$. • *Mass · speed:* The sum of the products of mass and speed is the same before and after the collision: $0.40\ \text{kg}(1.0\ \text{m/s}) + 0.20\ \text{kg}(0\ \text{m/s}) = 0.40\ \text{kg}(0.4\ \text{m/s}) + 0.20\ \text{kg}(1.2\ \text{m/s})$. • *Mass · velocity:* The sum of the products of mass and the x-component of velocity is the same before and after the collision: $0.40\ \text{kg}(+1.0\ \text{m/s}) + 0.20\ \text{kg}(0) = 0.40\ \text{kg}(+0.4\ \text{m/s}) + 0.20\ \text{kg}(+1.2\ \text{m/s})$.
Experiment 3. Cart A (0.20 kg) with a piece of clay attached to the front moves right at 1.0 m/s. Cart B (0.20 kg) moves left at 1.0 m/s. The carts collide, stick together, and stop.	 • *Speed:* The sum of the speeds of the objects is not the same before and after the collision: $1.0\ \text{m/s} + 1.0\ \text{m/s} \neq 0\ \text{m/s} + 0\ \text{m/s}$. • *Mass · speed:* The sum of the products of mass and speed is not the same before and after the collision: $0.20\ \text{kg}(1.0\ \text{m/s}) + 0.20\ \text{kg}(1.0\ \text{m/s}) \neq 0.20\ \text{kg}(0\ \text{m/s}) + 0.20\ \text{kg}(0\ \text{m/s})$. • *Mass · velocity:* The sum of the products of mass and the x-component of velocity is the same before and after the collision: $0.20\ \text{kg}(+1.0\ \text{m/s}) + 0.20\ \text{kg}(-1.0\ \text{m/s}) = 0.20\ \text{kg}(0\ \text{m/s}) + 0.20\ \text{kg}(0\ \text{m/s})$.



Pattern

One quantity remains the same before and after the collision in each experiment—the sum of the products of the mass and the x-velocity component of the objects.

In the three experiments in Table 6.1, only one quantity—the sum of the products of the mass and the x-component of velocity, $\Sigma m v_x$—remained the same before and after the carts collided. Note also that the sum of the products of the mass and the y-component of velocity, $\Sigma m v_y$, did not change—it remained zero. Perhaps $\Sigma m\vec{v}$ is the quantity characterizing some quantity of motion that is constant in an isolated system. But will this pattern persist in other situations? Let's test this idea by using it to predict the outcome of the experiment in Testing Experiment Table 6.2.

TESTING EXPERIMENT TABLE 6.2 Testing the idea that $\Sigma m\vec{v}$ in an isolated system remains constant

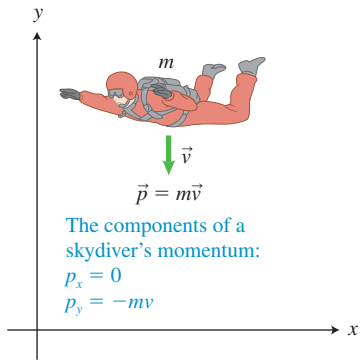
VIDEO TET 6.2

Testing experiment	Prediction	Outcome
Cart A (0.40 kg) has a piece of modeling clay attached to its front and is moving right at 1.0 m/s. Cart B (0.20 kg) is moving left at 1.0 m/s. The carts collide and stick together. Predict the velocity of the carts after the collision.	 The system consists of the two carts. The direction of velocity is noted with a plus or minus sign of the velocity component: $(0.40\ \text{kg})(+1.0\ \text{m/s}) + (0.20\ \text{kg})(-1.0\ \text{m/s}) = (0.40\ \text{kg} + 0.20\ \text{kg})v_{fx}$ or $v_{fx} = (+0.20\ \text{kg}\cdot\text{m/s})/(0.60\ \text{kg}) = +0.33\ \text{m/s}$ After the collision, the two carts should move right at a speed of about 0.33 m/s.	After the collision, the carts move together toward the right at close to the predicted speed.

Conclusion

Our prediction matched the outcome. The quantity $m\vec{v}$ might be the quantity whose sum is constant in an isolated system.

This new quantity is called **linear momentum** $\vec{p}$.



Linear momentum The linear momentum $\vec{p}$ of a single object is the product of its mass m and velocity $\vec{v}$:

$$\vec{p} = m\vec{v} \tag{6.1}$$

Linear momentum is a vector quantity that points in the same direction as the object's velocity $\vec{v}$ (**Figure 6.3**). The SI unit of linear momentum is $(\text{kg} \cdot \text{m/s})$. The total linear momentum of a system containing multiple objects is the vector sum of the momenta (plural of momentum) of the individual objects.

$$\vec{p}_{\text{net}} = m_1\vec{v}_1 + m_2\vec{v}_2 + \cdots + m_n\vec{v}_n = \Sigma m\vec{v}$$

FIGURE 6.3 Momentum is a vector quantity with components.

Note the following three important points.

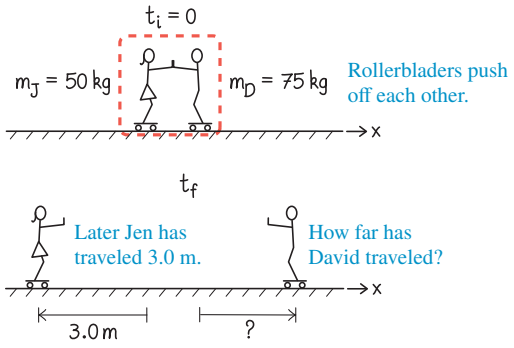
1. Unlike mass, which is a scalar quantity, $\vec{p} = m\vec{v}$ is a vector quantity. Therefore, it is important to consider the direction in which the colliding objects are moving before and after the collision. For example, because cart B in Table 6.2 was moving left along the x-axis, the x-component of its momentum was negative before the collision.
2. Because momentum depends on the velocity of the object, and the velocity depends on the choice of the reference frame, different observers will measure different momenta for the same object. As a passenger, the momentum of a car with respect to you is zero. However, it is not zero for an observer on the ground watching the car move away from him.
3. We chose an isolated system (the two carts) for our investigation. The sum of the products of mass and velocity $\Sigma m\vec{v}$ of all objects in the isolated system remained constant even though the carts collided with each other. However, if we had chosen the system to be just one of the carts, we would see that the linear momentum $\vec{p} = m\vec{v}$ of the cart before the collision differs from that after the collision. Thus, to establish that momentum $\vec{p}$ is a conserved quantity, we need to make sure that when the momentum of a chosen system changes, we can find a new system in which momentum is constant.

Momentum constancy of an isolated system The momentum of an isolated system is constant. For an isolated two-object system:

$$m_1\vec{v}_{1\text{i}} + m_2\vec{v}_{2\text{i}} = m_1\vec{v}_{1\text{f}} + m_2\vec{v}_{2\text{f}} \tag{6.2}$$

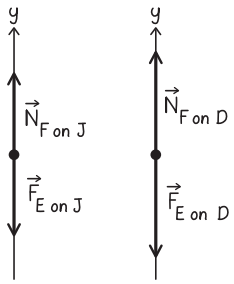
Because momentum is a vector quantity and Eq. (6.2) is a vector equation, we will work with its x- and y-component forms:

$$m_1v_{1\text{i}x} + m_2v_{2\text{i}x} = m_1v_{1\text{f}x} + m_2v_{2\text{f}x} \tag{6.3x}$$



$$m_1v_{1\text{i}y} + m_2v_{2\text{i}y} = m_1v_{1\text{f}y} + m_2v_{2\text{f}y} \tag{6.3y}$$

For a system with more than two objects, we simply include a term on each side of the equation for each object in the system. Let's test the idea that the momentum of an isolated system is constant in another situation.



EXAMPLE 6.1 Two Rollerbladers

Jen (50 kg) and David (75 kg), both on Rollerblades, push off each other abruptly. Each person coasts backward at approximately constant speed. During a certain time interval, Jen travels 3.0 m. How far does David travel during that same time interval?

Sketch and translate The process is sketched below. All motion is with respect to the floor and is along the x-axis. We choose the two Rollerbladers as the system. Initially, they are at rest. After pushing off, Jen (J) moves to the left and David (D) moves to the right. We can use momentum constancy to calculate David's velocity component and predict the distance he will travel during that same time interval.

Simplify and diagram We model each person as a point-like object and assume that the friction force exerted on the Rollerbladers does not affect their motion. Thus there are no horizontal external forces exerted on the system. In addition, the two vertical forces, an upward normal force $\vec{N}_{\text{F on P}}$ that the floor exerts on each person and an equal-magnitude downward gravitational force $\vec{F}_{\text{E on P}}$ that Earth exerts on each person, cancel, as we see in the force diagrams. Since the net external force exerted on the system is zero, the system is isolated. The forces that the Rollerbladers exert on each other are internal forces and should not affect the momentum of the system.

Represent mathematically The initial state (i) of the system is before they start pushing on each other, and the final state (f) is when Jen has traveled 3.0 m.

$$m_J v_{Jix} + m_D v_{Dix} = m_J v_{Jfx} + m_D v_{Dfx}$$

We choose the positive direction toward the right. Because the initial velocity of each person is zero, the above equation becomes

$$0 + 0 = m_J v_{Jfx} + m_D v_{Dfx}$$

or

$$m_D v_{Dfx} = -m_J v_{Jfx}$$

Solve and evaluate The x-component of Jen's velocity after the push is $v_{Jfx} = -(3.0\text{ m})/\Delta t$, where Δt is the time interval needed for her to travel 3.0 m. We solve the above equation for David's final x-velocity component to determine how far David should travel during that same time interval:

$$v_{Dfx} = -\frac{m_J v_{Jfx}}{m_D} = -\frac{m_J}{m_D} v_{Jfx} = -\frac{(50\text{ kg})}{(75\text{ kg})}\frac{(-3.0\text{ m})}{\Delta t} = \frac{(2.0\text{ m})}{\Delta t}$$

If momentum is constant in this isolated system, then David should travel 2.0 m in the positive direction during Δt. The measured value is very close to the predicted value.

Try it yourself Estimate the magnitude of your momentum when walking and when jogging. Assume your mass is 60 kg.

Answer When walking, you travel at a speed of about 1 to 2 m/s. So the magnitude of your momentum will be $p = mv \approx (60\text{ kg})(1.5\text{ m/s}) \approx 90\text{ kg}\cdot\text{m/s}$. When jogging, your speed is about 2 to 5 m/s or a momentum of magnitude $p = mv \approx (60\text{ kg})(3.5\text{ m/s}) \approx 200\text{ kg}\cdot\text{m/s}$.

Notice that in Example 6.1 we were able to determine David's velocity by using the principle of momentum constancy. We did not need any information about the forces involved. This is a very powerful result, since in all likelihood the forces they exerted on each other were not constant. The kinematics equations we have used up to this point have assumed constant acceleration of the system (and thus constant forces). Using the idea of momentum constancy has allowed us to analyze a situation involving nonconstant forces.

So far, we have investigated situations involving isolated systems. In the next section, we will investigate momentum in nonisolated systems.

REVIEW QUESTION 6.2 Ryan says, "Based on the experiments in Table 6.1, momentum of an isolated system during some collisions can disappear." What information in the table prompted Ryan to make this statement? Is Ryan correct? Explain your answer.

6.3 Impulse and momentum

So far, we have found that the linear momentum of a system is constant if that system is isolated (the net external force exerted on the system is zero). In this section, we will learn how to use Newton's laws to account for the changes in momentum when the system is not isolated.

Impulse due to a force exerted on a single object

When you push a bowling ball, you exert a force on it, causing the ball to accelerate. The average acceleration $\vec{a}$ is defined as the change in velocity $\vec{v}_f - \vec{v}_i$ divided by the time interval $\Delta t = t_f - t_i$ during which that change occurs:

$$\vec{a} = \frac{\vec{v}_f - \vec{v}_i}{t_f - t_i}$$

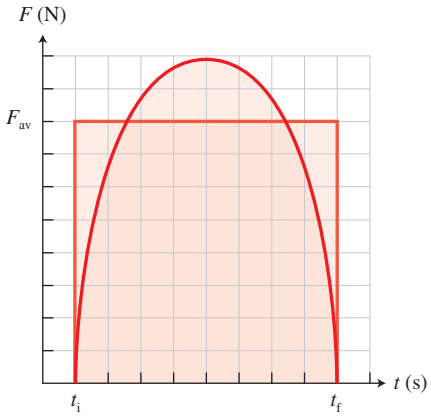
We can also use Newton's second law to determine an object's acceleration if we know its mass and the sum of the forces that other objects exert on it:

$$\vec{a} = \frac{\Sigma \vec{F}}{m}$$

We now have two expressions for an object's acceleration. Setting these two expressions for acceleration equal to each other, we get

$$\frac{\vec{v}_f - \vec{v}_i}{t_f - t_i} = \frac{\Sigma \vec{F}}{m}$$

Now multiply both sides by $m(t_f - t_i)$ and get the following:



$$m\vec{v}_f - m\vec{v}_i = \vec{p}_f - \vec{p}_i = \Sigma \vec{F}(t_f - t_i) \tag{6.4}$$

The left side of this equation is the change in momentum of the object. This change depends on the product of the sum of the external forces and the time interval during which the forces are exerted on the object (the right side of the equation). Note these two important points:

1. Equation (6.4) is just Newton's second law written in a different form—one that involves the physical quantity momentum. It assumes that the sum of the forces does not change during the time interval. Actually, Newton wrote the second law using momentum notation, not masses and acceleration, so historically Eq. (6.4) is Newton's second law.
2. The forces *and* time interval affect momentum—the longer the time interval, the greater the momentum change. A small force exerted for a long time interval can change the momentum of an object by the same amount as a large force exerted for a short time interval.

The product of any external force exerted on an object during a time interval and the time interval gives us a new quantity, the **impulse** of that force. When you kick a football or hit a baseball with a bat, your foot or the bat exerts an impulse on the ball. The forces in these situations are not constant but instead vary in time (see the example in **Figure 6.4**). The shaded area under the varying force curve represents the impulse of the force. We can estimate the impulse by drawing a horizontal line that is approximately the average force exerted during the time interval of the impulse. The area under the rectangular average force-impulse curve equals the product of the height of the rectangle (the average force) and the width of the rectangle (the time interval over which the average force is exerted). The product $F_{av}(t_f - t_i)$ equals the magnitude of the impulse.

FIGURE 6.4 The impulse of a force is the area under the F-versus-t graph line.

The area of the shaded rectangle is about the same as the area under the curved line and equals the impulse of the force.

Impulse The impulse $\vec{J}$ of a force is the product of the average force $\vec{F}_{av}$ exerted on an object during a time interval $(t_f - t_i)$ and that time interval:

$$\vec{J} = \vec{F}_{av}(t_f - t_i) \tag{6.5}$$

Impulse is a vector quantity that points in the direction of the force. The impulse has a plus or minus sign depending on the orientation of the force relative to a coordinate axis. The SI unit for impulse is $N \cdot s = (kg \cdot m/s^2) \cdot s = kg \cdot m/s$, the same unit as momentum.

It is often difficult to measure directly the impulse of the average of the sum of the forces during a time interval. However, we can determine the average of the sum of the forces on the right side of Eq. (6.4) indirectly by measuring or calculating the momentum change on the left side of the equation. For this reason, the combination of impulse and momentum change provides a powerful tool for analyzing interactions between objects. We can now write Eq. (6.4) as the **impulse-momentum equation** for a single object.

Impulse-momentum equation for a single object If several external objects exert forces on a single-object system during a time interval $(t_f - t_i)$, the sum of their impulses $\Sigma\vec{J}$ causes a change in momentum of the system:

$$\vec{p}_f - \vec{p}_i = \Sigma\vec{J} = \Sigma\vec{F}_{\text{on System}}(t_f - t_i) \tag{6.6}$$

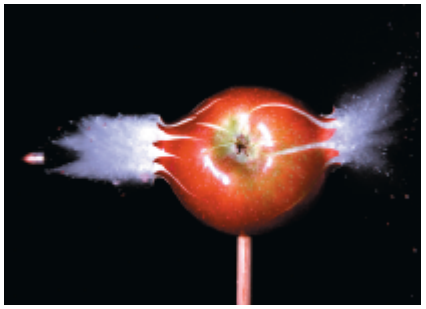
The x- and y-scalar component forms of the impulse-momentum equation are

$$p_{fx} - p_{ix} = \Sigma F_{\text{on System}\,x}(t_f - t_i) \tag{6.7x}$$

$$p_{fy} - p_{iy} = \Sigma F_{\text{on System}\,y}(t_f - t_i) \tag{6.7y}$$

A few points are worth emphasizing. First, notice that Eq. (6.6) is a vector equation, as both the momentum and the impulse are vector quantities. Vector equations are not easy to manipulate mathematically. Therefore, we will use the scalar component forms of Eq. (6.6)—Eqs. (6.7x) and (6.7y).

Second, the time interval in the impulse-momentum equation is very important. When object 2 exerts a force on object 1, the momentum of object 1 changes by an amount equal to



$$\Delta\vec{p}_1 = \vec{p}_{1f} - \vec{p}_{1i} = \vec{F}_{2\text{ on }1}(t_f - t_i) = \vec{F}_{2\text{ on }1}\Delta t$$

The longer that object 2 exerts this force on object 1, the greater the momentum change of object 1. This explains why a fast-moving object might have a smaller effect on a stationary object during a collision than a slow-moving object interacting with the stationary object over a longer time interval. For example, a fast-moving bullet passing through a partially closed wooden door might not open the door (it will just make a hole in the door), whereas your little finger, moving much slower than the bullet, could open the door. Although the bullet moves at high speed and exerts a large force on the door, the time interval during which it interacts with the door is very small (milliseconds). Hence, it exerts a relatively small impulse on the door—too small to significantly change the door's momentum. A photo of a bullet shot through an apple illustrates the effect of a short impulse time (**Figure 6.5**). The impulse exerted by the bullet on the apple was too small to knock the apple off its support.

Third, if the magnitude of the force changes during the time interval considered in the process, we use the average force.

Finally, if the same amount of force is exerted for the same time interval on a large-mass object and on a small-mass object, the objects will have an equal change in momentum (the same impulse was exerted on them). However, the small-mass object will experience a greater change in velocity than the large-mass object.

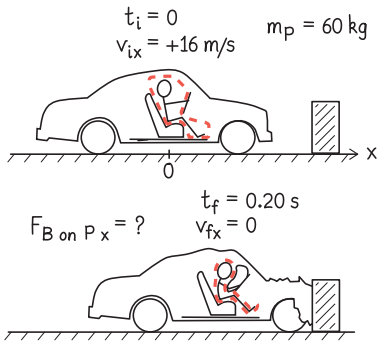


FIGURE 6.5 When a bullet is shot through an apple balanced on a support, the bullet's time of interaction with the apple is very short, causing a small impulse that does not knock the apple over.

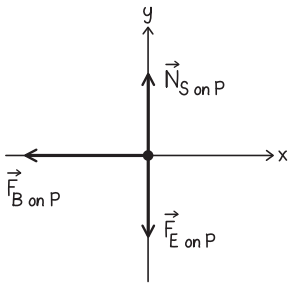


EXAMPLE 6.2 **Abrupt stop in a car**

A 60-kg person is traveling in a car that is moving at 16 m/s with respect to the ground when the car hits a barrier. The person is not wearing a seat belt, but is stopped by an air bag in a time interval of 0.20 s. Determine the *average* force that the air bag exerts on the person while stopping him.

Sketch and translate First we draw an initial-final sketch of the process. We choose the person as the system since we are investigating a force being exerted on him.

Simplify and diagram The force diagram shows the average force $\vec{F}_{\text{B on P}}$ exerted in the negative direction by the bag on the person. The vertical forces exerted by Earth and the seat on the person add to zero.

Represent mathematically The x-component form of the impulse-momentum equation is

$$m_P v_{Pix} + F_{B\text{ on P}\,x}(t_f - t_i) = m_P v_{Pfx}$$

Solve and evaluate Solve for the force exerted by the air bag on the person:

$$F_{B\text{ on P}\,x} = \frac{m_P(v_{Pfx} - v_{Pix})}{(t_f - t_i)}$$

The person's initial x-component of velocity $v_{Pix} = +16$ m/s decreases to the final x-component of velocity $v_{Pfx} = 0$ in a time interval $(t_f - t_i) = 0.20$ s. Thus the average force exerted by the air bag on the person in the x-direction is

$$F_{B\text{ on P}\,x} = \frac{(60\text{ kg})(0 - 16\text{ m/s})}{(0.20\text{ s} - 0)} = -4800\text{ N}$$

The negative sign in −4800 N indicates that the average force points in the negative x-direction. The magnitude of this force is about 1000 lb!

Try it yourself Suppose a 60-kg crash test dummy is in a car traveling at 16 m/s. The dummy is not wearing a seat belt and the car has no air bags. During a collision, the dummy flies forward and stops when it hits the dashboard. The stopping time interval for the dummy is 0.02 s. What is the average magnitude of the stopping force that the dashboard exerts on the dummy?

Answer The average force that the hard surface exerts on the dummy is about 50,000 N, extremely unsafe for a human. Note that the momentum change of the person in Example 6.2 was the same. However, since the change for the dummy occurs during a shorter time interval (0.02 s instead of 0.20 s), the force exerted on the dummy is much greater. This is why air bags save lives.

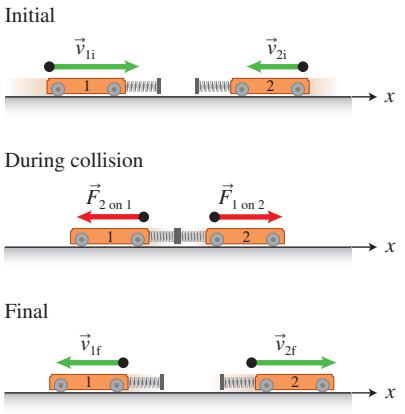
Newton's laws and momentum constancy

Let's apply the impulse-momentum equation Eq. (6.6) to the scenario we described in Table 6.1 in order to explore momentum constancy in a two-object isolated system.

Two carts travel toward each other at different speeds, collide, and rebound (**Figure 6.6**). We first analyze each cart as a separate system and then analyze them together as a single system. Assume that the vertical forces exerted on the carts add to zero and that the friction force exerted by the surface on the carts does not significantly affect their motion.

Cart 1: In the initial state, before the collision, cart 1 with mass m_1 travels in the positive direction at velocity $\vec{v}_{1i}$. In the final state, after the collision, cart 1 moves with a different velocity $\vec{v}_{1f}$ in the opposite direction. To determine the effect of the impulse exerted by cart 2 on cart 1, we apply the impulse-momentum equation to cart 1 only:

$$m_1(\vec{v}_{1f} - \vec{v}_{1i}) = \vec{F}_{2\text{ on }1}(t_f - t_i)$$



Cart 2: We repeat this analysis with cart 2 as the system. Its velocity and momentum change because of the impulse exerted on it by cart 1:

$$m_2(\vec{v}_{2f} - \vec{v}_{2i}) = \vec{F}_{1\text{ on }2}(t_f - t_i)$$

Newton's third law provides a connection between our analyses of the two carts; interacting objects at each instant exert equal-magnitude but oppositely directed forces on each other:

$$\vec{F}_{1\text{ on }2} = -\vec{F}_{2\text{ on }1}$$

FIGURE 6.6 Analyzing the collision of two carts in order to develop the momentum constancy idea.

Substituting the expressions for the forces from above and simplifying, we get

$$\frac{m_2(\vec{v}_{2f} - \vec{v}_{2i})}{t_f - t_i} = -\frac{m_1(\vec{v}_{1f} - \vec{v}_{1i})}{t_f - t_i}$$

Next, we multiply both sides by the time interval.

$$m_2(\vec{v}_{2f} - \vec{v}_{2i}) = -m_1(\vec{v}_{1f} - \vec{v}_{1i})$$

We now move the initial momentum for both objects to the left side and the final momentum for both objects to the right side, making sure we keep track of the signs:

$$\underset{\text{Initial momentum}}{m_1\vec{v}_{1i} + m_2\vec{v}_{2i}} = \underset{\text{Final momentum}}{m_1\vec{v}_{1f} + m_2\vec{v}_{2f}}$$

This is Eq. (6.2), the equation we arrived at in Section 6.2, where we observed and analyzed collisions to understand the constant momentum of an isolated system. Here we have reached the same conclusions using only our knowledge of Newton's laws, momentum, and impulse. What is really important here is that while the momentum of each cart changes during the collision, if we choose the system to comprise both carts, the momentum of that system stays constant. We also see that the internal forces (in this case, the forces that carts exert on each other) cannot change the momentum of the system.

REVIEW QUESTION 6.3 An apple is falling from a tree. Why does its momentum change? Specify the external force responsible. Find a system in which the momentum is constant during this process.

6.4 The generalized impulse-momentum principle

TIP It is important to understand the difference between *conservation* and *constancy*. Mass and momentum are conserved quantities, but they are not necessarily constant in a particular system. When two carts of different masses collide, during the instant of collision, the momentum of each cart as a system changes by the amount of impulse exerted on it by the other cart (momentum is not constant). However, in the system that includes both carts, the momentum is constant. When the momentum of each cart changed, it did not disappear. It appeared in the addition to the momentum of the second cart (momentum is conserved).

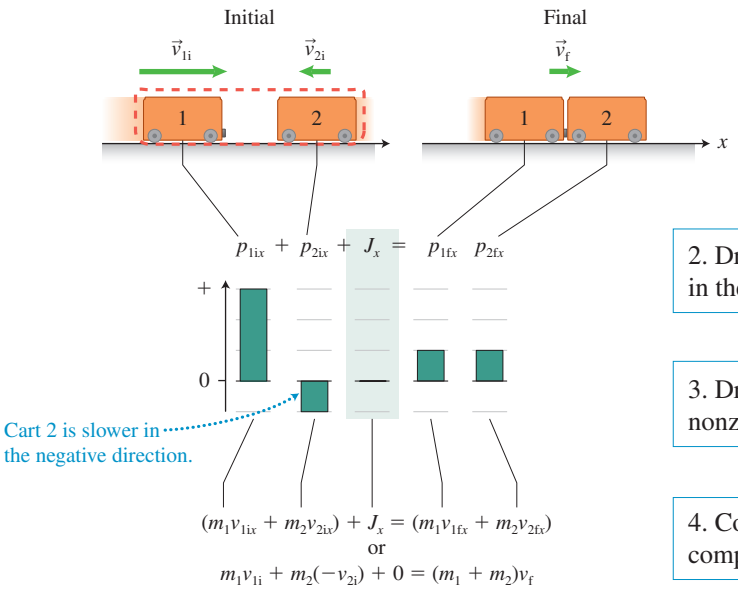
Let's summarize what we have learned about momentum. The change in momentum of a system is equal to the net external impulse exerted on it. If the net impulse is zero, then the momentum of the system is constant. If the objects outside the system exert forces on it and change its momentum, we can always redefine the system by including all interacting objects to keep the momentum of this new system constant. Therefore, **momentum is a conserved quantity.** This idea, expressed mathematically as the **generalized impulse-momentum principle**, accounts for situations in which the system includes one or more objects and may or may not be isolated.

Generalized impulse-momentum principle For a system containing one or more objects, the initial momentum of the system plus the sum of the impulses that external objects exert on the system during the time interval $(t_f - t_i)$ equals the final momentum of the system:

$$\underset{\substack{\text{Initial momentum of}\\ \text{the system}}}{(m_1\vec{v}_{1i} + m_2\vec{v}_{2i} + \cdots)} + \underset{\substack{\text{Net impulse exerted on}\\ \text{the system}}}{\Sigma\vec{F}_{\text{on Sys}}(t_f - t_i)} = \underset{\substack{\text{Final momentum of}\\ \text{the system}}}{(m_1\vec{v}_{1f} + m_2\vec{v}_{2f} + \cdots)} \qquad (6.8)$$

The x- and y-component forms of the generalized impulse-momentum principle are

$$(m_1v_{1ix} + m_2v_{2ix} + \cdots) + \Sigma F_{\text{on Sys}\,x}(t_f - t_i) = (m_1v_{1fx} + m_2v_{2fx} + \cdots) \qquad (6.9x)$$



$$(m_1v_{1iy} + m_2v_{2iy} + \cdots) + \Sigma F_{\text{on Sys}\,y}(t_f - t_i) = (m_1v_{1fy} + m_2v_{2fy} + \cdots) \qquad (6.9y)$$

Note: If the net impulse exerted in a particular direction is zero, then the component of the momentum of the system in that direction is constant.

Impulse-momentum bar charts

We can describe an impulse-momentum process mathematically using Eqs. (6.9x and y). These equations help us see that we can represent the changes of a system's momentum using a bar chart similar to the one used to represent the changes of a system's mass. Physics Tool Box 6.1 shows the steps for constructing an **impulse-momentum bar chart** for a simple system of two carts of equal mass traveling toward each other.

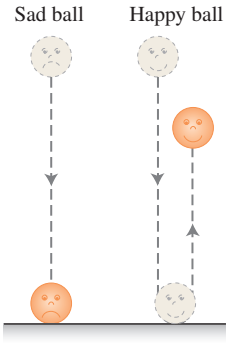
PHYSICS TOOL BOX 6.1 **Constructing a qualitative impulse-momentum bar chart**

1. Sketch the process, choose the initial and final states, and choose a system.

2. Draw initial and final momentum bars for each object in the system. (Note cart directions and bar directions.)

3. Draw an impulse (J) bar if there is an external nonzero impulse.

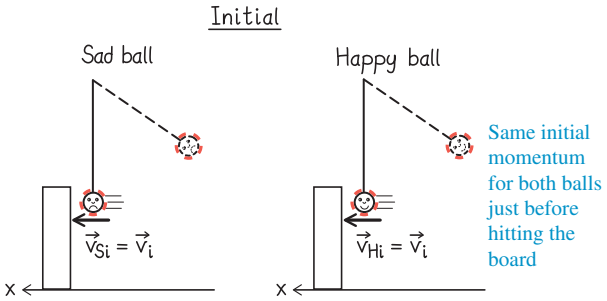
4. Convert each bar in the chart into a term in the component form of the impulse-momentum principle.



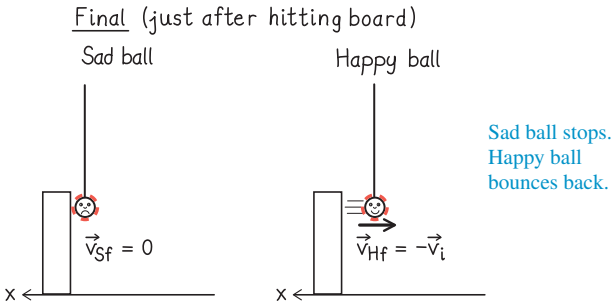
Note that before constructing the bar chart, we represent the process in an initial-final sketch (Step 1 in the Tool Box). We then use the sketch to help construct the impulse-momentum bar chart. The lengths of the bars are *qualitative* indicators of the relative magnitudes of the momenta. In the final state in the example shown, the carts are stuck together and are moving in the positive direction. Since they have the same mass and velocity, they each have the same final momentum.

The middle shaded column in the bar chart represents the net external impulse exerted on the system during the time interval $(t_f - t_i)$—there is no impulse for the process shown. The shading reminds us that impulse does not reside in the system; it is the influence of the external objects on the momentum of the system. In our choice of the system, there is no bar in this column because the system is isolated. But if we choose only one cart as the system, then the influence of the second cart will be represented with a bar in the impulse column of the bar chart. Notice that the sum of the heights of the bars on the left plus the height of the shaded impulse bar should equal the sum of the heights of the bars on the right. This "conservation of bar heights" reflects the conservation of momentum.

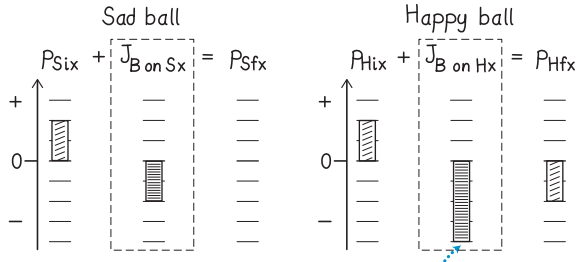
We can use the bar chart to apply the generalized impulse-momentum principle (Step 4). Each nonzero bar corresponds to a nonzero term in the equation; the sign of the term depends on the orientation of the bar.



TIP When you draw a bar chart, always specify the reference frame (the object of reference and the coordinate system). The direction of the bars on the bar chart (up for positive and down for negative) should match the direction of the momentum or impulse based on the chosen coordinate system.



EXAMPLE 6.3 Happy and sad balls



You have two balls of identical mass and size that behave very differently. When you drop the so-called "sad" ball, it thuds on the floor and does not bounce at all. When you drop the so-called "happy" ball from the same height, it bounces back to almost the same height from which it was dropped. The difference in the bouncing ability of the happy ball is due to its internal structure; it is made of different material. You hang each ball from a string of identical length and place a wood board on its end so that the top of the board is next to the hanging ball, and if you pull the ball back and release it, it hits the top of the board. You pull each ball back to an equal height and release the balls one at a time. Which has the best chance of knocking the board over: the sad ball or the happy ball?

Sketch and translate Initial and final sketches of the process are shown below. The system is just the ball. In the initial state, the ball is just about to hit the board, moving horizontally toward the left (the balls are moving equally fast). The final state is just after the collision with the board. The happy ball (H) bounces back, whereas the sad ball (S) does not.

Simplify and diagram Assume that the collision time interval Δt for each ball is about the same. We analyze only the horizontal x-component of the process, the component that is relevant to whether or not each of the boards is knocked over. Each board exerts an impulse on the ball that causes the momentum of the ball to change. Therefore, each ball, according to Newton's third law, exerts an impulse on the board that it hits. A larger force exerted on the board means a larger impulse and a better chance to tip the board. A bar chart for each ball-board collision is shown below.

The impulse exerted by the board on the ball during the collision is equal in magnitude to the impulse that the ball exerts on the board. Thus, based on the bar charts the impulse exerted by the happy ball on the board is twice as large in magnitude as that of the sad ball and causes twice as large a momentum change.

Represent mathematically The x-component form of the impulse-momentum Eq. (6.9x) applied to each ball is as follows:

Sad ball: $$mv_i + F_{B\ on\ S\,x}\Delta t = m \cdot 0$$

Happy ball: $$mv_i + F_{B\ on\ H\,x}\Delta t = m(-v_i)$$

Note that the x-component of the final velocity of the sad ball is $v_{Sfx} = 0$ (it does not bounce) and that the x-component of the final velocity of the happy ball is $v_{Hfx} = -v_i$ (it bounces).

Solve and evaluate We can now get an expression for the force exerted by each board on each ball:

Sad ball: $$F_{B\ on\ S\,x} = \frac{m(0 - v_i)}{\Delta t} = -\frac{mv_i}{\Delta t}$$

Happy ball: $$F_{B\ on\ H\,x} = \frac{m[\,(-v_i) - v_i\,]}{\Delta t} = -\frac{2mv_i}{\Delta t}$$

Because we assumed that the time of collision is the same, the board exerts twice the force on the happy ball as on the sad ball, since the board causes the happy ball's momentum to change by an amount twice that of the sad ball. According to Newton's third law, this means that the happy ball exerts twice as large a force on the board as the sad ball. Thus, the happy ball has a greater chance of tipping the board.

VIDEO 6.1

Try it yourself Is it less safe for a football player to bounce backward off a goal post or to hit the goal post and stop?

Answer Although any collision is dangerous, it is better to hit the goal post and stop. If the football player bounces back off the goal post, his momentum will have changed by a greater amount (like the happy ball in this example). This means that the goal post exerts a greater force on him, which means there is a greater chance for injury.

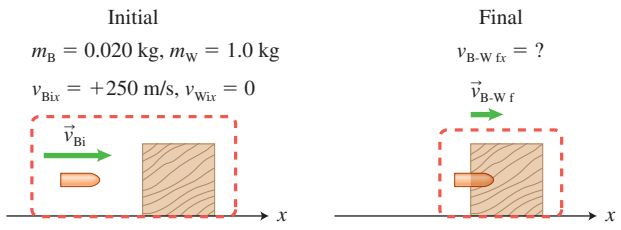
The pattern we found in the example above is true for all collisions—when an object bounces back after a collision, we know that a larger magnitude force is exerted on it than if the object had stopped and did not bounce after the collision. For that reason, bulletproof vests for law enforcement agents are designed so that the bullet embeds in the vest rather than bouncing off it.

REVIEW QUESTION 6.4 If in solving the problem in Example 6.3 we chose the system to be the ball and the board, how would the mathematical description for each ball-board collision change?

6.5 Skills for analyzing problems using impulse and momentum

Initial and final sketches and bar charts are useful tools to help analyze processes using the impulse-momentum principle. Let's investigate further how these tools work together. A general strategy for analyzing such processes is described on the left side of the table in Example 6.4 and illustrated on the right side for a specific process.

PROBLEM-SOLVING STRATEGY 6.1 Applying the generalized impulse-momentum principle



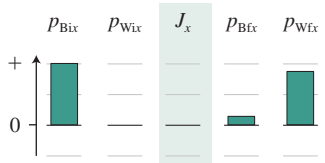
Sketch and translate

- Sketch the initial and final states and include appropriate coordinate axes. Label the sketches with the known information and identify the unknowns. Decide on the object of reference.
- Choose a system based on the quantity you are interested in, for example, a multi-object isolated system to determine the velocity of an object, or a single-object nonisolated system to determine an impulse or force. Sometimes it is better to decide what is in your system and then identify initial and final states.

EXAMPLE 6.4 Bullet hits wood block

A 0.020-kg bullet traveling horizontally at 250 m/s embeds in a 1.0-kg block of wood resting on a table. Determine the speed of the bullet and wood block together immediately after the bullet embeds in the block.

The left side of the sketch below shows the bullet traveling in the positive x-direction with respect to the ground; it then joins the wood. All motion is along the x-axis; the object of reference is Earth. The system includes the bullet and wood; it is an isolated system since the vertical forces balance. The initial state is immediately before the collision; the final state is immediately after.



(CONTINUED)

Simplify and diagram

- Determine if there are any external impulses exerted on the system. Drawing a force diagram could help determine the external forces and their directions.
- Draw an impulse-momentum bar chart for the system for the chosen direction(s) to help you understand the situation, formulate a mathematical representation of the process, and evaluate your results.

Assume that the friction force exerted by the tabletop on the bottom of the wood does not change the momentum of the system during the very short collision time interval. The bar chart represents the process. The bar for the bullet is shorter than that for the block—their velocities are the same after the collision, but the mass of the bullet is much smaller. We do not draw a force diagram here, as the system is isolated.

Represent mathematically

- Use the bar chart to apply the generalized impulse-momentum principle along the chosen axis. Each nonzero bar becomes a nonzero term in the equation. The orientation of the bar determines the sign in front of the corresponding term in the final equation.
- Remember that momentum and impulse are vector quantities, so include the plus or minus signs of the components based on the chosen coordinate system.

$$m_B v_{Bix} + m_W \cdot 0 + (J_x) = m_B v_{B\text{-}Wfx} + m_W v_{B\text{-}Wfx}$$

Since $J_x = 0$,

$$v_{B\text{-}Wfx} = \frac{m_B v_{Bix}}{(m_B + m_W)}$$

Solve and evaluate

- Insert the known information to determine the unknown quantity.
- Check if your answer is reasonable with respect to sign, unit, and magnitude. Also make sure it applies for limiting cases, such as objects of very small or very large mass.

$$v_{B\text{-}Wfx} = \frac{(0.020\ \text{kg})(250\ \text{m/s})}{(0.020\ \text{kg} + 1.0\ \text{kg})} = +4.9\ \text{m/s}$$

The magnitude of the answer seems reasonable given how fast the bullet was initially traveling. The plus sign indicates the direction, which makes sense, too. The units are also correct (m/s). We can test this using a limiting case: if the mass or speed of the bullet is zero, the block remains stationary after the collision.

Try it yourself A 0.020-kg bullet is fired horizontally into a 2.00-kg block of wood resting on a table. Immediately after the bullet joins the block, the block and bullet move in the positive x-direction at 4.0 m/s. What was the initial speed of the bullet?

Answer 400 m/s.

We could have worked Example 6.4 backward to determine the initial speed of the bullet before hitting the block (like the "Try it yourself" question). This exercise would be useful since the bullet travels so fast that it is difficult to measure its speed. Variations of this method are used, for example, to decide whether or not golf balls conform to the necessary rules. The balls are hit by the same mechanical launching impulse and the moving balls embed in another object. The balls' speeds are determined by measuring the speed of the object they embed in.

Determining the stopping time interval from the stopping distance

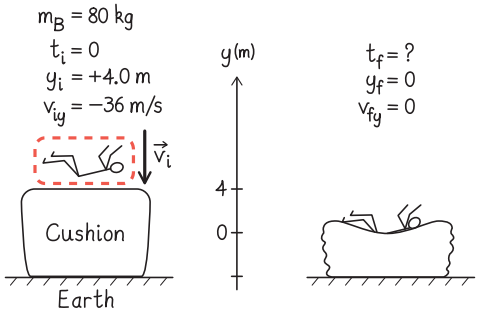
When a system collides with another object and stops—a car collides with a tree or a wall, a person jumps and lands on a solid surface, or a meteorite collides with Earth—the system travels what is called its **stopping distance**. By estimating the stopping distance of the system, we can estimate the stopping time interval.

Suppose that a car runs into a large tree and its front end crumples about 0.5 m. This 0.5 m, the distance that the center of the car traveled from the beginning of the impact to the end, is the car's stopping distance. Similarly, the depth of the hole left by a meteorite provides a rough estimate of its stopping distance when it collided with Earth. However, to use the impulse-momentum principle, we need the stopping time interval associated with the collision, not the stopping distance. Here's how we can use a known stopping distance to estimate the stopping time interval.

- Assume that the acceleration of the object while stopping is constant. In that case, the average velocity of the object while stopping is just the sum of the initial and final velocities divided by 2: $v_{\text{average } x} = (v_{\text{fx}} + v_{\text{ix}})/2$.
- Thus, the stopping displacement $(x_\text{f} - x_\text{i})$ and the stopping time interval $(t_\text{f} - t_\text{i})$ are related by the kinematics equation

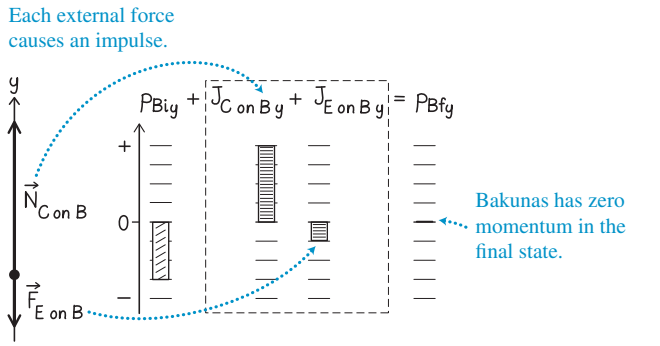
$$x_\text{f} - x_\text{i} = v_{\text{average } x}\,(t_\text{f} - t_\text{i}) = \frac{(v_{\text{fx}} + v_{\text{ix}})}{2}(t_\text{f} - t_\text{i})$$

- Rearrange this equation to determine the stopping time interval:



$$t_\text{f} - t_\text{i} = \frac{2(x_\text{f} - x_\text{i})}{v_{\text{fx}} + v_{\text{ix}}} \tag{6.10}$$

Equation (6.10) provides a method to convert stopping distance $x_\text{f} - x_\text{i}$ into stopping time interval $t_\text{f} - t_\text{i}$. Equation (6.10) can be applied to horizontal or vertical stopping.



EXAMPLE 6.5 Stopping the fall of a stunt diver

The record for the highest stunt fall without a parachute is 71 m (230 ft), held by 80-kg A. J. Bakunas. His fall was stopped by a large air cushion, into which he sank about 4.0 m. His speed was about 36 m/s (80 mi/h) when he reached the top of the air cushion. Estimate the average force that the cushion exerted on his body while stopping him.

Sketch and translate We focus only on the part of the fall when Bakunas is sinking into the cushion. The situation is sketched below. We choose Bakunas as the system and the y-axis pointing up. The initial state is just as he touches the cushion at position $y_\text{i} = +4.0$ m, and the final state is when the cushion has stopped him, at position $y_\text{f} = 0$. All motion is with respect to Earth. The other information about the process is given in the figure. Be sure to pay attention to the signs of the quantities (especially the initial velocity).

Simplify and diagram We draw a force diagram top right, modeling Bakunas as a point-like object. Since Bakunas's downward speed decreases, the cushion must be exerting an upward force on Bakunas of greater magnitude than the downward force that Earth exerts on him. Thus, the net force exerted on him points upward, in the positive y-direction. Using this information, we can draw a qualitative impulse-momentum bar chart for the process.

Represent mathematically Since all motion and all of the forces are in the vertical direction, we use the bar chart to help construct the vertical y-component form of the impulse-momentum equation [Eq. (6.7y)] to determine the force that the cushion exerts on Bakunas as he sinks into it:

$$m_\text{B} v_{\text{iy}} + (N_{\text{C on B }y} + F_{\text{E on B }y})(t_\text{f} - t_\text{i}) = m_\text{B} v_{\text{fy}}$$

Using the force diagram, we see that the y-components of the forces are $N_{\text{C on B }y} = +N_{\text{C on B}}$ and $F_{\text{E on B }y} = -F_{\text{E on B}} = -m_\text{B}\,g$, where $N_{\text{C on B}}$ is the magnitude of the average normal force that the cushion exerts on Bakunas, the force we are trying to estimate. Noting that $v_{\text{fy}} = 0$ and substituting the force components into the above equation, we get

$$m_\text{B} v_{\text{iy}} + [\,(+N_{\text{C on B}}) + (-m_\text{B} g)\,](t_\text{f} - t_\text{i}) = m_\text{B} \cdot 0$$
$$\Rightarrow m_\text{B} v_{\text{iy}} + (N_{\text{C on B}} - m_\text{B} g)(t_\text{f} - t_\text{i}) = 0$$

We can find the time interval that the cushion takes to stop Bakunas using Eq. (6.10) and noting that $v_{\text{fy}} = 0$:

$$t_\text{f} - t_\text{i} = \frac{2(y_\text{f} - y_\text{i})}{0 + v_{\text{iy}}}$$

(CONTINUED)

Solve and evaluate The stopping time interval while Bakunas sinks 4.0 m into the cushion is

$$t_f - t_i = \frac{2(0 - 4.0\text{ m})}{0 + (-36\text{ m/s})} = 0.22\text{ s}$$

Solving for $N_{C\text{ on }B}$, we get

$$\begin{aligned} N_{C\text{ on }B} &= \frac{-m_B v_{iy}}{(t_f - t_i)} + m_B g \\ &= \frac{-(80\text{ kg})(-36\text{ m/s})}{(0.22\text{ s})} + (80\text{ kg})(9.8\text{ N/kg}) \\ &= +13{,}000\text{ N} + 780\text{ N} = 14{,}000\text{ N} \end{aligned}$$

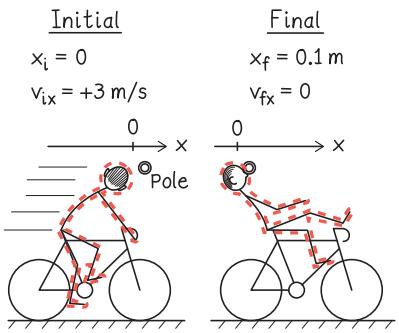
Wow, that is a huge force! To reduce the risk of injury, stunt divers practice landing so that the stopping force that a cushion exerts on them is distributed evenly over the entire body. The cushions must be deep enough so that they provide a long stopping time interval and thus a smaller stopping force. The same strategy is applied to developing air bags and collapsible frames for automobiles to make them safer for passengers during collisions.

Notice four important points. First, we've included only two significant digits since that is how many the data had. Second, it is very easy to make sign mistakes. A good way to avoid these is to draw a sketch that includes a coordinate system and labels showing the values of known physical quantities, including their signs. Third, the impulse due to Earth's gravitational force is small in magnitude compared to the impulse exerted by the air cushion. Lastly, the force exerted by the air cushion would be even greater if the stopping distance and consequently the stopping time interval were shorter.

Try it yourself Suppose that the cushion in this example stopped Bakunas in 1.0 m instead of 4.0 m. What would be the stopping time interval and the magnitude of the average force of the cushion on Bakunas?

Answer

The stopping time interval is 0.056 s, and the average stopping force is approximately 50,000 N.

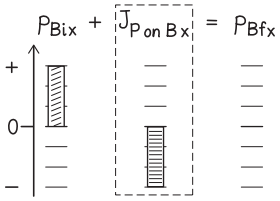


Order-of-magnitude estimate—will bone break?

The strategy that we used in the previous example can be used to analyze skull fracture injuries that might lead to concussions. Laboratory experiments indicate that the human skull can fracture if the compressive force exerted on it per unit area is $1.7 \times 10^8\text{ N/m}^2$. The surface area of the skull is much smaller than 1 m^2, so we will use square centimeters, a more reasonable unit of area for this discussion. Since $1\text{ m}^2 = 1 \times 10^4\text{ cm}^2$, we convert the compressive force per area to

$$(1.7 \times 10^8\text{ N/m}^2)\left(\frac{1\text{ m}^2}{1 \times 10^4\text{ cm}^2}\right) = 1.7 \times 10^4\text{ N/cm}^2$$

EXAMPLE 6.6 **Bone fracture estimation**[1]



A bicyclist is watching for traffic from the left while turning toward the right. A street sign hit by an earlier car accident is bent over the side of the road. The cyclist's head hits the pole holding the sign. Is there a significant chance that his skull will fracture?

Sketch and translate The process is sketched at the right. The initial state is at the instant that the head initially contacts the pole; the final state is when the head and body have stopped. The bicyclist is the system. We have been given little information, so we'll have to make some reasonable estimates of various quantities in order to make a decision about a possible skull fracture.

[1]This is a true story—it happened to one of the book's authors, Alan Van Heuvelen.

Simplify and diagram The bar chart illustrates the momentum change of the system and the impulse exerted by the pole that caused the change. The bicyclist was initially moving in the horizontal x-direction with respect to Earth, and not moving after the collision. The pole exerted an impulse in the negative x-direction on the cyclist. We'll need to estimate the following quantities: the mass and speed of the cyclist in this situation, the stopping time interval, and the area of contact. Let's assume that this is a 70-kg cyclist moving at about 3 m/s. His body keeps moving forward for a short distance after the bone makes contact with the pole. The skin indents some during the collision. Because of these two factors, we assume a stopping distance of about 10 cm. Finally, we assume an area of contact of about 4 cm^2. All of these numbers have large uncertainties and we are not worrying about significant digits, because this is just an estimate.

The pole's negative impulse on the bicyclist causes the momentum to decrease.

Represent mathematically We now apply the generalized impulse-momentum principle:

$$m_B v_{Bix} + (F_{P\text{ on }B\,x})(t_f - t_i) = m_B v_{Bfx} = 0$$

$$\Rightarrow F_{P\text{ on }B\,x} = -\frac{m_B v_{Bix}}{t_f - t_i}$$

We can use the strategy from the last example to estimate the stopping time interval $t_f - t_i$ from the stopping distance $x_f - x_i$:

$$t_f - t_i = \frac{2(x_f - x_i)}{v_{fx} + v_{ix}}$$

where v_{ix} is the initial velocity of the cyclist and $v_{fx} = 0$ is his final velocity.

Solve and evaluate Substituting the estimated initial velocity and the stopping distance into the preceding equation, we get an estimate for the stopping time interval:

$$t_f - t_i = \frac{2(x_f - x_i)}{v_{fx} + v_{ix}} = \frac{2(0.1\text{ m} - 0)}{0 + 3\text{ m/s}} = 0.067\text{ s}$$

Since this stopping time interval is an intermediate calculated value, we don't need to worry about its number of significant digits. When we complete our estimate, though, we will keep just one significant digit.

We can now insert our estimated values of quantities into the expression for the force exerted by the pole on the bicyclist:

$$F_{P\text{ on }B\,x} = -\frac{m_B v_{Bix}}{(t_f - t_i)}$$

$$= -\frac{(70\text{ kg})(3\text{ m/s})}{(0.067\text{ s})} = -3000\text{ N}$$

Our estimate of the force per area is

$$\frac{\text{Force}}{\text{Area}} = \frac{3000\text{ N}}{4\text{ cm}^2} \approx 800\text{ N/cm}^2$$

Is the bicyclist likely to fracture his skull? The force per area needed to break a bone is about 1.7×10^4 N/cm^2 = 17,000 N/cm^2. Our estimate could have been off by at least a factor of 10. The force per area is still too little for a fracture.

Try it yourself What would be the magnitude of the force exerted on the cyclist if he bounced back off the pole instead of stopping, assuming the collision time interval remains the same?

Answer ˙N 0009

REVIEW QUESTION 6.5 As the bullet enters the block in Example 6.4, the block exerts a force on the bullet, causing the bullet's speed to decrease to almost zero. Why did we not include the impulse exerted by the block on the bullet in our analysis of this situation?

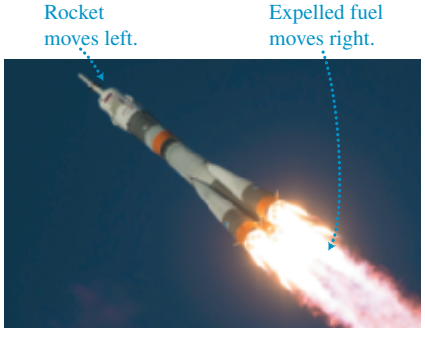
6.6 Jet propulsion

Cars change velocity because of an interaction between the tires and the road. Likewise, a ship's propellers push water backward; in turn, water pushes the ship forward. Once the ship or car is moving, the external force exerted by the water or the road has to balance the opposing friction force, or the vehicle's velocity will change.

What does a rocket push against in empty space to change its velocity? Rockets carry fuel that they ignite and then eject at high speed out of the exhaust nozzles (see **Figure 6.7**). Could this burning fuel ejected from the rocket provide the push to change its velocity? Choose the system to be the rocket and fuel together. If the rocket and fuel are at rest before the rocket fires its engines, then its momentum is zero. If there are no external impulses, then even after the rocket fires its engines, the momentum of the rocket-fuel system should still be zero. However, the burning fuel is ejected backward at high velocity from the exhaust nozzle and has a backward momentum. The rocket must now have a nonzero forward velocity. Let us analyze this idea quantitatively.

Imagine you are in a spacecraft traveling through space beside a rocket whose speed is the same as yours. All of a sudden you notice a burst of burning fuel that is ejected from the rocket. Let us predict what happens to the rocket's velocity. We choose

FIGURE 6.7 A rocket as it expels fuel.



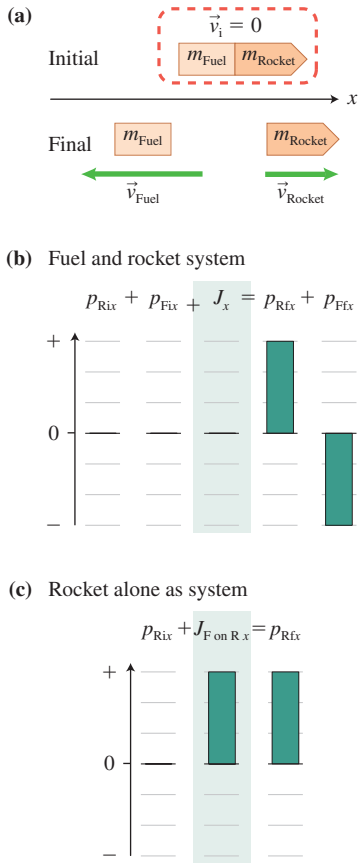


FIGURE 6.8 Analyzing a rocket ejecting fuel.

the rocket and its fuel as the system. Your spacecraft serves as the object of reference, and the $+x$-axis points in the direction of your motion. The rocket has zero velocity in the initial state with respect to you. Its final state is just after it expels fuel backward at high speed; the rocket in turn gains an equal magnitude of momentum in the forward direction (see **Figure 6.8a**). We can represent this process with an initial-final sketch and an impulse-momentum bar chart for the rocket-fuel system (Figure 6.8b) and use the bar chart to write momentum constancy mathematically:

$$m_{\text{Rocket}}v_{\text{Rocket }xi} + m_{\text{Fuel}}v_{\text{Fuel }xi} = m_{\text{Rocket}}v_{\text{Rocket }xf} + m_{\text{Fuel}}v_{\text{Fuel }xf}$$

The initial speeds of the rocket and fuel are zero with respect to you. Assuming that all the fuel is ejected at once at constant speed, we can find the velocity of the rocket:

$$0 = m_{\text{Rocket}}v_{\text{Rocket }x} + m_{\text{Fuel}}v_{\text{Fuel }x} \quad \Rightarrow \quad v_{\text{Rocket }x} = -\frac{m_{\text{Fuel}}v_{\text{Fuel }x}}{m_{\text{Rocket}}}$$

Here m_{Rocket} is the mass of the rocket without the fuel.

We can also choose the rocket alone as the system. The rocket pushes back on the fuel, expelling it backward at high speed ($v_{\text{Fuel }x} < 0$); the fuel in turn pushes forward against the rocket, exerting an impulse that causes the rocket's momentum and the velocity (assuming the mass of the rocket itself does not change) to increase ($v_{\text{Rocket }x} > 0$) (see Figure 6.8c).

The prediction matches the outcome of the experiment if all the fuel is ejected at once. If the fuel is ejected over some time interval, as happens in real rockets, the quantitative result is slightly different, but the essence will stay the same: you do not need anything to push against when trying to accelerate a rocket—expelling fuel is enough.

The main idea behind jet propulsion is that when an object ejects some of its mass in one direction, it accelerates in the opposite direction. This means that the same method that is used to speed up a rocket can also be used to slow it down. To do this, the fuel needs to be ejected in the same direction that the rocket is traveling.

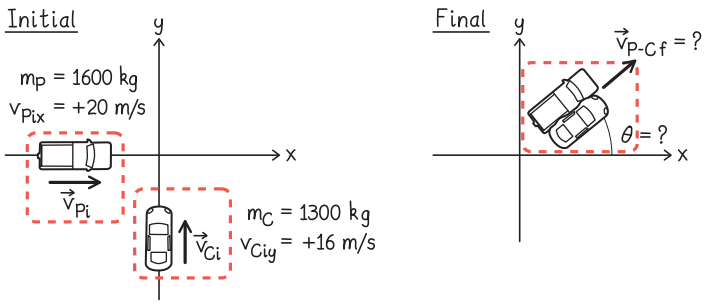
The force exerted by the fuel on a rocket during jet propulsion is called **thrust.** Typical large rocket thrusts measure in mega-newtons (10^6 N), and exhaust speeds are more than 10 times the speed of sound. Thrust provides the necessary impulse to change a rocket's momentum.

You can observe the principles of jet propulsion using a balloon. Attach an inflated balloon to a cart and then open the valve—the cart will accelerate in the direction opposite to the ejection of air from the balloon. This example is not exactly how the rocket accelerates, as there is air in the room, but in this case the interaction of the balloon and cart with the air from the balloon is much stronger than the interactions with the outside air (see the video). You can become your own jet propulsion machine by standing on Rollerblades or a skateboard and throwing a medicine ball or a heavy book forward or backward.

VIDEO 6.2

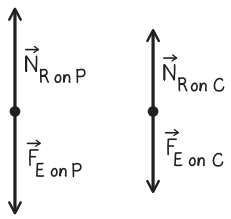
REVIEW QUESTION 6.6 The following equation is a solution for a problem. State a possible problem.

$$(2.0\text{ kg})(-8.0\text{ m/s}) + 0 = (2.0\text{ kg} + 58\text{ kg})\,v_x$$

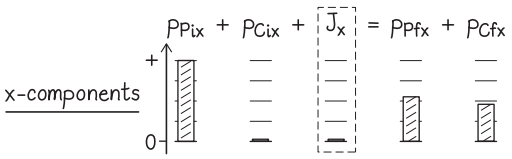


6.7 Collisions in two dimensions

So far, the collisions we have investigated have occurred along one axis. However, many collisions in real life do not occur along a straight line. For instance, colliding billiard balls and crashing cars (as you will see in Example 6.7) rarely move along the same line. Some of the most important applications of collisions in two dimensions are in the field of physics studying the behavior of light, elementary particles (see Example 6.8), and their interactions. In all collisions, the generalized impulse-momentum principle helps determine velocities of moving objects either before or after the collision. In car accidents, momentum conservation can help determine whether the drivers were speeding before the collision; in the field of elementary particles, the same principle can help discover a new particle.

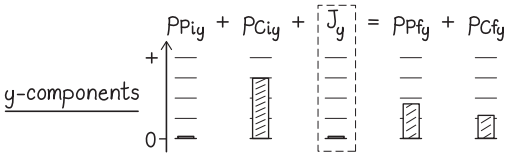


EXAMPLE 6.7 Truck collides with car



A 1600-kg pickup truck traveling east at 20 m/s collides with a 1300-kg car traveling north at 16 m/s. The vehicles remain tangled together after the collision. Determine the velocity (magnitude and direction) of the combined wreck immediately after the collision.

Sketch and translate We sketch the initial and final situations of the vehicles. We use a P subscript for the pickup and a C subscript for the car. The initial state is just before the collision; the final state is just after the vehicles collide and are moving together. We choose the two vehicles as the system. The object of reference is Earth; the positive x-axis points east and the positive y-axis points north.



Simplify and diagram Force diagrams represent the side view for each vehicle just before the collision. The net external force on the system is zero—it is an isolated system. We assume that the friction force exerted by the road is very small compared to the force that each vehicle exerts on the other. Thus, we ignore the impulse due to surface friction during the short collision time interval of about 0.1 s. We then apply momentum constancy in each direction. Impulse-momentum bar charts for the x-direction and for the y-direction are shown below.

The x-and y-components of momentum are independently constant.

Represent mathematically Now, convert each momentum bar in the x-component bar chart into a term in the x-component form of the impulse-momentum equation [Eq. (6.7x)] and each bar in the y-component bar chart into a term in the y-component form of the impulse-momentum equation [Eq. (6.7y)]. Notice that the x-component of the final velocity vector is $v_{P\text{-}C\,fx} = v_{P\text{-}C\,f}\cos\theta$ and the y-component is $v_{P\text{-}C\,fy} = v_{P\text{-}C\,f}\sin\theta$:

x-component equation:

$$m_P v_{Pix} + m_C v_{Cix} = (m_P + m_C) v_{P\text{-}C\,f}\cos\theta$$

y-component equation:

$$m_P v_{Piy} + m_C v_{Ciy} = (m_P + m_C) v_{P\text{-}C\,f}\sin\theta$$

We have two equations and two unknowns ($v_{P\text{-}C\,f}$ and θ). We can solve for both unknowns.

Solve and evaluate

x-component equation:

$$(1600\text{ kg})(20\text{ m/s}) + (1300\text{ kg})(0\text{ m/s}) = (2900\text{ kg})v_{P\text{-}C\,f}\cos\theta$$

y-component equation:

$$(1600\text{ kg})(0\text{ m/s}) + (1300\text{ kg})(16\text{ m/s}) = (2900\text{ kg})v_{P\text{-}C\,f}\sin\theta$$

Divide the left side of the second equation by the left side of the first equation and the right side of the second equation by the right of the first, and cancel the 2900 kg and $v_{P\text{-}C\,f}$ on the top and bottom of the right side. We get

$$\frac{(1300\text{ kg})(16\text{ m/s})}{(1600\text{ kg})(20\text{ m/s})} = \frac{\sin\theta}{\cos\theta} = \tan\theta = 0.65$$

A 33° angle has a 0.65 tangent. Thus, the vehicles move off at 33° above the $+x$-axis (the north of east direction). We can now use this angle with either the x-component equation or the y-component equation above to determine the speed of the two vehicles immediately after the collision. Using the x-component equation, we get

$$v_{P\text{-}C\,f} = \frac{(1600\text{ kg})(20\text{ m/s})}{(2900\text{ kg})\cos 33°} = 13\text{ m/s}$$

From the y-component equation, we have

$$v_{P\text{-}C\,f} = \frac{(1300\text{ kg})(16\text{ m/s})}{(2900\text{ kg})\sin 33°} = 13\text{ m/s}$$

The two equations give the same result for the final speed, a good consistency check. For collisions in which vehicles lock together like this, police investigators commonly use the lengths of the skid marks along with the direction of the vehicles after the collision to determine their initial speeds. This allows them to determine whether either vehicle was exceeding the speed limit before the collision.

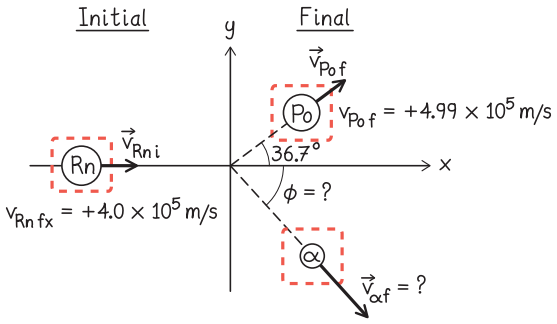
Try it yourself Use a limiting case analysis and the x- and y-component forms of the impulse-momentum equation to predict what would happen during the collision if the pickup had infinite mass. Is the answer reasonable?

Answer If we place ∞ instead of the 1600-kg mass of the pickup in the following:

$$\tan\theta = \frac{\sin\theta}{\cos\theta} = \frac{(1300\text{ kg})(16\text{ m/s})}{(1600\text{ kg})(20\text{ m/s})}$$

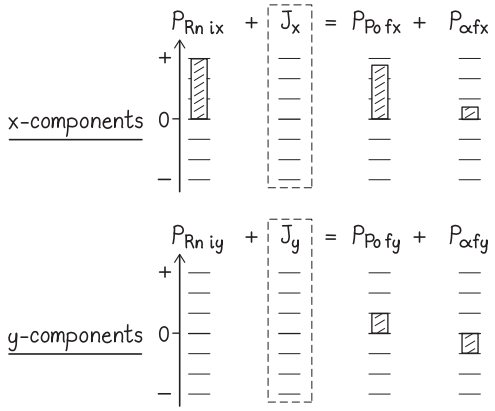
the left side of the equation becomes zero. Then $\tan\theta = 0$. The pickup would move straight ahead when hitting the car. In other words, the collision with the car would not change the direction of travel of the pickup. The result seems reasonable if the mass of the pickup was large compared to the mass of the car.

An object breaks into parts (radioactive decay)



We will learn in the chapter on nuclear physics (Chapter 29) that the nuclei of some atoms are unstable and spontaneously break apart. In a process called *alpha decay*, the nucleus of the atom breaks into a daughter nucleus, which is slightly smaller and lighter than the original parent nucleus, and an even smaller alpha particle (given the symbol α, though it is actually a helium nucleus). For example, radon (the radioactive gas that is sometimes found in basements) decays into a polonium nucleus (the daughter) and an alpha particle.

Radon is produced by a series of decay reactions starting with heavier elements in the soil, such as uranium. Radon diffuses out of the soil and can enter a home through cracks in its foundation. If you are in your basement when a radon atom near you undergoes alpha decay, the fast-moving alpha particle it releases could cause a gene mutation in your body. In the next example, we will analyze alpha decay of radon using the idea of momentum conservation.



EXAMPLE 6.8 **Radioactive decay of radon**

The nucleus of a radioactive radon atom in the air near you decays to a polonium nucleus and an alpha particle. With what speed does the alpha particle move if the radon nucleus was moving at 4.00×10^5 m/s and the polonium nucleus produced by the decay moves at 4.99×10^5 m/s at an angle of 36.7° above the initial path of the radon nucleus? What is the angle between the velocity of the alpha particle and the velocity of the radon nucleus? Use the relative masses of the nuclei involved: radon has mass $222m$, polonium $218m$, and the alpha particle $4m$.

Sketch and translate An initial-final sketch of the situation is shown below. We choose the positive x-axis to point in the initial direction of the radon nucleus, and the system consists of the three nuclei. We do not know the exact value of the angle ϕ, but we hypothesize that the direction of the alpha particle is below the radon's path if the momentum is constant in this direction. We might need to revise our sketch after we determine the angle. The magnitude and direction of the velocity $\vec{v}_{\alpha f}$ of the alpha particle are the unknowns to be determined.

Simplify and diagram Assume that there are no external forces exerted on the system, meaning that the system is isolated and thus its momentum is constant. The impulse-momentum bar charts at top right represent the process separately for the x- and y-directions.

We don't know in advance which of the bars in the x-component bar chart is larger in the final state, but we know that their heights added together should be equal to the height of the initial momentum bar. For the y-component bar chart, we know that the bars in the final state should have the same height, but should be drawn in opposite directions. This means that the alpha particle does indeed move along the line below the x-axis.

Represent mathematically Use the bar charts to help apply the impulse-momentum principle for the process. The momentum constancy equation for the x-axis is

$$m_{Rn} v_{Rn\,ix} + 0 = m_{Po} v_{Po\,f} \cos 36.7° + m_\alpha v_{\alpha f} \cos \phi$$

The momentum constancy equation for the y-axis is

$$0 = m_{Po} v_{Po\,f} \sin 36.7° - m_\alpha v_{\alpha f} \sin \phi$$

Solve and evaluate Plugging values for the known quantities into the above, we have

$$222m(4.00 \times 10^5 \text{ m/s}) + 0 = 218m(4.99 \times 10^5 \text{ m/s})\cos 36.7° + 4m v_{\alpha f} \cos \phi$$

$$0 = 218m(4.99 \times 10^5 \text{ m/s})\sin 36.7° - 4m v_{\alpha f} \sin \phi$$

We now have two independent equations and two unknowns, $v_{\alpha f}$ and ϕ. Note that the mass m cancels from each equation. One way to solve for the two unknowns is to first insert the known information into each equation and get an expression involving $v_{\alpha f}$ and ϕ. From the x-equation we get

$$v_{\alpha f}\cos\phi = \frac{222m}{4m}(4.00\times10^5\ \text{m/s}) - \frac{218m}{4m}(4.99\times10^5\ \text{m/s})\cos 36.7^\circ$$
$$= 3.95\times10^5\ \text{m/s}$$

From the y-equation we get

$$v_{\alpha f}\sin\phi = \frac{218m}{4m}(4.99\times10^5\ \text{m/s})\sin 36.7^\circ = 162.5\times10^5\ \text{m/s}$$

Recall that $\sin^2\phi + \cos^2\phi = 1$. If we square each of the previous equations and add them together, we can factor out the $v_{\alpha f}^2$ from each term and cancel the $\sin^2\phi + \cos^2\phi$, which equals 1. We solve what is left for $v_{\alpha f}$:

$$v_{\alpha f}^2\cos^2\phi + v_{\alpha f}^2\sin^2\phi = (3.95\times10^5\ \text{m/s})^2 + (162.5\times10^5\ \text{m/s})^2$$
$$= 2.64\times10^{14}\ \text{m}^2/\text{s}^2$$
$$v_{\alpha f}^2(\cos^2\phi + \sin^2\phi) = 2.64\times10^{14}\ \text{m}^2/\text{s}^2$$
$$\Rightarrow v_{\alpha f} = \sqrt{2.64\times10^{14}\ \text{m}^2/\text{s}^2}$$

Taking this square root, we find the speed of the alpha particle after the decay:

$$v_{\alpha f} = 162.5\times10^5\ \text{m/s}$$

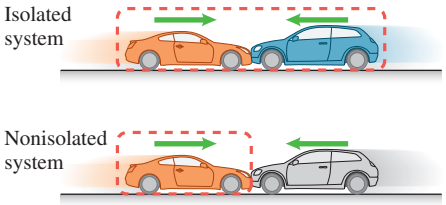
We can then use the velocity components to find ϕ:

$$\frac{v_{\alpha f}\sin\phi}{v_{\alpha f}\cos\phi} = \tan\phi = \frac{162.5\times10^5\ \text{m/s}}{3.95\times10^5\ \text{m/s}} = 41.14$$

or $\phi = 88.6^\circ$, that is, 88.6° below the x-axis. The alpha particle travels almost perpendicularly to the direction of the original radon nucleus—and pretty fast.

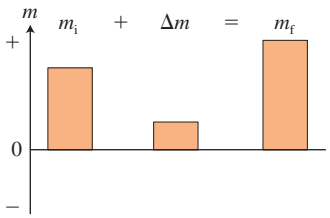
The speeding alpha particle can pass through tissue and collide with atoms and molecules in the body, dislodging electrons and creating damaging ions. Radon exposure causes approximately 15,000 cases of lung cancer each year.

Try it yourself Francium nuclei undergo radioactive decay by emitting either an alpha particle or a *beta particle* (an electron). When a particle is emitted from a nucleus, the nucleus starts moving, too (we say that it recoils, similar to a gun recoiling after shooting a bullet). An alpha particle is about 8000 times more massive than a beta particle. If the particles are emitted with the same speed, in which case is the recoil speed of the nucleus that is left after an alpha or a beta particle is emitted greater?



Answer

Since the mass of the alpha particle is much greater than the mass of the beta particle, and they are traveling with the same speed, the momentum of the alpha particle is much greater than the momentum of the beta particle. Therefore, the nucleus that is left will have a greater recoil speed during alpha decay.



REVIEW QUESTION 6.7 Object A, moving in the positive x-direction, collides with object B, moving in the negative y-direction. After colliding, the objects stick together. Is it possible for both objects to stop after the collision? Explain your answer.

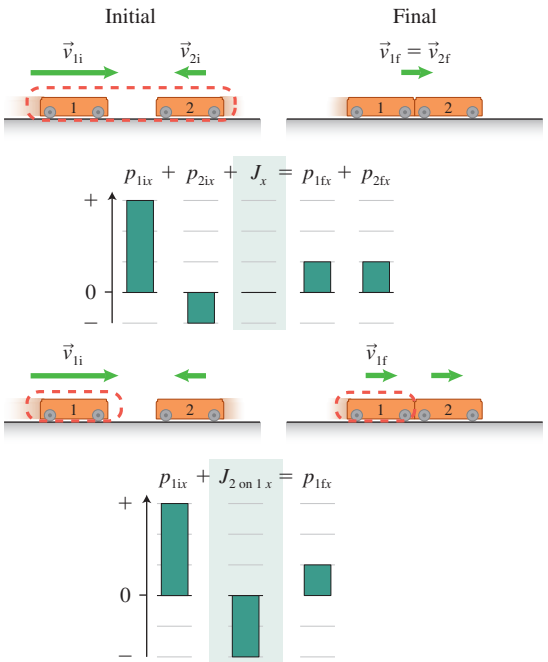
Summary

Isolated system An isolated system is one in which the objects interact only with each other and not with the environment, or the sum of external forces exerted on it is zero. (Sections 6.1–6.2)

Mass is a conserved quantity. It is constant in an isolated system. If the system is not isolated and its mass changes, we can always find the system in which the mass is constant. (Section 6.1)

$$m_i + \Delta m = m_f$$

Linear momentum $\vec{p}$ is a vector quantity that is the product of an object's mass m and velocity $\vec{v}$. The total momentum of the system is the sum of the momenta of all objects in the system. (Section 6.2)



$$\vec{p} = m\vec{v} \qquad \text{Eq. (6.1)}$$

$$\vec{p}_{\text{system}} = \vec{p}_1 + \vec{p}_2 + \cdots$$

Impulse $\vec{J}$ is the product of the average external force $\vec{F}_{\text{av}}$ exerted on an object during a time interval Δt and that time interval. (Section 6.3)

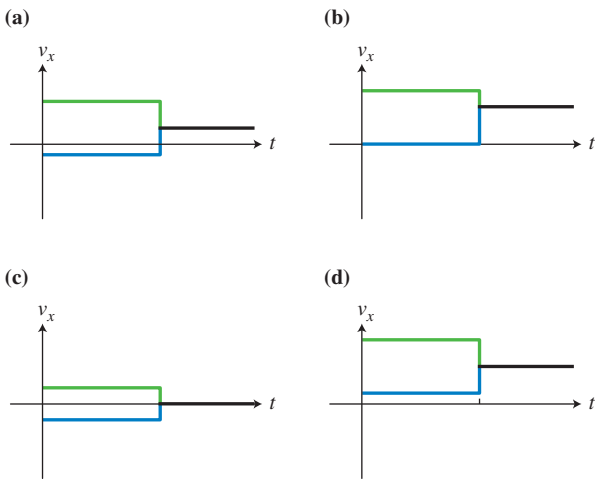
$$\vec{J} = \vec{F}_{\text{av}}(t_f - t_i) \qquad \text{Eq. (6.5)}$$

Generalized impulse-momentum principle The change in momentum of a system is equal to the net external impulse exerted on it. If the net impulse is zero, then the momentum of the system is constant. If the objects outside the system exert forces on it and change its momentum, we can always redefine the system by including all interacting objects to keep the momentum of this new system constant. Therefore, momentum is a conserved quantity. (Section 6.4)

$$(m_1\vec{v}_{1i} + m_2\vec{v}_{2i} + \cdots) + \Sigma\vec{F}_{\text{on Sys}}\,\Delta t = (m_1\vec{v}_{1f} + m_2\vec{v}_{2f} + \cdots) \qquad \text{Eq. (6.8)}$$

x- and y-component forms:

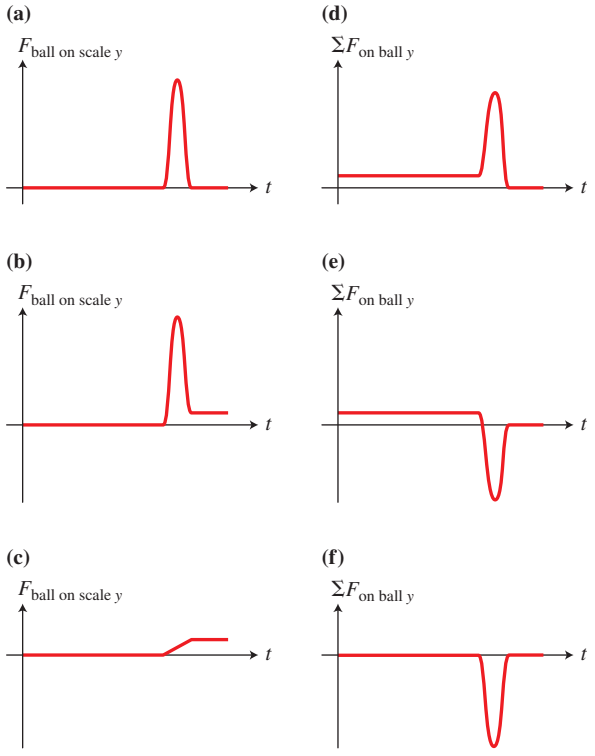
$$m_1v_{1ix} + m_2v_{2ix} + \Sigma F_{\text{on Sys}\,x}\,\Delta t = m_1v_{1fx} + m_2v_{2fx} \qquad \text{Eq. (6.9}x\text{)}$$



$$m_1v_{1iy} + m_2v_{2iy} + \Sigma F_{\text{on Sys}\,y}\,\Delta t = m_1v_{1fy} + m_2v_{2fy} \qquad \text{Eq. (6.9}y\text{)}$$

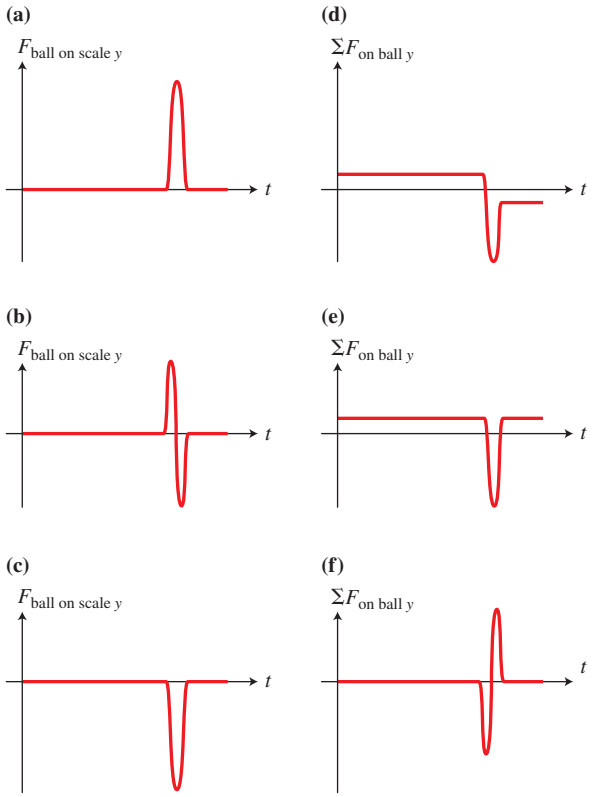
Questions

Multiple Choice Questions



1. The gravitational force that Earth exerts on an object causes an impulse of $+10\ \text{N}\cdot\text{s}$ in one experiment and $+1\ \text{N}\cdot\text{s}$ on the same object in another experiment. How can this be?
   (a) The mass of the object changed.
   (b) The time intervals during which the force was exerted are different.
   (c) The magnitudes of the force were different.
2. A bullet fired at a door makes a hole in the door but does not open it. Your finger does not make a hole in the door but does open it. Why?
   (a) The bullet is too small.
   (b) The force exerted by the bullet is not enough to open the door.
   (c) A finger exerts a smaller force but the time interval is much longer.
   (d) The bullet goes through the door and does not exert a force at all.
3. How would you convince somebody that the momentum of an isolated system is constant?
   (a) It is a law; thus, you do not need to convince anybody.
   (b) Use an example from a textbook to show that the sum of the initial and final velocities of the objects involved in a collision are the same.
   (c) Derive it from Newton's second and third laws.
   (d) Use it to make predictions about a new experiment, and then compare the outcome to the prediction.
   (e) Both (c) and (d) will work.
4. A wagon full of medicine balls is rolling along a street. Suddenly one medicine ball (3 kg) falls off the wagon. What happens to the speed of the wagon?
   (a) The wagon slows down.
   (b) The speed of the wagon does not change.
   (c) The wagon speeds up.
   (d) Additional information about the ball's motion is needed to answer.
5. When can you apply the idea that momentum is constant to solve a problem?
   (a) When the system is isolated
   (b) When the system is not isolated but the time interval when the external forces are exerted is very small
   (c) When the external forces are much smaller than the internal forces
6. Choose an example in which the momentum of a system is not constant.
   (a) A frog on a floating piece of wood jumping off the wood, with the frog and the wood as the system
   (b) A freely falling metal ball, with the ball as the system
   (c) A freely falling metal ball, with the ball and Earth as the system
   (d) It is not possible to give an example since the momentum of a system is always constant.
7. **Figure Q6.7** shows the velocity-versus-time graphs of two carts on a horizontal track before and after a collision during which the carts stick together. The green and blue lines show the velocities of the carts before they collide, and the black lines show the velocity of the carts joined together after the collision. Which graph *cannot* represent the collision of the carts with equal masses?

FIGURE Q6.7

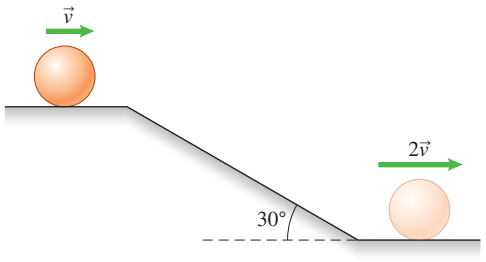


8. Which is a safer car bumper in a collision: one that is flexible and retracts or one that is rigid? Why?
   (a) The retractable bumper, because softer things withstand collisions better
   (b) The retractable bumper, because it extends the time interval of the collision, thus reducing the force exerted on the car
   (c) The rigid bumper, because it does not change shape so easily
9. Why does an inflated balloon shoot across a room when air is released from it?
   (a) Because the outside air pushes on the balloon
   (b) Because the momentum of the balloon-air system is constant
   (c) Because the air inside the balloon pushes on the balloon, exerting the same force that the balloon exerts on the air
   (d) Both b and c are correct.
10. In which situation does the momentum of a tennis ball change more?
    (a) It hits the racket and stops.
    (b) It hits the racket and flies off in the opposite direction.
    (c) It misses the racket and continues moving.
11. A toy car with very low friction wheels and axles rests on a level track. In which situation will its speed increase more?
    (a) It is hit from the rear by a wad of clay that sticks to the car.
    (b) It is hit by a rubber ball with the same mass and velocity of the clay that rebounds in the opposite direction after hitting the car.
12. You hold a clay ball above a scale and then drop it. After hitting the scale, the ball sticks to it. In **Figure Q6.12**, which of the graphs (a) to (c) correctly shows the qualitative time dependence of the force exerted by the ball on the scale, and which of the graphs (d) to (f) correctly shows the qualitative time dependence of sum of the forces exerted on the ball? Assume the y-axis points vertically down.

FIGURE Q6.12

13. You hold a rubber ball above a scale and then drop it. After hitting the scale, the ball bounces up. In **Figure Q6.13**, which of the graphs (a) to (c) correctly shows the qualitative time dependence of the force exerted by the ball on the scale, and which of the graphs (d) to (f) correctly shows the qualitative time dependence of sum of the forces exerted on the ball? Assume the y-axis points vertically down.

FIGURE Q6.13



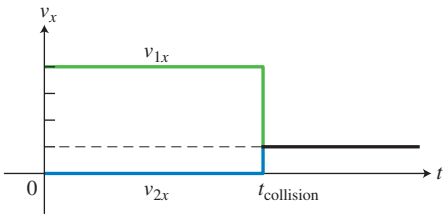
14. Two battery-powered fan carts are resting on a frictionless horizontal track. The mass of cart A is twice the mass of cart B. The carts are released so they start moving to the right. Which answer and explanation correctly compare the linear momentum of the carts after traveling the same distance? Assume that the force exerted by the air on the carts is the same for both carts and remains constant while the carts are moving.
    (a) $p_A = p_B$ because the sums of the forces exerted on the carts are equal.
    (b) $p_A = p_B$ because the distances traveled are equal.
    (c) $p_A > p_B$ because the air exerts a force on cart A for a longer time interval than on cart B.
    (d) $p_A > p_B$ because the heavier cart A pushes back on the air with a larger force than does cart B.
    (e) $p_A < p_B$ because the final velocity of cart B is larger than the final velocity of cart A.
    (f) $p_A < p_B$ because cart B has a larger acceleration than does cart A.

Conceptual Questions

15. According to a report on traumatic brain injury, woodpeckers smack their heads against trees at a force equivalent to 1200 g's without suffering brain damage. This statement contains one or more mistakes. Identify the mistakes in this statement.
16. Jim says that momentum is not a conserved quantity because objects can gain and lose momentum. Do you agree or disagree? If you disagree, what can you do to convince Jim of your opinion?
17. Say five important things about momentum (for example, momentum is a vector quantity). How does each statement apply to real life?
18. Three people are observing the same car. One person claims that the car's momentum is positive, another person claims that it is negative, and the third person says that it is zero. Can they all be right at the same time? Explain.
19. When would a ball hitting a wall have a greater change in momentum: when it hits the wall and bounces back at the same speed or when it hits and sticks to the wall? Explain your answer.
20. In the previous question, in which case does the wall exert a greater force on the ball? Explain.
21. Explain the difference between the concepts of constancy and conservation. Provide an example of a conserved quantity and a nonconserved quantity.
22. Why do you believe that momentum is a conserved quantity?
23. A heavy bar falls straight down onto the bed of a rolling truck. What happens to the momentum of the truck at the instant the bar lands on it? Explain by drawing sketches of possible situations and their corresponding impulse-momentum bar charts. How many correct answers do you think are possible? Make sure you think of what "falls straight down" means.
24. Construct impulse-momentum bar charts to represent a falling ball in (a) a system whose momentum is not constant and (b) a system whose momentum is constant. In the initial state, the ball is at rest; in the final state, the ball is moving.
25. A person moving on Rollerblades throws a medicine ball in the direction opposite to her motion. Construct an impulse-momentum bar chart for this process. The person is the system.
26. A small ball of mass m rolls at a constant speed v along a horizontal surface, then rolls down an incline and continues rolling along a lower horizontal surface with a constant speed $2v$ (see **Figure Q6.26**). Analyze the motion of the ball (the system) using a momentum approach. Identify segments of the ball's motion where the ball's momentum is changing (either in magnitude or in direction). Determine the direction of the impulse exerted on the ball during these segments and draw corresponding impulse vectors. Assume that the ball is in contact with the surface at all times and that it does not slip.

FIGURE Q6.26

Problems



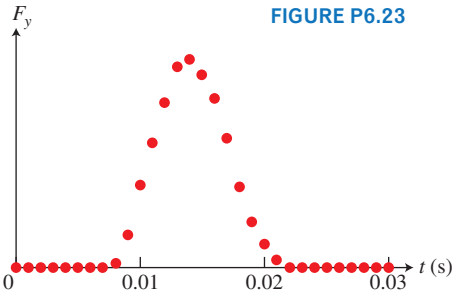
Below, BIO indicates a problem with a biological or medical focus. Problems labeled EST ask you to estimate the answer to a quantitative problem rather than derive a specific answer. Asterisks indicate the level of difficulty of the problem. Problems with no * are considered to be the least difficult. A single * marks moderately difficult problems. Two ** indicate more difficult problems.

6.2 Linear momentum

1. You and a friend are playing tennis. (a) What is the magnitude of the momentum of the 0.057-kg tennis ball when it travels at a speed of 30 m/s? (b) At what speed must your 0.32-kg tennis racket move to have the same magnitude momentum as the ball? (c) If you run toward the ball at a speed of 5.0 m/s, and the ball is flying directly at you at a speed of 30 m/s, what is the magnitude of the total momentum of the system (you and the ball)? Assume your mass is 60 kg. In every case specify the object of reference.
2. You are hitting a tennis ball against a wall. The 0.057-kg tennis ball traveling at 25 m/s strikes the wall and rebounds at the same speed. (a) Determine the ball's original momentum (magnitude and direction). (b) Determine the ball's change in momentum (magnitude and direction). What is your object of reference?

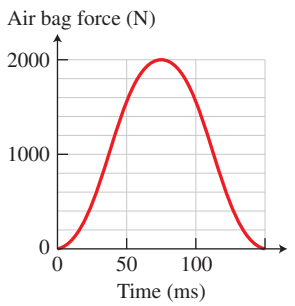
3. A ball of mass m and speed v travels horizontally, hits a wall, and rebounds. Another ball of the same mass and traveling at the same speed hits the wall and sticks to it. Which ball has a greater change in momentum as a result of the collision? Explain your answer.
4. **Figure P6.4** shows the velocity-versus-time graph before and after the collision of two carts on a horizontal track. After the collision the carts stick together. Green and blue lines show the velocities of cart 1 and cart 2, respectively, before the collision. The black line shows the velocity of the carts joined together after the collision. Determine the ratio of the carts' masses m_1/m_2.

FIGURE P6.4



5. A 1300-kg car is traveling at a speed of 10 m/s with respect to the ground when the driver accelerates to make a green light. The momentum of the car increases by 12,800 kg · m/s. List all the quantities you can determine using this information and determine three of those quantities.
6. * The rules of tennis specify that the 0.057-kg ball must bounce to a height of between 53 and 58 inches when dropped from a height of 100 inches onto a concrete slab. What is the change in the momentum of the ball during the collision with the concrete? You will have to use some free-fall kinematics to help answer this question. Ignore air resistance.
7. * A cart of mass m moving right at speed v with respect to the track collides with a cart of mass $0.7m$ moving left. What is the initial speed of the second cart if after the collision the carts stick together and stop?
8. * A cart of mass m moving right collides with an identical cart moving right at half the speed. The carts stick together. What is their speed after the collision?
9. **EST** Estimate your momentum when you are walking at your normal pace.

6.3 Impulse and momentum

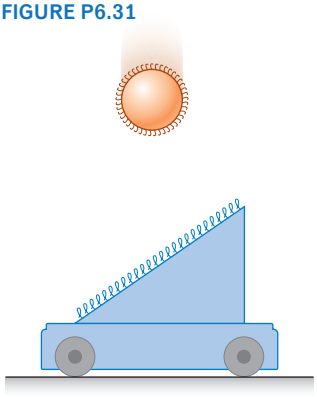


10. A 100-g apple is falling from a tree. What is the impulse that Earth exerts on it during the first 0.50 s of its fall? The next 0.50 s?
11. * The same 100-g apple is falling from the tree. What is the impulse that Earth exerts on it during the first 0.50 m of its fall? The next 0.50 m?
12. Why does Earth exert the same impulse during the two time intervals in Problem 6.10 but different impulses during the same distances traveled in Problem 6.11?
13. * **Van hits concrete support** In a crash test, a 2000-kg van collides with a concrete support. The stopping time interval for the collision is 0.10 s, and the impulse exerted by the support on the van is 7.5×10^3 N · s. (a) Determine everything you can about the collision using this information. (b) If the van is constructed to collapse more during the collision so that the time interval during which the impulse is exerted is tripled, what is the average force exerted by the concrete support on the van?
14. **BIO** **Force exerted by heart on blood** About 80 g of blood is pumped from a person's heart into the aorta during each heartbeat. The blood starts at rest with respect to the body and has a speed of about 1.0 m/s in the aorta. If the pumping takes 0.17 s, what is the magnitude of the average force exerted by the heart on the blood?
15. * The train tracks on which a train travels exert a 2.0×10^5-N friction force on the train, causing it to stop in 50 s. (a) Determine the average force needed to stop the train in 25 s. (b) Determine the stopping time interval if the tracks exert a 1.0×10^5-N friction force on the train.
16. ** **EST** Your friend is catching a falling basketball after it has passed through the basket. Her hands move straight down 0.20 m while catching the ball. Estimate (a) the time interval for the ball to stop as she catches it and (b) the average force that her hands exert on the ball while catching it. Indicate any assumptions or estimates you have to make in order to answer the questions.
17. **BIO** **Traumatic brain injury** According to a report on traumatic brain injury, the force that a professional boxer's fist exerts on his opponent's head is equivalent to being hit with a 5.9-kg bowling ball traveling at 8.9 m/s that stops in 0.018 s. Determine the average force that the fist exerts on the head.
18. * A 65-kg astronaut pushes against the inside back wall of a 2000-kg spaceship and moves toward the front. Her speed increases from 0 to 1.6 m/s. (a) If her push lasts 0.30 s, what is the average force that the astronaut exerts on the wall of the spaceship? (b) If the spaceship was initially at rest, with what speed does it recoil? (c) What was the object of reference that you used to answer parts (a) and (b)?
19. * You decide to use your garden hose to wash your garage door. Every second, 0.8 kg of water leaves the hose at a speed of 9.0 m/s with respect to the hose, hits the garage door perpendicularly, and spills down the door surface. Determine the magnitude of the force that the water jet from the hose exerts on the door. What assumptions did you make?
20. * An egg rolls off a kitchen counter and breaks as it hits the floor. How large is the impulse that the floor exerts on the egg, and how large is the force exerted on the egg by the floor when stopping it? The counter is 1.0 m high, the mass of the egg is about 50 g, and the time interval during the collision is about 0.010 s.
21. ** **Proportional reasoning** During a collision when an average stopping force F is exerted on a car by an obstacle, the car's bumper retracts a distance Δx. These two quantities are related by the equation $F\Delta x = 0.5mv_0^2$. Use proportional reasoning to determine (a) the necessary percent change in the retraction distance so that the average force required to stop a car is reduced by 20% and (b) the percent change in initial to final speed that would produce the same reduction in force.
22. (a) What force is required to stop a 1500-kg car in a distance of 0.20 m if it is initially moving at 2.2 m/s? (b) What if the car is moving at 4.5 m/s?
23. ** **EST** You drop a 78-g ball vertically onto a force sensor that is 0.4 m below the ball's initial position. The ball bounces off the force sensor after the collision. **Figure P6.23** shows the time dependence of the force exerted by the ball on the force sensor. Estimate the expected peak magnitude of the force. Indicate any assumptions that you made, and discuss how they affect the estimated peak value. (Hint: The area under the force-versus-time curve has approximately the shape of a triangle.)

FIGURE P6.23

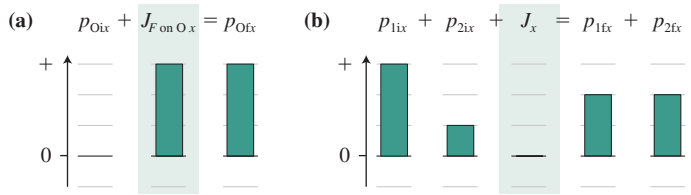
24. * **Air bag force on head** The graph in **Figure P6.24** shows the time variation of the force that an automobile's air bag exerts on a person's head during a collision. The mass of the head is 8.0 kg. Determine (a) the total impulse of the force exerted by the air bag on the person's head and (b) the person's speed just before the collision occurred.

FIGURE P6.24



25. * **Equation Jeopardy 1** Invent a problem for which the solution is $(27\text{ kg})(-3.0\text{ m/s}) + (30\text{ kg})(+4.0\text{ m/s}) = (27\text{ kg} + 30\text{ kg})v$.
26. * **Equation Jeopardy 2** Invent a problem for which the solution is $(0.020\text{ kg})(300\text{ m/s}) - (10\text{ N})(0.40\text{ s}) = (0.020\text{ kg})(100\text{ m/s})$.

6.4 The generalized impulse-momentum principle



27. * Two carts (100 g and 150 g) on an air track are separated by a compressed spring. The spring is released. Represent the process with a momentum bar chart (a) with one cart as the system and (b) with both carts as the system. (c) Write expressions for all of the physical quantities you can from this information. Identify your object of reference.
28. * A tennis ball of mass m hits a wall at speed v and rebounds at about the same speed. Represent the process with an impulse-momentum bar chart for the ball as the system. Using the bar chart, develop an expression for the change in the ball's momentum. What is the object of reference?
29. * A tennis ball traveling at a speed of v stops after hitting a net. Represent the process with an impulse-momentum bar chart for the ball as the system. Develop an expression for the ball's change in momentum. What is the object of reference?
30. * You drop a happy ball and a sad ball of the same mass from height h (see Example 6.3). One ball hits the ground and rebounds almost to the original height. The other ball does not bounce. Represent each process with a bar chart, starting just before the balls hit the ground to just after the first ball rebounds and the other ball stops. Choose the ball as the system.
31. * You have two objects: a ball that is covered with the hook side of Velcro and an incline covered with the loop side of Velcro that is fixed onto a low-friction cart. The ball is dropped vertically onto the incline, which is at rest (see **Figure P6.31**). When the ball collides with the incline, it sticks to it without moving relative to it. What happens to the cart after the ball sticks to the incline? Will the cart move or remain stationary? Explain. Represent the process with impulse-momentum bar charts.

FIGURE P6.31

32. * You hold a beach ball above your head and then throw it upward. Represent the motion of the ball with an impulse-momentum bar chart for (a) the ball as the system and (b) the ball and Earth as the system.
33. * A basketball player drops a 0.60-kg basketball vertically so that it is traveling at 6.0 m/s when it reaches the floor. The ball rebounds upward at a speed of 4.2 m/s. (a) Determine the magnitude and direction of the ball's change in momentum. (b) Determine the average net force that the floor exerts on the ball if the collision lasts 0.12 s.
34. * **Bar chart Jeopardy** Invent a problem for each of the bar charts shown in **Figure P6.34**.

FIGURE P6.34

6.5 Skills for analyzing problems using impulse and momentum

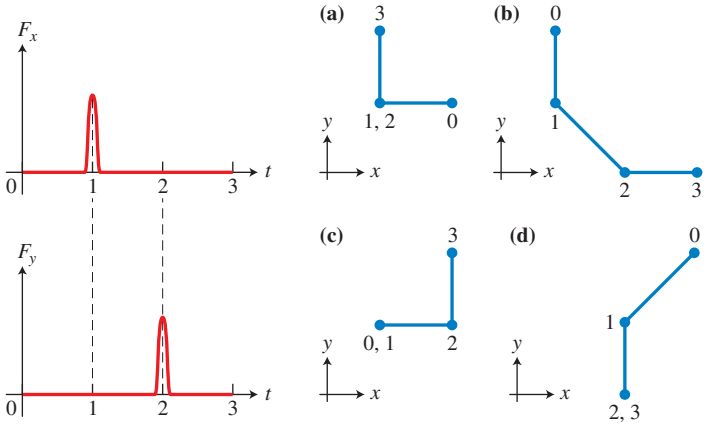
35. * A baseball bat contacts a 0.145-kg baseball for 1.3×10^{-3} s. The average force exerted by the bat on the ball is 8900 N. If the ball has an initial velocity of 36 m/s toward the bat and the force of the bat causes the ball's motion to reverse direction, what is the ball's speed as it leaves the bat?
36. A cannon mounted on the back of a ship fires a 50-kg cannonball in the horizontal direction at a speed of 150 m/s. If the cannon and ship have a combined mass of 40,000 kg and are initially at rest, what is the speed of the ship just after shooting the cannon? What assumptions did you make?
37. A 10-kg sled carrying a 30-kg child glides on a horizontal, frictionless surface at a speed of 6.0 m/s toward the east. The child jumps off the back of the sled, propelling it forward at 20 m/s. What was the child's velocity in the horizontal direction relative to the ground at the instant she left the sled?
38. A 10,000-kg coal car on the Great Northern Railroad coasts under a coal storage bin at a speed of 2.0 m/s. As it goes under the bin, 1000 kg of coal is dropped into the car. What is the final speed of the loaded car?
39. * **Avoiding chest injury** A person in a car during a sudden stop can experience potentially serious chest injuries if the combined force exerted by the seat belt and shoulder strap exceeds 16,000 N. Describe what it would take to avoid injury by estimating (a) the minimum stopping time interval and (b) the corresponding stopping distance, assuming an initial speed of 16 m/s. Indicate any other assumptions you made.
40. * **Bruising apples** An apple bruises if a force greater than 8.0 N is exerted on it. Would a 0.10-kg apple be likely to bruise if it falls 2.0 m and stops after sinking 0.060 m into the grass? Explain.
41. * **Fast tennis serve** The fastest server in women's tennis is Sabine Lisicki, who recorded a serve at 131 mph (211 km/h) in 2014. Suppose that the mass of her racket was 328 g and the mass of the ball was 57 g. If her racket was moving at 210 km/h when it hit the ball, approximately what was the racket's speed after hitting the ball? Indicate any assumptions you made.
42. * You are in an elevator whose cable has just broken. The elevator is falling at 20 m/s when it starts to hit a shock-absorbing device at the bottom of the elevator shaft. If you are to avoid injury, the upward force that the floor of the elevator exerts on your upright body while stopping should be no more than 8000 N. Determine the minimum stopping distance needed to avoid injury (do not forget to include your mass in the calculations). What assumptions did you make? Do these assumptions make the stopping distance smaller or larger than the real-world value?
43. ** You jump from the window of a burning hotel and land in a safety net that stops your fall in 1.0 m. Estimate the average force that the net exerts on you if you enter the net at a speed of 24 m/s. What assumptions did you make? If you did not make these assumptions, would the stopping distance be smaller or larger?
44. * After a 70-kg person steps from a boat onto the shore, the boat moves away with a speed of 0.7 m/s with respect to the shore. If the same person steps from the shore onto the boat, the person and the boat move away from the shore with the speed of 0.5 m/s. Assume that the initial speed of the person with respect to the shore is the same in both cases and that the person is moving in a horizontal direction. (a) Draw impulse-momentum bar charts for both situations and (b) determine the mass of the boat and the speed of the person.
45. * BIO **Leg injuries during car collisions** During a car collision, the knee, thighbone, and hip can sustain a force no greater than 4000 N. Forces that exceed this amount could cause dislocations or fractures. Assume that in a collision a knee stops when it hits the car's dashboard. Also assume that the mass of the body parts stopped by the knee is about 20% of the total body mass. (a) What minimum stopping time interval is needed to avoid injury to the knee if the person is initially traveling at 15 m/s (34 mi/h)? (b) What is the minimum stopping distance?
46. * BIO **Bone fracture** The zygomatic bone in the upper part of the cheek can be fractured by a 900-N force lasting 6.0 ms or longer. A hockey puck can easily exert such a force when hitting an unprotected face. (a) What change in velocity of a 0.17-kg hockey puck is needed to provide that impulsive force? What assumptions did you make? (b) A padded facemask doubles the stopping time. By how much does it change the force on the face? Explain.
47. ** You are investigating a newly discovered particle X that has an unknown mass M and moves with a constant but unknown speed u. In your experiments you observe collisions between particle X and different test particles with known masses m that are initially at rest. You let the particles collide head-on and stick together, and you measure the speed v of the combined-particle object. From other observations you know that in all experiments the objects move along the same straight line before and after the collision. Your data are shown in the table at right. Note that the masses are expressed in units of reference mass m_0 and the speed in units of reference speed v_0. (a) Derive an expression for v in terms of M, m, and u. Indicate any assumptions that you made. (b) Determine M and u using the data in the table. (Hint: Rearrange the expression that you derived in (a) to obtain a new equation with the linear dependence on m.)

$m\ (m_0)$	$v\ (v_0)$
2.0	0.55
4.0	0.45
6.0	0.35
8.0	0.30
10.0	0.25

48. * An impulse of 150 N · s stops your head during a car collision. (a) A crash test dummy's head stops in 0.020 s, when the cheekbone hits the steering wheel. What is the average force that the wheel exerts on the dummy's cheekbone? (b) Would this crash fracture a human cheekbone (see Problem 6.46)? (c) What is the shortest impact time that a person could sustain without breaking the bone?
49. A cart is moving on a horizontal track when a heavy bag falls vertically onto it. What happens to the speed of the cart? Represent the process with an impulse-momentum bar chart. Justify your choice of a system.
50. * A cart is moving on a horizontal track. A heavy bag falls off the cart and moves straight down relative to the cart. Describe what happens to the speed of the cart. Represent your answer with the impulse-momentum bar chart. Justify your choice of a system. (Hint: What reference frame will you use when you draw the bar chart?)
51. Your friend shoots an 80-g arrow through a 100-g apple balanced on William Tell's head. The arrow has a speed of 50 m/s before passing through the apple and 40 m/s after. Determine the final speed of the apple.

6.6 Jet propulsion

52. * BIO EST Cuttlefish use jet propulsion to move rapidly. To do this, a cuttlefish fills its muscular mantle cavity with water and then quickly expels the water through a tube-like opening. The mass of a cuttlefish is about the same as the mass of water of the same volume. A 15-cm-long and 5-cm-wide cuttlefish is moving at a speed of 3 m/s after expelling the water from its body. Estimate the speed of the expelled water relative to the sea bed. Indicate any assumptions that you made.

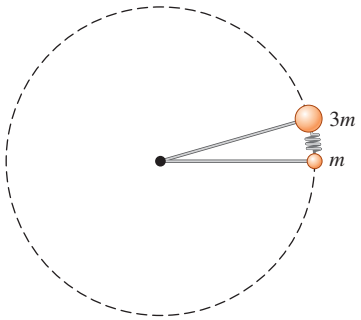


53. * BIO **Potassium decay in body tissue** Certain natural forms of potassium have nuclei that are radioactive. Each radioactive potassium nucleus decays to a slightly less massive daughter nucleus and a high-speed electron called a beta particle. If after the decay the daughter nucleus is moving at speed 200 m/s with respect to the decaying material, how fast is the electron (the beta particle) moving? Indicate any assumptions you made. The mass of the daughter nucleus is about 70,000 times greater than the mass of the beta particle.
54. **Drifting space mechanic** An astronaut with a mass of 90 kg (including spacesuit and equipment) is drifting away from his spaceship at a speed of 0.20 m/s with respect to the spaceship. The astronaut is equipped only with a 0.50-kg wrench to help him get back to the ship. With what speed and in what direction relative to the spaceship must he throw the wrench for his body to acquire a speed of 0.10 m/s and direct him back toward the spaceship? Explain.
55. * **Astronaut flings oxygen tank** While the astronaut in Problem 6.54 is trying to get back to the spaceship, his comrade, a 60-kg astronaut, is floating at rest a distance of 10 m from the spaceship when she runs out of oxygen and fuel to power her back to the spaceship. She removes her oxygen tank (3.0 kg) and flings it away from the ship at a speed of 15 m/s relative to the ship. (a) At what speed relative to the ship does she recoil toward the spaceship? (b) How long must she hold her breath before reaching the ship?
56. **Rocket stages** A 5000-kg rocket ejects a 10,000-kg package of fuel. Before ejection, the rocket and the fuel travel together at a speed of 200 m/s with respect to distant stars. If after the ejection, the fuel package travels at 50 m/s opposite the direction of its initial motion, what is the velocity of the rocket?
57. * A rocket has just ejected fuel. With the fuel and the rocket as the system, construct an impulse-momentum bar chart for (a) the rocket's increase in speed and (b) the process of a rocket slowing down due to fuel ejection. (c) Finally, draw bar charts for both situations using the rocket without the fuel as the system.

6.7 Collisions in two dimensions

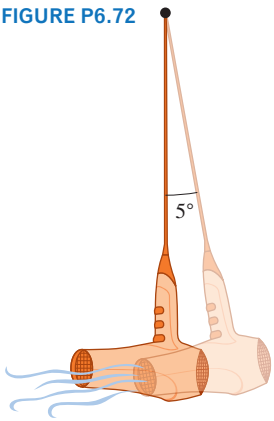
58. * **Car collision** A 1180-kg car traveling south at 24 m/s with respect to the ground collides with and attaches to a 2470-kg delivery truck traveling east at 16 m/s. Determine the velocity (magnitude and direction) of the two vehicles when locked together just after the collision.
59. * **Ice skaters collide** While ice skating, you unintentionally crash into a person. Your mass is 60 kg, and you are traveling east at 8.0 m/s with respect to the ice. The mass of the other person is 80 kg, and he is traveling north at 9.0 m/s with respect to the ice. You hang on to each other after the collision. In what direction and at what speed are you traveling just after the collision?
60. ** EST **Meteorite impact with Earth** About 65 million years ago a 10-km-diameter 2×10^{15}-kg meteorite traveling at about 10 km/s crashed into what is now the Gulf of Mexico. The impact produced a cloud of debris that darkened Earth and led to the extinction of the dinosaurs. Estimate the change of the Earth's speed as a result of this impact and the average force that the meteorite exerted on Earth during the collision. Indicate any assumptions made in your calculations.
61. * Three friends play beach volleyball. The 280-g ball is flying east at speed 8.0 m/s with respect to the ground when one of the players bumps the ball north. The force exerted by the wrist on the ball has an average magnitude of 84 N and lasts for 0.010 s. Determine the ball's velocity (magnitude and direction) following the bump. Does your answer make sense?
62. ** Two forces exert impulses on a hockey puck, which can move with no friction on an icy surface. The graphs at left in **Figure P6.62** show the time dependence of the *x*- and *y*-components of the sum of the forces exerted on the puck. Which of the trajectories (a) to (d) of the puck's motion in the *xy*-plane shown at right in Figure P6.62 *cannot* be the result of these forces? The numbers correspond to successive clock readings that are marked on the force graphs.

FIGURE P6.62



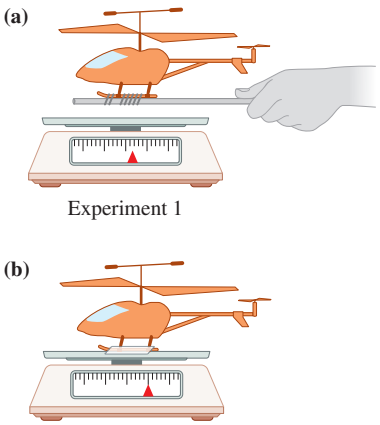
General Problems

63. ** EST Estimate the recoil speed of Earth if all of the inhabitants of Canada and the United States simultaneously jumped straight upward from Earth's surface (reaching heights from several centimeters to a meter or more). Indicate any assumptions that you made in your estimate.
64. * A cart of mass *m* traveling in the negative *x*-direction at speed *v* collides head-on with a cart that has triple the mass and is moving at 60% of the speed of the first cart. The carts stick together after the collision. In which direction and at what speed will they move?
65. ** Two cars of unequal mass moving at the same speed collide head-on. Explain why a passenger in the smaller mass car is more likely to be injured than one in the larger mass car. Justify your reasoning with the help of physics principles.
66. ** **Restraining force during collision** A 1340-kg car traveling east at 13.6 m/s (30 mi/h) has a head-on collision with a 1930-kg car traveling west at 20.5 m/s (46 mi/h). If the collision time is 0.10 s, what is the force needed to restrain a 68-kg person in the smaller car? In the larger car?
67. * EST A carpenter hammers a nail using a 0.80-kg hammerhead. He lifts the hammer and lets it fall down without exerting an additional force on the hammer. After the hammer hits the nail, they move together for 0.005 s until they stop. (a) Estimate the speed of the hammerhead before it hits the nail. (b) Estimate the average force that the hammerhead exerts on the nail. Indicate any assumptions that you made.



68. ** A 0.020-kg bullet traveling at a speed of 300 m/s embeds in a 1.0-kg wooden block resting on a horizontal surface. The block slides horizontally 4.0 m on a surface before stopping. Determine the coefficient of kinetic friction between the block and surface.
69. * Two identical lightweight arms are mounted so that they can revolve in a horizontal plane around a common axis. Two balls of masses m and $3m$ are fixed to the ends of the arms and connected with a light compressed spring (see the top view in **Figure P6.69**). When the spring is released, the arms are pushed apart, rotate in opposite directions, and finally collide. What is the angle through which each arm turns before they collide? Indicate any assumptions that you made.

FIGURE P6.69



70. * In a first experiment, a 30-g clay ball is shot at a speed of 1.3 m/s horizontally from the edge of a table. The ball lands on the floor 0.60 m from the table. In a second experiment, the same ball is shot at the same speed, but this time the ball hits a wooden block that is placed on the edge of the table. The ball sticks to the block, and the block lands on the floor 0.06 m from the table. (a) Represent the second experiment with impulse-momentum bar charts, treating the x- and y-components separately; draw two sets of bar charts, first taking the wooden block as a system and then taking the block and the clay ball as a system (initial state: just before the clay ball hits the block; final state: just before the block touches the floor). Determine (b) the mass of the block and (c) the height of the table. Indicate any assumptions that you made.
71. ** EST A record rainstorm produced 304.8 mm (approximately 1 ft) of rain in 42 min. Estimate the average force that the rain exerted on the roof of a house that measures 10 m × 16 m. Indicate any assumptions you made.
72. * While dangling a hairdryer by its cord, as shown in **Figure P6.72**, you observe that the cord is vertical when the hairdryer is off and that it makes an angle of 5° with the vertical when the hairdryer is turned on. Draw a force diagram for the hairdryer in both cases and explain the outcome of the experiment using momentum arguments.

FIGURE P6.72

73. ** While dangling a hairdryer by its cord, as shown in Figure P6.72, you observe that the cord is vertical when the hairdryer is off and that it makes an angle of 5° with the vertical when the hairdryer is turned on. In a different experiment, you determine that the same hairdryer is pushing 0.03 m^3 of air through itself every second. The mass of the hairdryer is 420 g. Determine the speed of the air that is leaving the hairdryer, assuming that the mass of 1 m^3 of air is 1.2 kg and that the hairdryer is blowing air perpendicular to the wire.
74. ** Martha learns that a helicopter is able to lift or hover by pushing air downward, resulting in air pushing up on the helicopter blades. She decides to investigate this mechanism using her remote-controlled toy helicopter. In her first experiment, she fixes the helicopter on a long stick, holds it directly above the plate of a scale (without touching the scale), and lets the blades rotate with maximum speed (see **Figure P6.74a**). The scale reading is zero before she switches the helicopter on and 54 g when the blades are rotating. In her second experiment, she fixes the helicopter legs to the scale plate using Scotch tape and again lets the blades rotate with maximum speed (see Figure P6.74b). The scale reading shows the mass of the helicopter as 123 g before the blades are rotating and 134 g when the blades are rotating. (a) Explain why the scale shows a nonzero reading in the first experiment even though the helicopter is not touching the scale. (b) Martha is surprised that, in the second experiment, the scale reading does not decrease when the blades start rotating—indeed, the reading *increases*. Why did Martha expect the reading to decrease? Explain the increase of the scale reading after the blades start rotating. (Note that the increase is much smaller than the increase in the first experiment.)

FIGURE P6.74

75. * A 2045-kg sports utility vehicle hits the rear end of a 1220-kg car at rest at a stop sign. The car and SUV remain locked together and skid 4.6 m before stopping. If the coefficient of friction between the vehicles and the road is 0.70, what was the SUV's initial velocity?
76. ** A car of mass m_1 traveling north at a speed of v_1 collides with a car of mass m_2 traveling east at a speed of v_2. They lock together after the collision. Develop expressions for the direction and the distance the cars will move until they stop if the coefficient of kinetic friction μ_k between the cars' tires and the road is about the same for both cars.
77. * **Write your own problem** Write and solve a problem that requires using the law of conservation of momentum in which it is important to know that momentum is a vector quantity.
78. ** You have two carts, a force probe connected to a computer, a motion detector, and an assortment of objects of different masses. Design three experiments to test whether momentum is a conserved quantity. Describe carefully what data you will collect and how you will analyze the data.

Reading Passage Problems

BIO **Heartbeat detector** A prisoner tries to escape from a Nashville, Tennessee prison by hiding in the laundry truck. The prisoner is surprised when the truck is stopped at the gate. A guard enters the truck and handcuffs him. "How did you know I was here?" the prisoner asks. "The heartbeat detector," says the guard.

A heartbeat detector senses the tiny vibrations caused by blood pumped from the heart. With each heartbeat, blood is pumped upward to the aorta, and the body recoils slightly, conserving the momentum of the blood-body system. The body's vibrations are transferred to the inside of the truck. Vibration sensors on the outside of the truck are linked to a geophone, or signal amplifier, attached to a computer. A wave analyzer program in the computer compares vibration signals from the truck to wavelets produced by heartbeat vibrations. The wave analyzer distinguishes a person's heartbeat from other vibrations in the truck or in the surrounding environment, allowing guards to detect the presence of a human in the truck.

79. What does the heartbeat detector sense?
    (a) Electric signals caused by electric dipole charges produced on the heart
    (b) Body vibrations caused by blood pumped from the heart
    (c) Sound caused by breathing
    (d) Slight uncontrollable reflexive motions of an enclosed person
    (e) All of the above
80. A heartbeat detector relies on a geophone placed against the exterior of a truck or car. What can cause the vibrations of the truck or car?
    (a) Wind
    (b) Ground vibrations due to other moving cars or trucks
    (c) Vibrations of passengers in the car or truck
    (d) All of the above
81. What can be used to analyze the motion of a person's body hidden inside a car or truck (choosing the body and blood as a system)?
    (a) The idea that mass of an isolated system is constant
    (b) The idea that momentum of an isolated system is constant
    (c) The impulse-momentum principle
    (d) a and b
    (e) b and c
82. During each heartbeat, about 0.080 kg of blood passes through the aorta in about 0.16 s. This blood's velocity changes from about 0.8 m/s upward toward the head to 0.8 m/s down toward the feet. What is the blood's acceleration?
    (a) zero (b) $5\ \text{m/s}^2$ up (c) $5\ \text{m/s}^2$ down
    (d) $10\ \text{m/s}^2$ up (e) $10\ \text{m/s}^2$ down
83. Suppose 0.080 kg of blood moving upward in the aorta at 0.8 m/s reverses direction in 0.16 s when it reaches the aortic arch. If a prisoner is trying to escape from prison by hiding in a laundry truck, and the mass of his body is 70 kg, which is the closest to the speed his body is moving immediately after the blood changes direction passing through the aortic arch?
    (a) 0.0009 m/s (b) 0.002 m/s (c) 0.8 m/s
    (d) 0.08 m/s (e) 0.01 m/s

Space Shuttle launch The mass of the Space Shuttle at launch was about 2.1×10^6 kg. Much of this mass was the fuel used to move the orbiter, which carried the astronauts and various items in the shuttle's payload. The Space Shuttle generally traveled from 3.2×10^5 m (200 mi) to 6.2×10^5 m (385 mi) above Earth's surface. The shuttle's two solid fuel boosters (the cylinders on the sides of the shuttle) provided 71.4% of the thrust during liftoff and the first stage of ascent before being released from the shuttle 132 s after launch at 48,000 m above sea level. The boosters continued moving up in free fall to an altitude of approximately 70,000 m and then fell toward the ocean to be recovered 230 km from the launch site. The shuttle's five engines together provided 3.46×10^7 N of thrust during liftoff.

84. Which number below is closest to the acceleration of the shuttle during liftoff? (Hint: Remember the gravitational force that Earth exerts on the shuttle.)
    (a) $3.3\ \text{m/s}^2$ (b) $6.6\ \text{m/s}^2$ (c) $9.8\ \text{m/s}^2$
    (d) $16\ \text{m/s}^2$ (e) $33\ \text{m/s}^2$
85. Which number below is closest to the average vertical acceleration of the shuttle during the first 132 s of its flight?
    (a) $3.3\ \text{m/s}^2$ (b) $5.5\ \text{m/s}^2$ (c) $9.8\ \text{m/s}^2$
    (d) $14\ \text{m/s}^2$ (e) $360\ \text{m/s}^2$
86. The boosters were released from the shuttle 132 s after launch. How did their vertical components of velocity compare to that of the shuttle at the instant of release?
    (a) The boosters' vertical component of velocity is zero.
    (b) The boosters' vertical component of velocity is about -9.8 m/s.
    (c) The vertical component of velocity of the boosters and that of the shuttle are the same.
    (d) There is too little information to decide.
87. What was the approximate impulse of the jet engine thrust exerted on the shuttle during the first 10 s of flight?
    (a) $980\ \text{N} \cdot \text{s}$ downward (b) $980\ \text{N} \cdot \text{s}$ upward
    (c) $3.4 \times 10^7\ \text{N} \cdot \text{s}$ upward (d) $3.4 \times 10^8\ \text{N} \cdot \text{s}$ upward
    (e) $3.4 \times 10^8\ \text{N} \cdot \text{s}$ downward
88. What was the approximate impulse of Earth's gravitational force exerted on the shuttle during the first 10 s of flight?
    (a) $980\ \text{N} \cdot \text{s}$ downward (b) $980\ \text{N} \cdot \text{s}$ upward
    (c) $2.1 \times 10^7\ \text{N} \cdot \text{s}$ upward (d) $2.1 \times 10^8\ \text{N} \cdot \text{s}$ upward
    (e) $2.1 \times 10^8\ \text{N} \cdot \text{s}$ downward
89. What was the momentum of the Space Shuttle 10 s after liftoff closest to?
    (a) $2.1 \times 10^6\ \text{kg} \cdot \text{m/s}$ down (b) $2.1 \times 10^6\ \text{kg} \cdot \text{m/s}$ up
    (c) $2.1 \times 10^7\ \text{kg} \cdot \text{m/s}$ up (d) $1.3 \times 10^8\ \text{kg} \cdot \text{m/s}$ up
    (e) $1.3 \times 10^8\ \text{kg} \cdot \text{m/s}$ down
90. What answer below is closest to the speed of the shuttle and boosters when they were released? Assume that the free-fall gravitational acceleration at this elevation is about $9.6\ \text{m/s}^2$ down.
    (a) 100 m/s (b) 300 m/s (c) 600 m/s
    (d) 1000 m/s (e) 1400 m/s

7

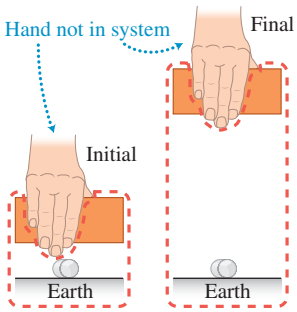
Work and Energy

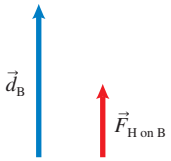
- **How do pole vaulters reach a height of 5 or 6 m?**
- **Why does blood pressure increase when the walls of the aorta thicken?**
- **If our Sun were to become a black hole, how big would it be?**

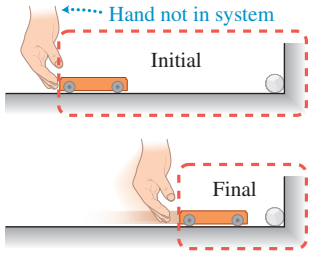
Yelena Isinbayeva from Russia has held the women's pole-vaulting record of 5.06 m since 2009. The men's record is 6.16 m. How can pole vaulters reach such great heights? If you watch the event, you will see three aspects of the vault that are essential: the vaulters run very fast before inserting the pole into the vaulting box; they jump at the moment of takeoff while bending the pole as they start their vertical ascent; and they crunch their muscles at the top of the flight to give a specific body shape as they pass over the bar. All these elements contribute to the height of the vault—in this chapter, we will learn how.

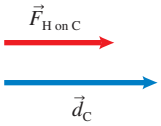
BE SURE YOU KNOW HOW TO:

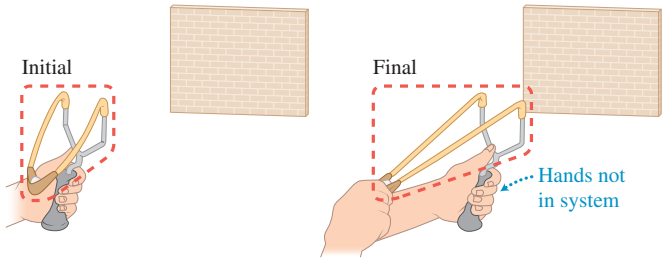
- Choose a system and the initial and final states of a physical process (Sections 6.2–6.4).
- Use Newton's second law and your knowledge of momentum to analyze a physical process (Sections 4.4 and 6.4).
- Use kinematics to describe motion (Section 2.9).

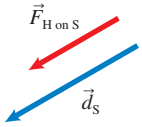


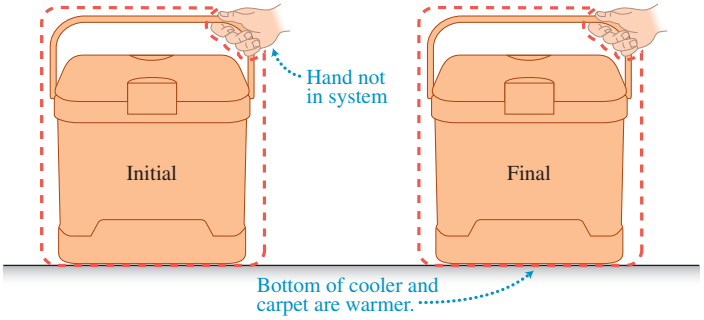


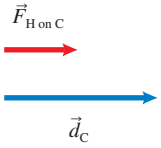












SO FAR, WE HAVE learned how to use forces and momentum to explain and analyze different types of motion. However, not all questions concerning motion can be answered using these concepts. For example, imagine a roller coaster in an amusement park. It has no engine or battery, but it goes through multiple loops and many twists and turns. The force that the track exerts on it continuously changes direction and magnitude. How is it possible to design the track so the coaster will make it through the entire ride without falling or grinding to a halt? It turns out that there are several important physical quantities, and a new principle, that are important in designing a roller coaster. We will learn about these quantities and this principle in this chapter.

7.1 Work and energy

We will begin our new approach by conducting several experiments and looking for patterns to help explain what we observe. Specifically, in Observational Experiment **Table 7.1** we investigate the changes that happen to a system when an external force is exerted on it over a certain distance. In the analysis we draw vectors indicating the external force causing the displacement and the resulting displacement of the system.

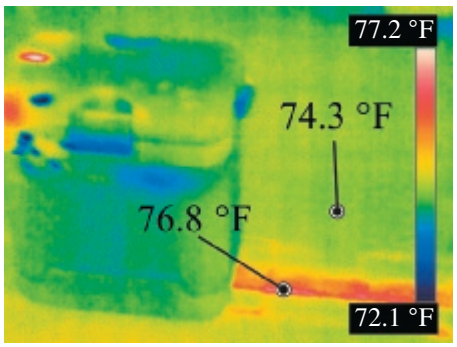
OBSERVATIONAL EXPERIMENT TABLE 7.1 External forces and system changes

VIDEO OET 7.1

Observational experiment	Analysis
Experiment 1. You hold a heavy block just above a piece of chalk (the initial state) and then release the block. The chalk does not break. Now you lift the block about 30 cm above the chalk (the final state). When you release the block from the higher elevation, the block falls and smashes the chalk. 	The force you exerted and the block's displacement while being lifted were in the same direction and caused an increase in the block's elevation and in its ability to break the chalk. 
Experiment 2. You push a cart initially at rest (the initial state) until it is moving fast about two-thirds of the way across a smooth track (the final state is where you stop pushing the cart). A piece of chalk is taped to the end of the track. The fast-moving cart (no longer being pushed) collides with the piece of chalk and breaks the chalk. When you repeat the experiment with a slow-moving cart, it does not break the chalk. 	The force exerted on the cart and the cart's displacement were in the same direction and increased the cart's speed so it could break the chalk. 
Experiment 3. A piece of chalk rests in the hanging sling of a slingshot (the initial state). You then pull it back until the slingshot is fully stretched (the final state). When released from the stretched sling, the chalk flies across the room, hits the wall, and smashes. 	The force that you exerted on the sling and its displacement were in the same direction and made it possible for the stretched sling to cause the chalk to break. 
Experiment 4. A heavy cooler sits on a shag carpet (the initial state). You pull the cooler across the carpet to a position several meters from where it started (the final state). 	You exerted a force on the cooler in the direction of its displacement. After several meters of travel across the carpet, the bottom became warmer. 

(CONTINUED)

Patterns



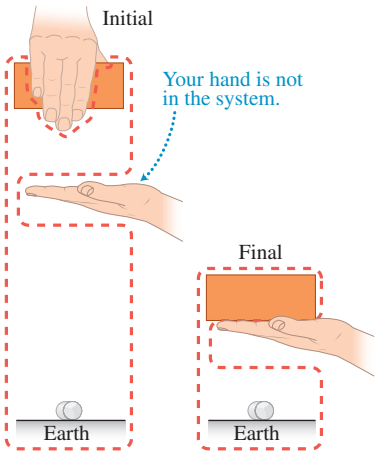
In each of these experiments, you exerted an external force $\vec{F}$ on an object in a system. The force $\vec{F}_{\text{You on Object}}$ and the object's displacement $\vec{d}_{\text{Object}}$ were in the *same direction* and caused the system to change so that it could do something that it could not do before, such as break the chalk or warm up the carpet. Specifically:

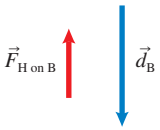
1. The *block at higher elevation* above Earth could break the chalk, but the block at low elevation could not.
2. The *fast-moving cart* could break the chalk, but the slow-moving cart could not.
3. The *stretched slingshot* could break the chalk, but the unstretched slingshot could not.
4. The *cooler and the carpet it was pulled across* became warmer than they were before the cooler was pulled across the carpet.

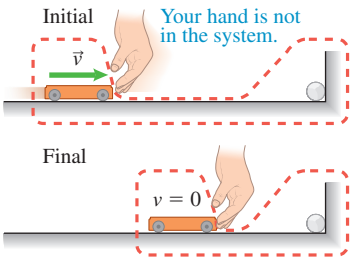
In the experiments in Table 7.1, the system could not break the chalk or warm the carpet in the initial state, but in the final state it could. What happened to each system to cause that change? In all cases, **an external force exerted on the system caused a displacement of an object in the system in the *same direction* as the force.** Using everyday words in a very specific way, physicists say that such a force does positive **work** on a system, and that this work done causes a change in what is called the system's **energy** (we will learn later that there can be negative work that also changes the system's energy). Energy is rather difficult to define at this point, but you can think of it loosely as a property of a system that changes when work is done on the system. Four types of energy changed in the systems in Table 7.1:

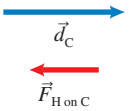
- Experiment 1: The energy of the object-Earth system associated with the elevation of the object above Earth is called **gravitational potential energy** U_g. The higher the object is above Earth, the greater the gravitational potential energy of that object-Earth system.
- Experiment 2: The energy due to an object's motion is called **kinetic energy** K. The faster the object is moving, the greater its kinetic energy.
- Experiment 3: The energy associated with an elastic object's degree of stretch is called **elastic potential energy** U_s. The greater the stretch (or compression), the greater the object's elastic potential energy.
- Experiment 4: The energy associated with both temperature and structure is called **internal energy** U_{int}. You will learn later that internal energy is the energy of motion and interaction of the microscopic particles making up the objects in the system. A component of internal energy is **thermal energy**, energy associated with the temperature of the objects in the system (see the photo). In this chapter, when we apply the concept of internal energy to people, we will also talk about muscles' **chemical energy**—this is another component of internal energy related to the interaction of particles in chemical compounds.

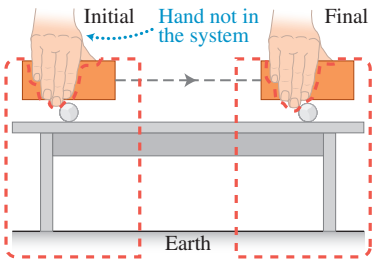
A photo of the carpet and cooler in Experiment 4 from Table 7.1 taken with a thermal camera. The temperature of the carpet and the cooler increases by about 2.5 °F. This shows the change in the thermal energy of both objects.

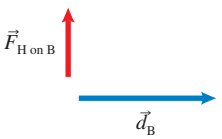












Negative and zero work

Is it possible to devise a process in which an external force causes the energy of a system to decrease or possibly causes no energy change at all? Let's try more experiments to investigate these questions. See Observational Experiment **Table 7.2** on the next page.

OBSERVATIONAL EXPERIMENT TABLE 7.2 Negative and zero work

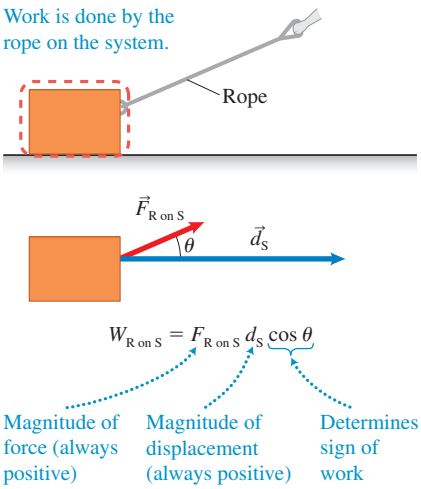
VIDEO OET 7.2

Observational experiment	Analysis
Experiment 1. A friend holds a block high above a piece of chalk (the initial state) and then releases it. Your hand catches and stops the block (the final state). The block's potential to break the chalk is greater in the initial state than in the final state. 	The direction of the force exerted by your hand on the block is opposite the block's displacement and reduced the system's potential to break the chalk. 
Experiment 2. A cart is moving fast (the initial state) toward a piece of chalk taped on the wall. While it is moving, you push lightly on the moving cart opposite the direction of its motion, causing it to slow down and stop (final state). The cart's potential to break the chalk is greater in the initial state than in the final state. 	The direction of the force exerted by your hand on the cart is opposite the cart's displacement and caused the moving cart to slow down and stop, thus reducing its potential to break the chalk. 
Experiment 3. Your hand is slowly moving a block to the right, keeping the block just above the tabletop. The block passes above the piece of chalk on the left (initial state) and then over the piece of chalk on the right (final state). The block is too close to the chalk in both states to break it. 	The direction of the force exerted by your hand on the block is perpendicular to the block's displacement and caused no change in the block's potential to break the chalk. 

Patterns

- In Experiments 1 and 2, the direction of the external force exerted on the object in the system is opposite the object's displacement, and the system's ability to break the chalk decreases.
- In Experiment 3, the direction of the external force exerted on the object in the system is perpendicular to the object's displacement, and the system's ability to break the chalk is unchanged.

We can now summarize what we have learned about work:



- When the external force is in the direction of the object's displacement, the external force does *positive work,* causing the system to gain energy.
- When the external force points opposite the object's displacement, the external force does *negative work,* causing the system's energy to decrease.
- When the external force points perpendicular to the object's displacement, the external force does *zero work* on the system, causing no change to its energy.

Defining work as a physical quantity

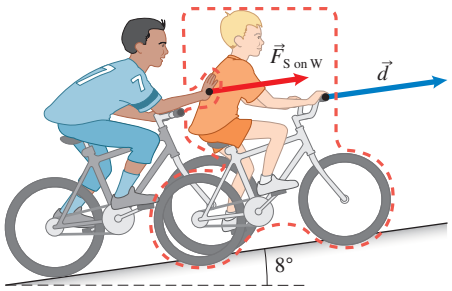
We now want to find a mathematical relation to define the physical quantity of work. The definition needs to be consistent with all three of the features of work listed in the previous section. Intuitively, we know that a larger force should lead to larger work, as should a larger displacement. But how do we account for the angle dependence? It turns out that there is a mathematical function that will take care of this issue—the cosine of the angle between the direction of the force vector and displacement vector (this angle is θ in **Figure 7.1**).

Note that in the four experiments in Table 7.1, the force and displacement were in the same direction: $\theta = 0°$, and $\cos 0° = +1.0$. Positive work was done. In the first two experiments in Table 7.2, the force and displacement were in opposite directions: $\theta = 180°$, and $\cos 180° = -1.0$. Negative work was done. Finally, in Experiment 3 in Table 7.2, the force and displacement were perpendicular to each other: $\theta = 90°$, and $\cos 90° = 0$. Zero work was done.

FIGURE 7.1 The definition of work.

Work The work done by a constant external force $\vec{F}$ exerted on an object in a system while that object undergoes a displacement $\vec{d}$ is

$$W = Fd\cos\theta \tag{7.1}$$



where F is the magnitude of the force in newtons (always positive), d is the magnitude of the displacement in meters (always positive), and θ is the angle between the direction of $\vec{F}$ and the direction of $\vec{d}$. The sign of $\cos\theta$ determines the sign of the work. Work is a scalar physical quantity. The unit of work is the joule (J); $1\ \text{J} = 1\ \text{N}\cdot\text{m}$.

The joule is named in honor of James Joule (1818–1889), one of many physicists who contributed to our understanding of work-energy relationships.

According to the definition of work, if the displacement of an object is zero, even if forces are exerted on it, no work is done. This idea might contradict your everyday experience. Imagine holding a heavy object (for example, a suitcase) in a steady position. The system is the suitcase and Earth; you are an external object. If the suitcase remains at rest, the work done by the force you exert on it is zero. But you still get tired. How is this possible? It turns out that even when you are holding something still, your muscles still contract and relax all the time, making your arm go up and down slightly (we cannot see this movement with the naked eye, but scientists use a special method called *sound myography* to detect such muscle contractions). Thus you are doing work on the suitcase by continuously lifting it a little and then dropping it, repeating the process many times. Let us now include you in the system. Careful observations show that while holding the suitcase, you breathe a little faster and small drops of perspiration appear on your face. These are the signs of increased metabolic activity—your chemical energy is converted into the kinetic and elastic potential energy of your muscles and also into thermal energy. Thus there is no contradiction between physics and everyday life.

QUANTITATIVE EXERCISE 7.1 **Pushing a bicycle uphill**

Two friends are cycling up a hill inclined at 8°—steep for bicycle riding. The stronger cyclist helps his friend up the hill by exerting a 50-N pushing force on his friend's bicycle and parallel to the hill while the friend moves a distance of 100 m up the hill. Determine the work done by the stronger cyclist on the weaker cyclist.

Represent mathematically Choose the system to be the weaker cyclist. The external force that the stronger cyclist (S) exerts on the weaker cyclist (W) $\vec{F}_{\text{S on W}}$ is parallel to the hill, as is the 100-m displacement of the weaker cyclist. The work done by the stronger cyclist on the weaker cyclist is $W = Fd\cos\theta$. The hill is inclined at 8° above the horizontal. Before reading on, decide what angle you would insert in this equation.

Solve and evaluate Note that the angle between $\vec{F}_{\text{S on W}}$ and $\vec{d}$ is 0° and not 8° because the force exerted on the cyclist is parallel to the person's displacement. Thus:

$$W_{\text{S on W}} = F_{\text{S on W}}d\cos\theta = (50\text{ N})(100\text{ m})\cos 0° = +5000\text{ N}\cdot\text{m} = +5000\text{ J}$$

Try it yourself You pull a box 20 m up a 10° ramp. The rope is oriented 20° above the surface of the ramp. The force that the rope exerts on the box is 100 N. What is the work done by the rope on the ramp itself?

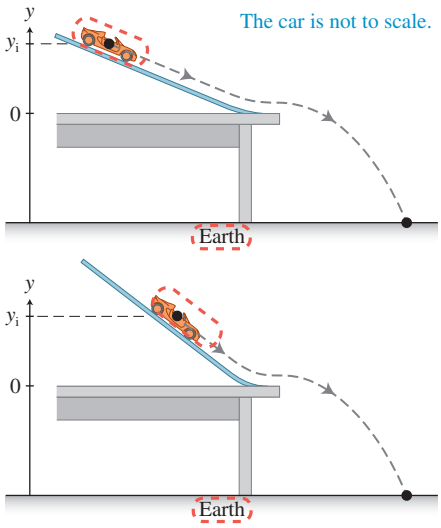
Answer

$W_{\text{R on B}} = (100\text{ N})(20\text{ m})\cos 20° = 1900\text{ J}$. Note that you use the angle between the displacement (parallel to the ramp) and the force the rope exerts on the box (20° above the ramp). You can disregard the angle of the ramp itself.

REVIEW QUESTION 7.1 Assuming that Earth's orbit around the Sun is circular, what information do you need to estimate the work done by the Sun on Earth while Earth travels 1000 km? Explain your answer.

7.2 Energy is a conserved quantity

We have found that the work done on an object in a system by an external force results in a change of one or more types of energy in the system: kinetic energy, gravitational potential energy, elastic potential energy, and internal energy. We can think of the *total energy* E of a system as the sum of all these energies in the system:



$$\text{Total energy} = E = K + U_g + U_s + U_{\text{int}} \tag{7.2}$$

The energy of a system can be converted from one form to another. For example, the elastic potential energy of a stretched slingshot is converted into the kinetic energy of the chalk when the sling is released. Similarly, the gravitational potential energy of a separated block-Earth system is converted into kinetic energy of the block when the block falls. Here we assume that Earth does not move when the block moves toward it. What happens to the amount of energy when it is converted from one form to another? So far we have one mechanism through which the energy of the system changes—that mechanism is work. Thus it is reasonable to assume that if no work is done on the system, the energy of the system should not change; it should be *constant*. Let's test this hypothesis experimentally (see Testing Experiment **Table 7.3**, on the next page).

TIP Remember that an *isolated* system is a system for which we can neglect interactions with the environment. Thus, when external objects do zero work on a system, the system can be considered isolated.

TESTING
EXPERIMENT TABLE 7.3  Is the energy of an isolated system constant?

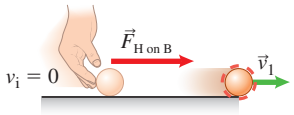
VIDEO TET 7.3

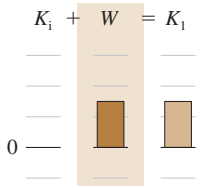
Testing experiment	Prediction	Outcome
You have a toy car and a frictionless track. The bottom of the track sits near the edge of a table. You can tilt the track at different angles to vary its steepness. When the car reaches the end of the track, it flies horizontally off the table. Where should you release a car on the track so the car always lands the same distance from the table regardless of the slope of the track? 	Consider car + Earth as the system. The initial state is just before we release the car and the final state is just as the car leaves the horizontal track. For the car to land on the floor at the same distance from the table's edge, the car needs to have the same horizontal velocity and hence the same kinetic energy when leaving the track. If energy is constant in the isolated system, to get the same kinetic energy at the bottom of the track, the car-Earth system must have the same initial gravitational energy when it starts. Since the gravitational potential energy depends on the separation between the car and Earth, the car should start at the same vertical elevation independent of the tilt angle of the track, $y_i = h$. Our prediction is based on the assumption that the gravitational potential energy of the system is only converted to the kinetic energy of the car and not to internal energy.	When released from the same vertical height with respect to the table, the car lands the same distance from the table.

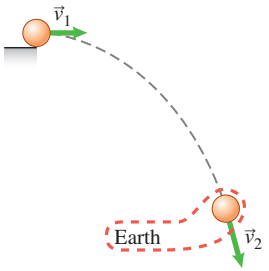
Conclusion

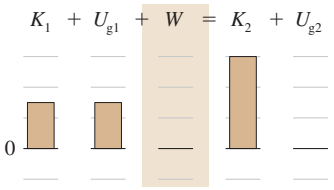
The outcome of the experiment matches the prediction and thus supports our hypothesis that the energy of an isolated system is constant.

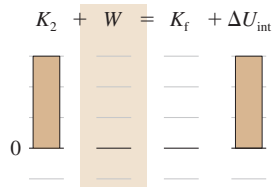
TIP It is important to note that in the above arguments we assumed that Earth is infinitely large and does not move when an object falls down or flies up.











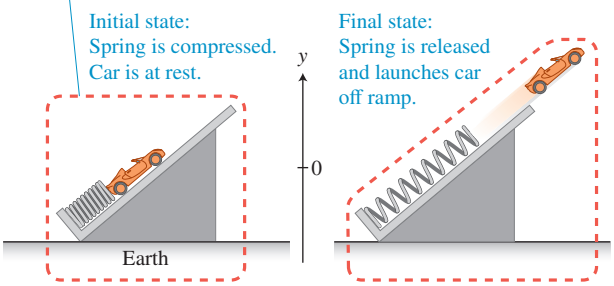
So far we have experimental support for a qualitative hypothesis that the energy of an isolated system is constant and different processes inside the system convert energy from one form to another. We also reason that work is a mechanism through which the energy of a nonisolated system changes. This sounds a lot like our discussion of linear momentum (Chapter 6). In that chapter, we described a *conserved quantity* as one that is constant in an isolated system. We also said that when the system is not isolated and the conserved quantity changes, we can always redefine the system in such a way as to keep the quantity constant. Imagine that we did not include Earth in the system in the experiment above. We would find that the energy of the cart (our new system) changed during the experiment because it acquired kinetic energy moving down the track due to the work done by Earth on it. Thus the energy of the cart as a system was not constant. However, when we include Earth in the system, the energy remains constant.

Work-energy bar charts

We can represent work-energy processes with bar charts that are similar to the impulse-momentum bar charts we used to describe momentum. A work-energy bar chart indicates with vertical bars the relative amount of a system's different types of energy in the initial state of a process, the work done on the system by external forces during the process, and the relative amount of different types of energy in the system at the end of the process. The area for the work bar is shaded to emphasize that work is not a property of the system. The physical quantity of work characterizes the process

through which energy is transferred in or out of the system due to the external forces that cause displacements of the objects inside the system. In terms of system change, work is similar to impulse in our study of momentum. In **Table 7.4** you see how bar charts can be used to represent the process when you push a clay ball off a frictionless table exerting a constant force (situation 1), the ball flies off the table (situation 2), and lands on the floor and stops (situation 3). We break the process into three parts and explain how we choose the system in each situation.

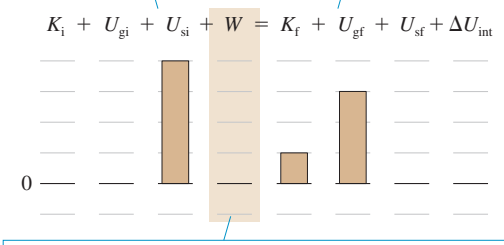
TABLE 7.4 Examples of system energy conversions



Process	Sketch of initial and final states and explanations of the system choice	Bar chart for the process
1. You push a clay ball along a frictionless table, exerting a constant force.	Initial state: The ball is at rest. Final state: The ball is moving and is just about to leave the table. System: The ball. We choose the ball as the system because there is no elevation change, thus we do not need to worry about gravitational potential energy. 	Your hand does positive work on the system. The ball gains kinetic energy. 
2. The clay ball falls down freely off the edge of the table.	Initial state: The ball is at the top of its flight. Final state: Just before the ball hits the floor (it is still moving). System: The ball and Earth. We included Earth in the system because there is elevation change and thus a change in gravitational potential energy. If we did not include Earth in the system, it would do work but there would be no gravitational potential energy in any state. 	No work is done on the system. The system's initial gravitational potential energy is converted into kinetic energy. We assume that the gravitational potential energy of the system at floor level is zero, so there is no bar for U_{gf}. 
3. The clay ball lands on the floor and stops.	Initial state: Just before the moving ball hits the floor. Final state: Just after the ball stops (and its shape changes). System: The ball and the floor. The floor stopped the ball during landing, but it did not move; thus it would be difficult to account for the effects of the floor via work. Including it in the system removes the need to account for work done by the floor. Earth is not included in the system because the elevation did not change in this situation. 	No work is done on the system. The ball's kinetic energy is converted into internal energy of the ball and the floor. 

From the examples in the table you can conclude that when choosing what objects to include in the system and what not to include, we can use the following approach: **If it is difficult to calculate the work done by that object on the system, we are usually better off including it in the system so that we describe the processes using different forms of energy.** As you proceed through the chapter you will see more examples and discussion of how to choose what to include and not to include in the system.

PHYSICS TOOL BOX 7.1 Constructing a qualitative work-energy bar chart



1. Choose and describe the initial and final states.

2. Choose a system.

3. Represent the energies in the initial state on the left side of the bar chart.

4. Represent the energies in the final state on the right side of the bar chart.

5. Determine the work done by external forces. (No external work is done in this process.)

TIP In Physics Tool Box 7.1, the system is isolated. No work is done on it. If we do not include Earth in the system, then Earth will do negative work on the cart. However, such a system will not have gravitational potential energy.

The generalized work-energy principle

We found experimentally that the energy of an isolated system is constant. We also defined work as a mechanism for energy transfer. Therefore, we can summarize what we have learned about work and energy with the **generalized work-energy principle**.

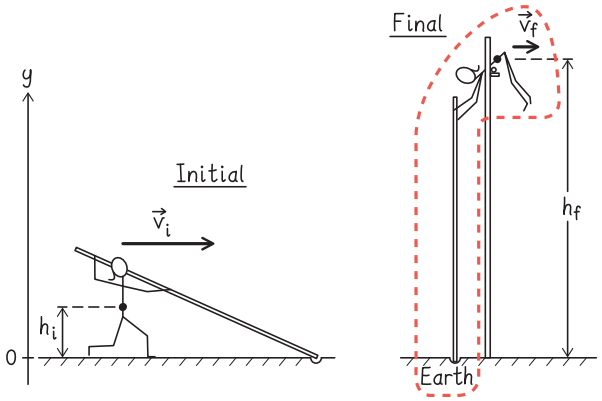
Generalized work-energy principle The sum of the initial energies of a system plus the work done on the system by external forces equals the sum of the final energies of the system:

$$E_i + W = E_f \tag{7.3}$$

or

$$(K_i + U_{gi} + U_{si}) + W = (K_f + U_{gf} + U_{sf} + \Delta U_{int}) \tag{7.3}$$

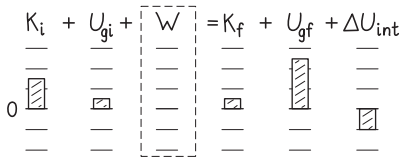
Note that we have moved $U_{int\,i}$ to the right hand side ($\Delta U_{int} = U_{int\,f} - U_{int\,i}$) since values of internal energy are rarely known, while internal energy changes are. We will also call Eq. (7.3) the *work-energy equation*.



The generalized work-energy principle allows us to define the total energy of a system as the sum of the different types of energy in the system. Total energy is measured in the same units as work and changes when work is done on the system. In Eq. (7.3), kinetic energy and gravitational and elastic potential energy are forms of **mechanical energy**. Mechanical energy is associated with motion and interactions of macroscopic objects—objects that we can see with our eyes. Internal energy is associated with motion and interactions of microscopic objects—objects that we cannot see with our eyes. Unlike such physical quantities as position or force, energy is not directly observed, and there are no instruments that measure energy. We can only infer the amount of any type of energy if we can express it through measurable quantities.

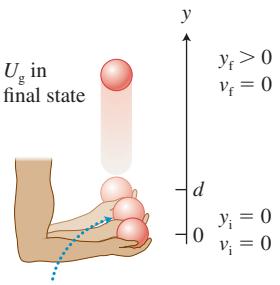
The work in Eq. (7.3) can be positive or negative. Unlike velocity and acceleration, for which plus and minus signs signify direction, in the case of work the sign signifies another operation—addition or subtraction.

CONCEPTUAL EXERCISE 7.2 Pole vaulting, qualitatively



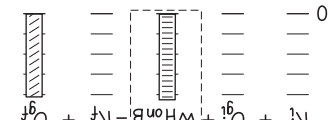
Qualitatively analyze a pole vault from an energy perspective by first drawing a sketch and then a work-energy bar chart.

Sketch and translate To analyze the process, we choose the final state to be when a pole vaulter is just clearing the bar. What should be the initial state? As we discussed at the beginning of the chapter, pole vaulters run very fast while holding an unbent pole, then insert the pole into the vaulting box. Next, using the bent pole, they lift themselves above the bar. When they have just cleared the bar, they are still holding the pole, but it is no longer bent. Thus it makes sense to choose the moment when the pole vaulter is running, just before she inserts the pole into the box, as the initial state. In both of these states the pole is not deformed, so we do not need to worry about changes in the pole's elastic energy or the pole doing work on the system. Therefore, it does not matter whether it is in the system or not. Let's choose the pole vaulter, Earth, and the pole as the system. The beauty of the energy approach is that we are only concerned with what is happening in the initial and final states, not with the processes in between. The sketch shows the pole-vaulting process with the initial and final states marked.



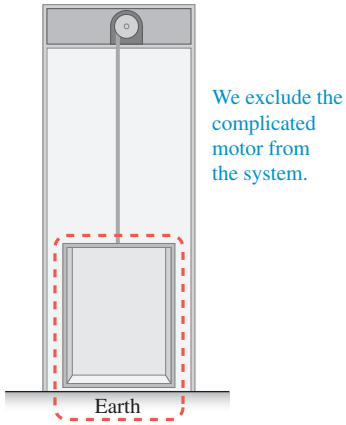
Simplify and diagram Assume that the pole vaulter can be modeled as a point-like object with her mass concentrated approximately in the middle of her body. Between the initial and final states there are no external forces exerted on the system; thus there is no work done. Using our understanding of energy, we can say that the gravitational potential energy U_{gi} of the system and the kinetic energy K_i of the vaulter in the initial state are converted to the final gravitational potential energy U_{gf} and a little bit of kinetic energy K_f (the vaulter needs to be moving horizontally a little in order not to fall straight down when no longer in contact with the pole) of the system in the final state. To draw the bars for gravitational potential energy, we assume that it is zero at ground level.

However, if we carefully watch videos of pole vaulters on the Internet, we see that right after inserting the pole into the box, they jump while bending the pole as they start their vertical ascent. They also crunch their muscles at the top of their flight to produce a specific body shape as they pass over the bar. During both of these actions, the vaulters convert some of their internal energy into the mechanical energy of the system. This means that the internal energy of the system is less in the final state than in the initial state. To represent this, we draw the bar for the internal energy *change* ΔU_{int} below the axis to indicate that the internal energy of the pole vaulter between the moment she inserts the pole in the vaulting box and when she clears the bar decreases. The pole vaulter does not cool down during the process, so where does this internal energy come from? It comes from the chemical energy stored in her body. From the bar chart, we reason that the greater the initial kinetic energy and the more internal energy the vaulter can "pump" into the vault, the greater the final gravitational potential energy, or the height of the vault. Note that we did not take into account the initial kinetic energy of the pole or the internal energy change due to its deformation (it could have gotten a little warmer).



Try it yourself You throw a ball straight upward as shown at right. The system is the ball and Earth (but not your hand). Ignore interactions with the air. Draw a work-energy bar chart starting when the ball is at rest in your hand and ending when the ball is at the very top of its flight.

Hand does work on ball only when it is in contact with the ball.



Answer

See the diagram. Note that there is no kinetic energy represented in the bar chart because the ball was not moving in either the initial state or the final state. It does not matter that it was moving in the time interval between those two states.

In Table 7.4 we chose different systems to analyze different parts of a process. In general, how do we know what to include and what not to include in a system to make the analysis of a process easier? Generally, it is preferable to have a larger system so that the changes occurring can be included as energy changes within the system rather than as the work done by external forces. However, often it is best to exclude something like a motor from a system because its energy changes are complex. For instance, if you are

FIGURE 7.2 Energy changes in the motor pulling up on the elevator cable are very complicated.

studying a moving elevator (**Figure 7.2**), you might choose to exclude from the system the motor that turns the cable while lifting the elevator. The motor's cable does positive work on the system by exerting a tension force on the elevator when the elevator is moving up and negative work when the elevator is moving down. You can take into account the effect of the motor by calculating the work done by the cable on the elevator.

REVIEW QUESTION 7.2 A system can possess energy but it cannot possess work. Why?

7.3 Quantifying gravitational potential and kinetic energies

In this section we will use what we know about work, forces, and kinematics to devise mathematical expressions for gravitational potential energy and kinetic energy.

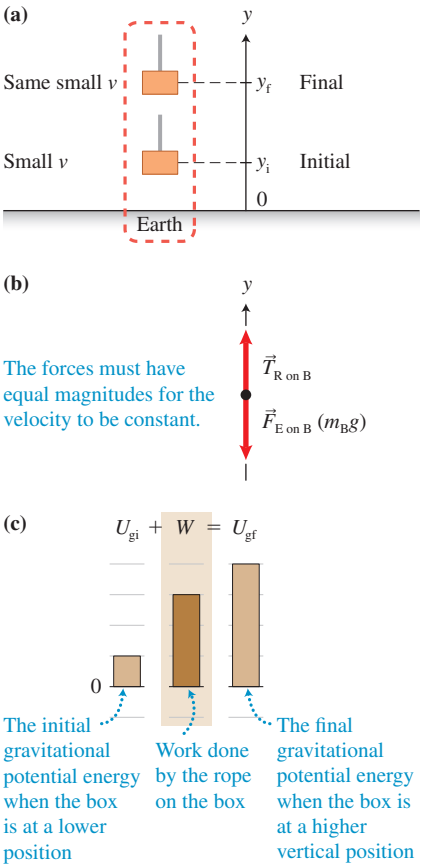
Gravitational potential energy

Imagine that a rope lifts a heavy box upward at a constant negligible velocity (**Figure 7.3a**). The rope is attached to a motor above, which is not shown in the figure. First, we choose only the box as the system and apply Newton's second law to find the magnitude of the force that the rope exerts on the box. Since the box moves up at constant velocity, the upward tension force $\vec{T}_{\text{R on B}}$ exerted by the rope on the box is equal in magnitude to the downward gravitational force $\vec{F}_{\text{E on B}}$ exerted by Earth on the box (see the force diagram in Figure 7.3b), $m_{\text{B}}g$, we find that the magnitude of the tension force for this process is $T_{\text{R on B}} = m_{\text{B}}g$.

To derive an expression for gravitational potential energy, we must change the boundaries of the system to include the box and Earth (if Earth is not included in the system, the system does not have gravitational potential energy). The origin of a vertical y-axis is the ground directly below the box with the positive direction upward. The initial state of the system is the box at position y_{i} moving upward at a negligible speed $v_{\text{i}} \approx 0$. The final state is the box at position y_{f} moving upward at the same negligible speed $v_{\text{f}} \approx 0$. According to work-energy Eq. (7.3),

$$E_{\text{i}} + W = E_{\text{f}}$$

The rope does work on the box, lifting the box from vertical position y_{i} to y_{f}:



$$W_{\text{R on B}} = T_{\text{R on B}} d \cos\theta = T_{\text{R on B}} (y_{\text{f}} - y_{\text{i}}) \cos 0^\circ = m_{\text{B}}g\,(y_{\text{f}} - y_{\text{i}})$$

where we substituted $T_{\text{R on B}} = m_{\text{B}}g$ and $\cos 0^\circ = 1$. The kinetic energy did not change. Substituting this expression for work into the work-energy equation, we get

$$U_{\text{gi}} + m_{\text{B}}g\,(y_{\text{f}} - y_{\text{i}}) = U_{\text{gf}}$$

Figure 7.3c represents this information with an energy bar chart. We now have an expression for the change in the gravitational potential energy of the system: $U_{\text{gf}} - U_{\text{gi}} = m_{\text{B}}gy_{\text{f}} - m_{\text{B}}gy_{\text{i}}$. This suggests the following definition for the gravitational potential energy of a system.

FIGURE 7.3 Lifting a box at a negligible constant speed.

Gravitational potential energy The gravitational potential energy of an object-Earth system is

$$U_{\text{g}} = mgy \tag{7.4}$$

where m is the mass of the object, $g = 9.8\ \text{N/kg}$, and y is the position of the object with respect to the **zero level of gravitational potential energy** (the origin of the coordinate system is our choice). The units of gravitational potential energy are $\text{kg(N/kg)m} = \text{N}\cdot\text{m} = \text{J}$ (joule), the same unit used to measure work and the same unit for every type of energy.

TIP Three things are important here:

1. The value of U_g depends on our choice of zero for the y-coordinate. According to Eq. (7.4), this is where U_g is zero. However, the *change* in U_g does not depend on the choice of the zero level.
2. The derivation of Eq. (7.4) assumed that g is constant. We will look at nonconstant g later in the chapter.
3. If Earth is not included in the system, the system does not have any U_g, but Earth can do work on the system.

Kinetic energy

Next, we analyze a simple thought experiment to determine an expression for the kinetic energy of a system that consists of a single object. Imagine that your hand exerts a force $\vec{F}_{\text{H on C}}$ on a cart of mass m while pushing it toward the right a displacement $\vec{d}$ on a horizontal frictionless surface (**Figure 7.4a**). A bar chart for this process is shown in Figure 7.4b. There is no change in gravitational potential energy. The kinetic energy changes from the initial state to the final state because of the work done by the external force exerted by your hand on the cart:

$$K_i + W_{\text{H on C}} = K_f$$

or

$$W_{\text{H on C}} = K_f - K_i$$

We know that the work in this case equals $F_{\text{H on C}}d \cos 0° = F_{\text{H on C}}d$. Thus,

$$F_{\text{H on C}}d = K_f - K_i$$

This does not look like a promising result—the kinetic energy change on the right equals quantities on the left side that do not depend on the mass or speed of the cart. However, we can use dynamics and kinematics to get a result that does depend on these properties of the cart. The horizontal component form of Newton's second law is

$$m_C a_C = F_{\text{H on C}}$$

We can rearrange a kinematics equation ($v_f^2 = v_i^2 + 2ad$) to get an expression for the displacement of the cart in terms of its initial and final speeds and its acceleration:

$$d = \frac{v_f^2 - v_i^2}{2a_C}$$

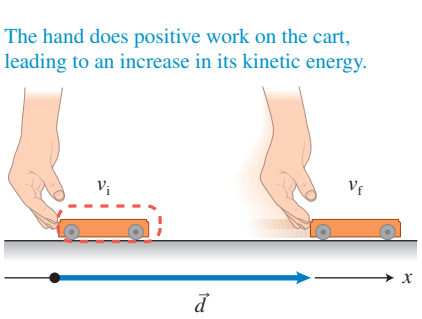
Now, we insert these expressions for force and displacement into the left side of the equation $F_{\text{H on C}}d = K_f - K_i$:

$$F_{\text{H on C}}d = (m_C a_C)\left(\frac{v_f^2 - v_i^2}{2a_C}\right) = m_C\left(\frac{v_f^2}{2} - \frac{v_i^2}{2}\right) = \tfrac{1}{2}m_C v_f^2 - \tfrac{1}{2}m_C v_i^2$$

We can now insert this result into the equation $F_{\text{H on C}}d = K_f - K_i$:

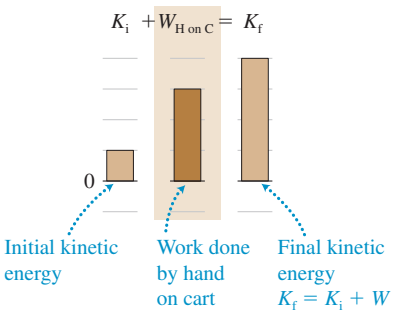
$$\tfrac{1}{2}m_C v_f^2 - \tfrac{1}{2}m_C v_i^2 = K_f - K_i$$

It appears that $\frac{1}{2}m_C v^2$ is an expression for the kinetic energy of the cart.



Kinetic energy The kinetic energy of an object is

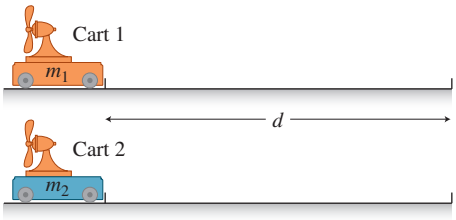
$$K = \tfrac{1}{2}mv^2 \qquad (7.5)$$



where m is the object's mass and v is its speed relative to the chosen coordinate system. Notice that kinetic energy is always positive.

FIGURE 7.4 The work done by the hand causes the cart's kinetic energy to increase.

(a)



(b)

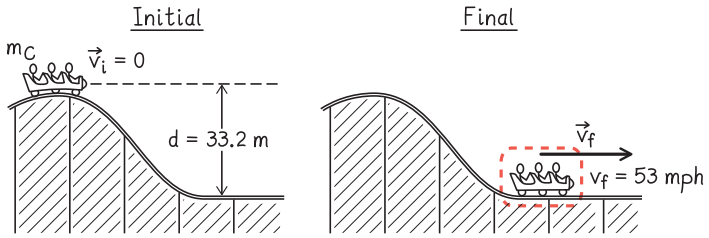
TIP Remember that speed is relative—it depends on the observer. A person on a Boeing 747 airplane would consider the kinetic energy of a 70-kg passenger next to her as zero, while a person on the ground would find the kinetic energy of the same person to be about 2.5 million joules.

To check whether the unit of kinetic energy is the joule (J), we insert the units into Eq. (7.5): $\frac{\text{kg}\cdot\text{m}^2}{\text{s}^2} = \left(\frac{\text{kg}\cdot\text{m}}{\text{s}^2}\right)\text{m} = \text{N}\cdot\text{m} = \text{J}$.

FIGURE 7.5 Two fan carts of different masses with identical fans.

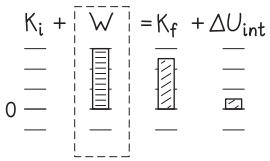
It is important to understand the differences between force, acceleration, work, impulse, momentum, and kinetic energy. To illustrate this, we will perform the following thought experiment. Imagine two carts on a smooth surface that have identical fans attached but different masses. The fans rotate and push away the air around the carts; according to Newton's third law, the air pushes on the carts in the opposite direction, making them accelerate. Both carts start from rest, and we let them move the *same distance* on the floor (see **Figure 7.5**). **Table 7.5** compares the above physical quantities for the two carts. Notice that some quantities are the same for both carts, some are larger for cart 1, and some are larger for cart 2. Your task is to think about the explanations for the statements in the table.

TABLE 7.5 Physical quantities describing the motion of two fan carts



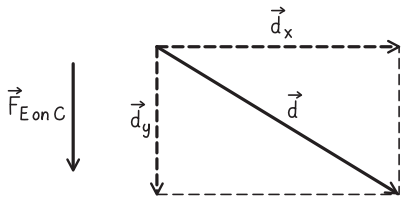
Quantity	Cart 1 (mass m_1)	Cart 2 (mass $m_2 = 2m_1$)
Force exerted by the air on the fan cart	$\vec{F}_{\text{A on 1}} = \vec{F}$	$\vec{F}_{\text{A on 2}} = \vec{F}_{\text{A on 1}} = \vec{F}$ Same as cart 1
Acceleration of the cart	$\vec{a}_1 = \frac{\vec{F}}{m_1}$	$\vec{a}_2 = \frac{\vec{F}}{m_2} = \frac{\vec{F}}{2m_1} = \frac{1}{2}\vec{a}_1$ Less than cart 1
Time interval to travel distance d	$\Delta t_1 = \sqrt{\frac{2d}{a_1}}$	$\Delta t_2 = \sqrt{\frac{2d}{a_2}} = \sqrt{\frac{4d}{a_1}} = \sqrt{2}\Delta t_1 > \Delta t_1$ Greater than cart 1
Work done by the fan on the cart	$W_{\text{A on 1}} = Fd\cos 0°$	$W_{\text{A on 2}} = Fd\cos 0° = W_{\text{A on 1}}$ Same as cart 1
Change of kinetic energy of the cart after moving distance d	$\Delta K_1 = \frac{m_1 v_{1\text{f}}^2}{2} = Fd$	$\Delta K_2 = \frac{m_2 v_{2\text{f}}^2}{2} = Fd = \Delta K_1$ Same as cart 1
Speed of the cart after moving distance d	$v_{1\text{f}} = \sqrt{\frac{2Fd}{m_1}}$	$v_{2\text{f}} = \frac{v_{1\text{f}}}{\sqrt{2}}$ Less than cart 1
Change of momentum of the cart after moving distance d	$m_1 v_{1\text{f}}$	$m_2 v_{2\text{f}} = 2m_1\frac{v_{1\text{f}}}{\sqrt{2}} = \sqrt{2}m_1 v_{1\text{f}}$ Greater than cart 1
Impulse exerted on the cart after moving distance d	$\vec{J} = \vec{F}\Delta t_1 = m_1\vec{v}_{1\text{f}}$	$\vec{J} = \vec{F}\Delta t_2 = m_2\vec{v}_{2\text{f}}$ Greater than cart 1

You might be surprised that the heavier, slower cart has a greater momentum gain than the lighter, faster cart but the same gain in kinetic energy. But if you think about the work done by the air on each cart (equal to force times distance because the cosine of the angle between the force and displacement is 1), it is the same; thus the change in kinetic energy must be the same.



EXAMPLE 7.3 Mystic Timbers roller coaster

The Mystic Timbers roller coaster in Ohio has a drop of 33.2 m. The maximum speed of the coaster at the bottom of this drop is 53 mph. Can we say that all work done by Earth on the roller coaster is converted to the coaster's kinetic energy during the ride?



Sketch and translate We first draw a sketch of the roller coaster and mark the givens, assuming that the coaster starts from rest at the top of the track. We choose the initial state to be just before the roller coaster starts to drop and the final state to be at the very bottom of the drop. Because the problem asks about the work done by Earth, Earth should not be in the system—we include only the coaster and the track in the system.

Simplify and diagram A work-energy bar chart representing the process is shown at right. Because Earth is not in the system, Earth does work on the coaster, but the system does not have gravitational potential energy in any state. In the initial state, the system has no kinetic energy. In the final state, it has kinetic energy and possibly a change in internal energy (the coaster wheels and the track could warm up), but we are not sure.

Because the force that Earth exerts on the coaster points down, it only does work on the coaster due to the coaster's *vertical* displacement. This is because the work done by Earth on the coaster during the horizontal displacement of the coaster is zero, and the total displacement of the coaster can be decomposed into vertical and horizontal displacement components, as shown below.

Represent mathematically We use the bar chart to write the work-energy equation:

$$0 + W = K_f + \Delta U_{int}$$

Because we do not know the mass of the coaster, we cannot calculate the work done by Earth on the coaster or the coaster's final kinetic energy. However, we can check whether all work goes into the kinetic energy increase. If it does, the final speed of the coaster calculated using this assumption should be equal to the reported final speed of the coaster.

$$W_{E\,on\,C} = F_{E\,on\,C} d \cos\theta = F_{E\,on\,C} d \cos 0^\circ = F_{E\,on\,C} d = m_C g d$$

$$\text{and } K_f = \tfrac{1}{2} m_C v_f^2$$

Inserting these into the work-energy equation with the assumption that $\Delta U_{int} = 0$ gives

$$0 + m_C g d = \tfrac{1}{2} m_C v_f^2 \implies v_f = \sqrt{2gd}$$

Solve and evaluate $v_f = \sqrt{2 \times (9.8\ \text{m/s}^2) \times (33.2\ \text{m})} = 25.5\ \text{m/s}$.

The reported final speed of the coaster is

$$53\ \text{mph} = \frac{(53\ \text{miles/h}) \times (1600\ \text{m/mile})}{3600\ \text{s/h}} = 23.6\ \text{m/s}$$

This reported final speed is about 7% $\left(\dfrac{25.5 - 23.6}{25.5} = 0.07\right)$ less than it would be if we assumed that all of the work done by the gravitational force went into the increase of the kinetic energy of the roller coaster. Thus some of this work went into an increase of the coaster and track's internal energy (and maybe some to the air around it).

Try it yourself Change the system in this example to include Earth. Does the result change? How does the work-energy bar chart change?

Answer The roller coaster speed calculated for the new system is the same. On the bar chart there is no work done, but the system instead has an initial gravitational potential energy bar of the same height as the previous work done bar. The kinetic energy and change in internal energy bars remain the same.

REVIEW QUESTION 7.3 When we use the work-energy equation, how do we incorporate the force that Earth exerts on an object?

7.4 Quantifying elastic potential energy

Our next goal is to construct a mathematical expression for the elastic potential energy stored by an elastic object when it has been stretched or compressed. We have a special problem in deriving this expression. Previously, we investigated work done by constant forces. However, when you stretch or compress an elastic spring-like object, you have to pull or push harder the more the object is stretched or compressed. The force is not constant. How does the force you exert to stretch a spring-like object change as the object stretches?

Hooke's law

To answer this question, we use two springs of the same length: a thinner and less stiff spring 1 and a thicker and stiffer spring 2 (**Figure 7.6a**). The springs are attached at the left end to a rigid object and placed on a smooth surface. We use a scale to pull on the right end of each spring, exerting a force whose magnitude F can be measured by the scale (Figure 7.6b). We record F and the distance x that each spring stretches from its unstretched position (see **Table 7.6**).

FIGURE 7.6 Measuring spring stretch x caused by a scale exerting force F on a spring.

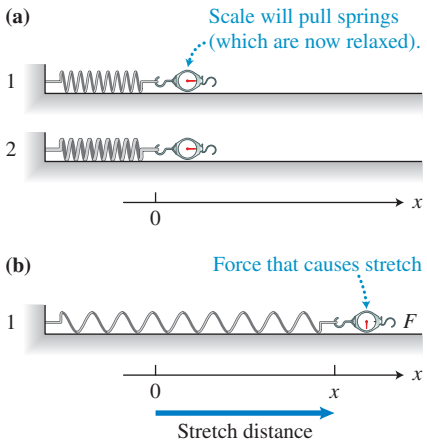


TABLE 7.6 Result of pulling on springs while exerting an increasing force

Force F exerted by the scale on the spring	Spring 1 stretch distance x	Spring 2 stretch distance x
0.00 N	0.000 m	0.000 m
1.00 N	0.050 m	0.030 m
2.00 N	0.100 m	0.060 m
3.00 N	0.150 m	0.090 m
4.00 N	0.200 m	0.120 m

FIGURE 7.7 A graph of the stretch of springs 1 and 2 when the same force is exerted on each spring.

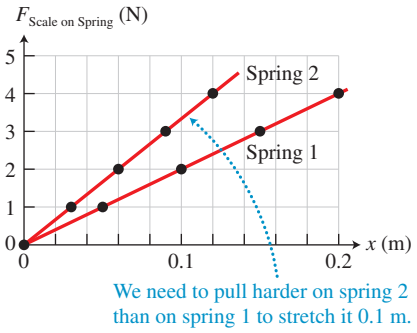

Figure 7.7 shows a graph of the Table 7.6 data. We use stretch distance x as an independent variable and the magnitude of the force $\vec{F}_{\text{Scale on Spring}}$ as a dependent variable. The magnitude of the force exerted by the scale on each spring is proportional to the distance that each spring stretches.

$$F_{\text{Scale on Spring}} = kx$$

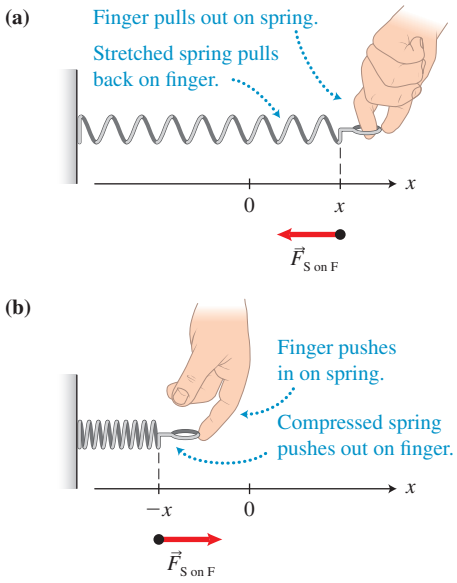
The coefficient of proportionality k (the slope of the F-versus-x graph) is called the **spring constant**. The slope for the stiffer spring 2 is larger $(33\ \text{N/m})$ than the slope for spring 1 $(20\ \text{N/m})$. In other words, to stretch spring 1 by 1.0 m we would have to exert only a 20-N force, but we would need a 33-N force for spring 2.

Often we are interested not in the force that something exerts on the spring, but in the force that the spring exerts on something else, $\vec{F}_{\text{Spring on Scale}}$. Using Newton's third law we have $\vec{F}_{\text{Spring on Scale}} = -\vec{F}_{\text{Scale on Spring}}$. The x-component of this force is

$$F_{\text{Spring on Scale } x} = -kx$$

Note that if an object stretches the spring to the right in the positive direction, the spring pulls back on the object in the opposite negative direction (**Figure 7.8a**; in this case, the object is your finger). If the object compresses the spring to the left in the negative

direction, the spring pushes back on the object in the opposite positive direction (Figure 7.8b). These observations are the basis for a relation first developed by Robert Hooke (1635–1703), called **Hooke's law**.



Elastic force (Hooke's law) If any object causes a spring to stretch or compress, the spring exerts an elastic force on that object. If the object stretches the spring along the x-direction, the x-component of the force the spring exerts on the object is

$$F_{\text{S on O}\,x} = -kx \tag{7.6}$$

The spring constant k is measured in newtons per meter and is a measure of the stiffness of the spring (or any elastic object); x is the distance that the object has been stretched/compressed (not the total length of the object). The elastic force exerted by the spring on the object points in a direction opposite to the direction it was stretched (or compressed)—hence the negative sign in front of kx. The object in turn exerts a force on the spring:

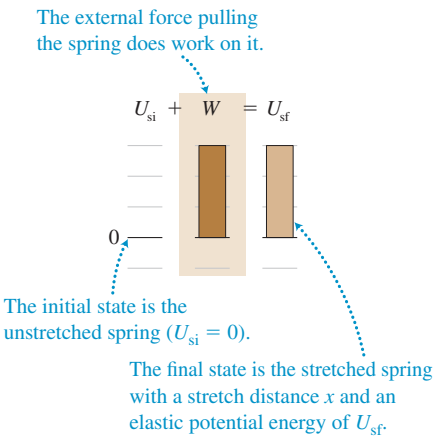
$$F_{\text{O on S}\,x} = +kx$$

FIGURE 7.8 Hooke's law.

Elastic potential energy

Our goal now is to develop an expression for the elastic potential energy of an elastic stretched or compressed object (such as a stretched spring). Consider the constant slopes of the lines in the graph shown in Figure 7.7. While stretching the spring with your hand from zero stretch ($x = 0$) to some arbitrary stretch distance x, the magnitude of the force your hand exerts on the spring changes in a linear fashion from zero when unstretched to kx when stretched.

To calculate the work done on the spring by such a variable force, we can replace this variable force with the average force $(F_{\text{H on S}})_{\text{average}}$:



$$(F_{\text{H on S}})_{\text{average}} = \frac{0 + kx}{2}$$

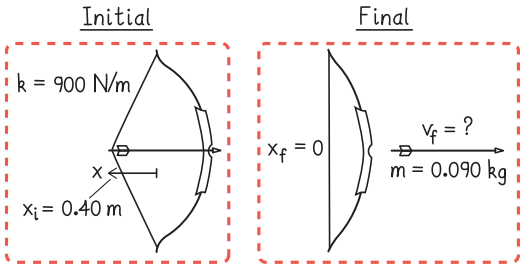
The force your hand exerts on the spring is in the same direction as the direction in which the spring stretches. Thus the work done by this force on the spring to stretch it a distance x is

$$W = (F_{\text{H on S}})_{\text{average}}\,x = (\tfrac{1}{2}kx)x = \tfrac{1}{2}kx^2$$

This work equals the change in the spring's elastic potential energy (see **Figure 7.9** for the bar chart). Assuming that the elastic potential energy of the unstretched spring is zero, the work we calculated above equals the final elastic potential energy of the stretched spring.

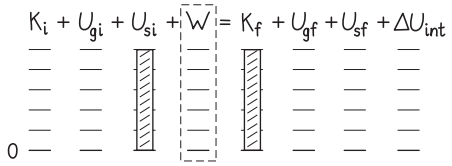
FIGURE 7.9 Bar chart showing that external work increases the elastic potential energy of the spring (the system).

Elastic potential energy The elastic potential energy of a spring-like object with a spring constant k that has been stretched or compressed a distance x from its undisturbed position is



$$U_s = \tfrac{1}{2}kx^2 \tag{7.7}$$

Just like any other type of energy, the unit of elastic potential energy is the joule (J).



EXAMPLE 7.4 **Shooting an arrow**

You load an arrow (mass = 0.090 kg) into a bow and pull the bowstring back 0.40 m. The bow has a spring constant $k = 900$ N/m. Determine the arrow's speed as it leaves the bow.

Sketch and translate We sketch the process, as shown below. The system is the bow and arrow. In the initial state, the bowstring is pulled back 0.40 m. In the final state, the string has just relaxed and the arrow has left the string.

Simplify and diagram Since the arrow moves horizontally, we do not need to keep track of gravitational potential energy. The initial elastic potential energy of the bow is converted into the final kinetic energy of the arrow. We represent the process with the bar chart.

Represent mathematically Use the bar chart to help apply the work-energy equation:

$$E_i + W = E_f$$
$$\Rightarrow K_i + U_{si} + 0 = K_f + U_{sf}$$
$$\Rightarrow 0 + \tfrac{1}{2}kx^2 = \tfrac{1}{2}mv^2 + 0$$

Multiply both sides of the above by 2, divide by m, and take the square root to get

$$v = \sqrt{\frac{k}{m}}x$$

Solve and evaluate

$$v = \sqrt{\frac{k}{m}}x = \sqrt{\frac{900\ \text{N/m}}{0.090\ \text{kg}}}(0.40\ \text{m}) = 40\ \text{m/s}$$

This is reasonable for the speed of an arrow fired from a bow. The units of $\sqrt{\frac{k}{m}}x$ are equivalent to $\frac{\text{m}}{\text{s}}$:

$$\sqrt{\frac{\text{N}}{\text{m}\cdot\text{kg}}}(\text{m}) = \sqrt{\frac{\text{kg}\cdot\text{m}}{\text{s}^2\cdot\text{m}\cdot\text{kg}}}(\text{m}) = \frac{\text{m}}{\text{s}}$$

Try it yourself If the same arrow were shot vertically, how high would it go?

Answer 82 m.

REVIEW QUESTION 7.4 If the magnitude of the force exerted by a spring on an object is kx, why is it that the work done to stretch the spring a distance x is not equal to $kx \cdot x = kx^2$?

7.5 Friction and energy conversion

In nearly every mechanical process, objects exert friction forces on each other. Sometimes the effect of friction is negligible (for example, in an air hockey game), but most often friction is important (for example, when a driver applies the brakes to avoid a collision). Our next goal is to investigate how we can incorporate friction into work and energy concepts. Let's analyze a car skidding to avoid an accident.

Can a friction force do work?

Imagine that you pull a rope attached to a box (the system) so that the box moves at constant velocity on a rough carpet (**Figure 7.10a**). A force diagram for the box is shown in Figure 7.10b.

The bar chart (Figure 7.10c) shows that the force exerted by the rope does positive work on the box system; the friction force does negative work. These horizontal forces have exactly the same magnitude (the box is moving at constant velocity). Thus,

the sum of the work done by those forces on the system is zero and the energy of the system should not change.

$$T_{\text{R on B}}d\cos 0^\circ + f_{\text{k C on B}}d\cos 180^\circ = T_{\text{R on B}}d + (-f_{\text{k C on B}}d) = 0$$

However, if you touch the bottom of the box at its final position, you find that it is warmer than before you started pulling and the box has scratches on its bottom. Again, the internal energy of the box increased. We get $0 = \Delta U_{\text{int}}$, where ΔU_{int} is greater than zero. The zero work done on the box does *not* equal the positive increase in internal energy. This is a contradiction of the work-energy principle. How can we resolve this?

The effect of friction as a change in internal energy

The key to resolving this problem is to change the system. The new system will include both surfaces that are in contact, for example, the box and the carpet. The friction force is then an internal force and therefore does no work on the system. But there is a change in the internal energy of the system caused by friction between the two surfaces.

When the rope is pulling the box across the rough carpet at constant velocity, we know that if the rope pulls horizontally on the box, the magnitude of the force that it exerts on the box $T_{\text{R on B}}$ must equal the magnitude of the friction force that the carpet exerts on the box $f_{\text{k C on B}}$. But now the box and carpet are both in the system—so the force exerted by the rope is the only external force. Thus the work done on the box-carpet system is

$$W = T_{\text{R on B}}d\cos 0^\circ$$

Substituting $T_{\text{R on B}} = f_{\text{k C on B}}$ and $\cos 0^\circ = 1.0$ into the above, we get

$$W = +f_{\text{k C on B}}d$$

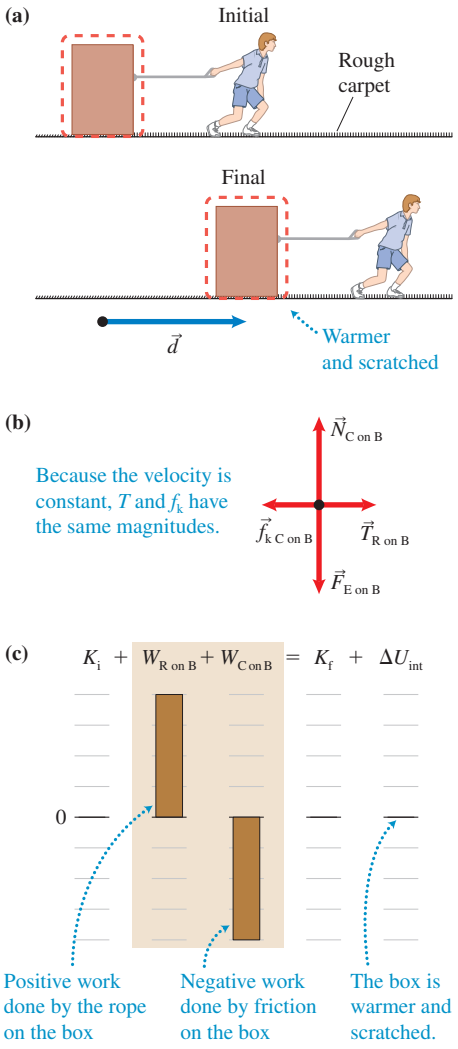
The only system energy change is its internal energy ΔU_{int}. The work-energy equation for pulling the box across the surface is

$$W = \Delta U_{\text{int}}$$

After inserting the expression for the work done on the box and rearranging, we get

$$\Delta U_{\text{int}} = +f_{\text{k}}d$$

We have constructed an expression for the change in internal energy of a system caused by the friction force that the two contacting surfaces in the system exert on each other when one object moves a distance d across the other.



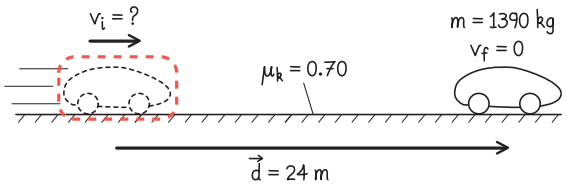
Increase in the system's internal energy due to friction

$$\Delta U_{\text{int}} = +f_{\text{k}}d \qquad (7.8)$$

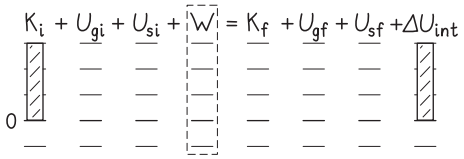
where f_{k} is the magnitude of the average friction force exerted by the surface on the object moving relative to the surface, and d is the distance that the object moves across that surface. The increase in internal energy is shared between the moving object and the surface.

Including friction in the work-energy equation as an increase in the system's internal energy produces the same result as calculating the work done by friction force. In this new approach, there is an increase in internal energy $\Delta U_{\text{int}} = +f_{\text{k}}d$ in a system that includes the two surfaces rubbing against each other (this expression goes on the right side of the work-energy equation). When we include the two surfaces in the system, we can see why the moving box gets warmer and why there might be structural changes.

FIGURE 7.10 Pulling a box across a rough carpet.



If we include only the box in the system, tracking the interactions between the system and the environment becomes very complicated because mass and thermal energy are transferred between the system and the environment. Therefore, in this book we prefer to include both surfaces in the system and consider the increase in internal energy caused by friction.



EXAMPLE 7.5 Skidding to a stop

You are driving your car when another car crosses the road at an intersection in front of you. To avoid a collision, you apply the brakes, leaving 24-m skid marks on the road while stopping. A police officer observes the near collision and gives you a speeding ticket, claiming that you were exceeding the 35 mi/h speed limit. She estimates your car's mass as 1390 kg and the coefficient of kinetic friction μ_k between your tires and this particular road as about 0.70. Do you deserve the speeding ticket?

Sketch and translate We sketch the process. We choose your car and the road surface as the system. We need to decide if your car was traveling faster than 35 mi/h at the instant you applied the brakes.

Simplify and diagram Assume that the process occurs on a horizontal level road and neglect interactions with the air. The initial state is just before the brakes are applied. The final state is just after your car has come to rest. We draw the energy bar chart to represent the process. In the initial state, the system has kinetic energy. In the final state, the system has no kinetic energy and has increased internal energy due to friction.

Represent mathematically Convert the bar chart into an equation:

$$K_i + 0 = U_{int\,f}$$
$$\Rightarrow \tfrac{1}{2}m_C v_i^2 = f_{k\,R\,on\,C}d = (\mu_k N_{R\,on\,C})d$$

The magnitude of the upward normal force $N_{R\,on\,C}$ that the road exerts on the car equals the magnitude of the downward gravitational force $F_{E\,on\,C} = m_C g$ that Earth exerts on the car: $N_{R\,on\,C} = m_C g$. Thus the above becomes

$$\tfrac{1}{2}m_C v_i^2 = \mu_k m_C g d$$

Solve and evaluate Rearranging the above and canceling the car mass, we get

$$v_i = \sqrt{2\mu_k g d} = \sqrt{2(0.70)(9.8\ \text{N/kg})(24\ \text{m})}$$
$$= (18.1\ \text{m/s})\left(\frac{1\ \text{mi/h}}{0.447\ \text{m/s}}\right) = 41\ \text{mi/h}$$

It looks like you deserve the ticket. We ignored the resistive drag force that air exerts on the car, which could be significant for a car traveling at 41 mi/h. Thus, air resistance helps the car's speed decrease, which means you actually were traveling faster than 41 mi/h.

Try it yourself Imagine the same situation as above, only you are driving a 2000-kg minivan. Will the answer for the initial speed increase or decrease?

Answer The speed does not change.

REVIEW QUESTION 7.5 Why, when friction cannot be neglected, is it useful to include both surfaces in the system when analyzing processes using the energy approach?

7.6 Skills for analyzing processes using the work-energy principle

The general strategy for solving problems with the work-energy principle is described on the left side of the table in Example 7.6 and illustrated on the right side for a specific process.

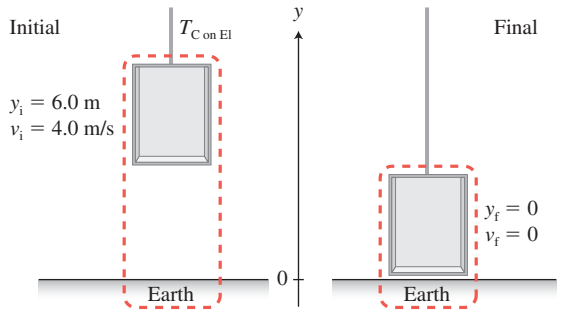
PROBLEM-SOLVING STRATEGY 7.1 Applying the work-energy principle

Sketch and translate

- Sketch the initial and final states of the process, labeling known and unknown information.
- Include the object of reference and the coordinate system.
- Choose the system of interest. Sometimes you might need to go back and redefine your system after you draw a bar chart if you find that the chosen system is not convenient.

Simplify and diagram

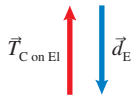
- What simplifications can you make to the objects, interactions, and processes?
- Decide which energy types are changing.
- Are external objects doing work?
- Use the initial-final sketch to help draw a work-energy bar chart. Include work bars (if needed) and initial and final energy bars for the types of energy that are changing. Specify the zero level of gravitational potential energy.



Represent mathematically

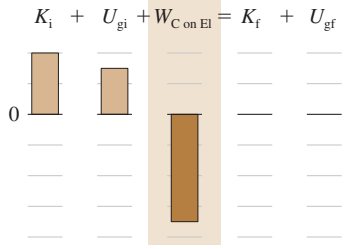
- Convert the bar chart into a mathematical description of the process. Each bar in the chart will appear as a single term in the equation.

EXAMPLE 7.6 An elevator slows to a stop



A 1000-kg elevator is moving downward. While moving down at 4.0 m/s, its speed decreases steadily until it stops in 6.0 m. Determine the magnitude of the tension force that the cable exerts on the elevator ($T_{\text{C on El}}$) while it is stopping.

- The elevator and Earth are in the system. We exclude the cable—its effect will be included as the work done by the cable on the elevator.



- The observer is on the ground; the coordinate system has a vertical axis pointing up with the zero at the bottom of the shaft.

- We assume that the cable exerts a constant force on the elevator and that the elevator can be considered a point-like object since all of its points move the same way (no deformation).
- We will keep track of kinetic energy (since the elevator's speed changes) and gravitational potential energy (since the elevator's vertical position changes).
- The tension force exerted by the cable on the elevator does negative work (the tension force points up, and the displacement of the elevator points down).

- The zero gravitational potential energy is at the lowest position of the elevator. In its initial state the system has kinetic energy and gravitational potential energy. In its final state the system has no energy.

$$E_i + W = E_f$$

$$\tfrac{1}{2}mv_i^2 + mgy_i + T_{\text{C on El}}(y_i - 0)\cos 180^\circ = 0$$

$$\tfrac{1}{2}mv_i^2 + mgy_i - T_{\text{C on El}}\,y_i = 0$$

(CONTINUED)

Solve and evaluate

- Solve for the unknown and evaluate the result.
- Does it have the correct units? Is its magnitude reasonable? Do the limiting cases make sense?

$$T_{\text{C on El}} = mg + \frac{mv_i^2}{2y_i}$$

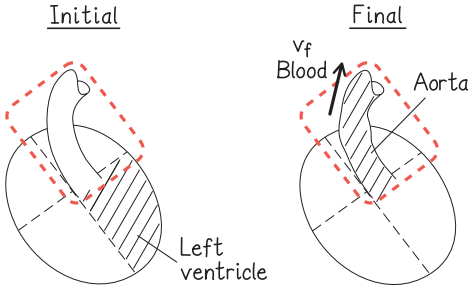
$$= (1000\text{ kg})(9.8\text{ N/kg}) + \frac{(1000\text{ kg})(4.0\text{ m/s})^2}{2(6.0\text{ m})}$$

$$= 11{,}000\text{ N}$$

- The result has the correct units. The force that the cable exerts is more than the 9800-N force that Earth exerts. This is reasonable since the elevator slows down while moving down; thus the sum of the forces exerted on it should point up.
- Limiting case: If the elevator slowed down over a much longer distance (y_f = very large number instead of 6.0 m), then the force would be closer to 9800 N.

Try it yourself Solve the same problem using Newton's second law and kinematics.

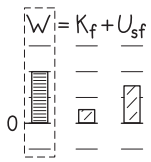
Answer 11,000 N.



The "Try it yourself" question above demonstrates that we can obtain the same result for Example 7.6 using Newton's second law and kinematics. However, the energy approach is often easier and quicker.

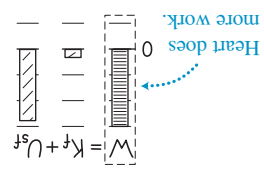
We have used the work-energy approach to examine several real-world phenomena. Let's use it to examine how the body pumps blood.

BIO CONCEPTUAL EXERCISE 7.7 Stretching the aorta



Every time your heart beats, the left ventricle pumps about 80 cm^3 of blood into the aorta, the largest artery in the human body. This pumping action occurs during a very short time interval, about 0.13 s. The elastic aorta walls stretch to accommodate the extra volume of blood. During the next 0.4 s or so, the walls of the aorta contract, applying pressure on the blood and moving it out of the aorta into the rest of the circulatory system. Represent this process with a qualitative work-energy bar chart.

Sketch and translate We sketch the process, as shown below. Choose the system to be the aorta and the 80 cm^3 of blood that is being pumped. The left ventricle is not in the system. Choose the initial state to be just before the left ventricle contracts. Choose the final state to be when the blood is in the stretched aorta before moving out into the rest of the circulatory system.



Simplify and diagram We keep track of the kinetic energy (the blood speed changes) and the elastic potential energy (the aorta wall stretches). We ignore the slight increase in the vertical elevation of the blood. The left ventricle is not in the system and does positive work pushing the blood upward in the direction of the blood's displacement. The work-energy bar chart below left represents this process for an aorta with flexible walls.

Flexible-walled aorta

Try it yourself Modify the work-energy bar chart for a person with hardened and thickened artery walls.

Answer If the person has stiff, thick arteries (a condition called atherosclerosis), more energy than normal is required to stretch the aorta walls. This process is represented by the bar chart to the right. In this case, the blood pressure is higher than it would be for a healthy cardiovascular system because the heart has to do more work to stretch the walls while pushing blood into the aorta.

In Conceptual Exercise 7.2 we discussed the physics of pole vaulting qualitatively; here we will solve a quantitative problem to figure out the contributions of different types of energy to the height of the jump. Make sure you review and continually consult Exercise 7.2, as both the sketch and the energy bar charts in that exercise are the same as in this problem.

EXAMPLE 7.8 Pole vaulting, quantitatively

65-kg, 1.74-m-tall Yelena Isinbayeva from Russia holds the women's pole-vaulting record of 5.06 m. Estimate the amount of internal energy that she converts into mechanical energy during the vault if before take-off she is running at a speed of 8.2 m/s, assuming that the change in the internal energy of the pole is negligible.

Sketch and translate See the sketch of the situation in Exercise 7.2. We choose the initial state as Yelena is running just before she inserts the pole into the vaulting box and the final state when she just clears the bar. The givens are $m = 65$ kg, $H_Y = 1.74$ m, $h_f = 5.06$ m, and $v_i = 8.2$ m/s. Yelena, Earth, and the pole are the system.

Simplify and diagram Again, we assume that Yelena can be modeled as a point-like object with her mass concentrated approximately in the middle of her body, which is moving at 8.2 m/s about $h_i = \frac{1}{2}H_Y \approx 0.9$ m above the ground. We also assume that she needs to be moving at a small but nonzero horizontal speed when she clears the bar, about 0.1 m/s ($v_f = 0.1$ m/s). In the final state, there should be some internal energy decrease because she converts this energy into mechanical energy when jumping as she starts her vertical ascent and at the top of the flight when she is crunching her muscles to give a specific body shape as she passes over the bar. We also assume that no other external forces are doing work on the system.

Represent mathematically We use the bar chart (see Exercise 7.2) to write the work-energy equation:

$$K_i + U_{gi} = K_f + U_{gf} + \Delta U_{int}$$

$$\Rightarrow \Delta U_{int} = K_i + U_{gi} - K_f - U_{gf} = (K_i - K_f) + (U_{gi} - U_{gf})$$

$$= \frac{m}{2}(v_i^2 - v_f^2) - mg(h_f - h_i)$$

Solve and evaluate We can now substitute the givens into the final equation:

$$\Delta U_{int} = \frac{(65.0\text{ kg})}{2}\left[(8.2\text{ m/s})^2 - (0.1\text{ m/s})^2\right] - (65.0\text{ kg}) \times (9.8\text{ m/s}^2)(5.06\text{ m} - 0.90\text{ m})$$

$$= 2184.98\text{ kg}\cdot\text{m}^2/\text{s}^2 - 2649.92\text{ kg}\cdot\text{m}^2/\text{s}^2$$

$$= -464.95\text{ J} \approx -465\text{ J}$$

The negative sign shows that the internal energy *decreases*—in agreement with the bar chart. We could now adjust the length of the bars: The bar for ΔU_{int} should be about 20% of the height of the bar for K_i. The internal energy decrease is significant but reasonable—it is still a small part of the kinetic energy of the pole vaulter. This is the energy that Yelena converted to the mechanical energy to reach the desired height. However, she probably converted some more of her internal energy into other forms of energy because we ignored the increase in the internal energy of the pole as well as the air.

Try it yourself The men's record for pole vaulting is 6.16 m. Estimate how much internal energy the vaulter converts to mechanical energy assuming his mass is 69 kg, his height is 1.77 m, and he runs 100 m in 11.4 s (8.77 m/s). Specify all assumptions you made.

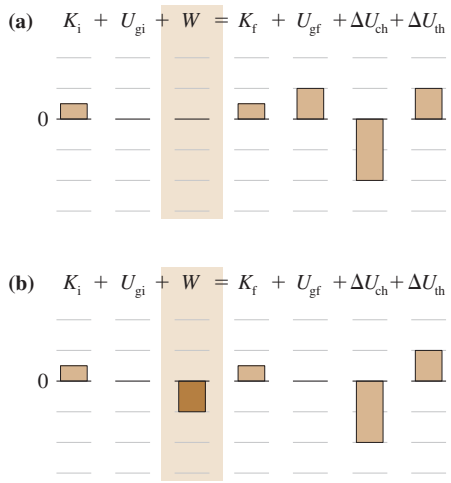
Answer About 930 J, assuming that all the vaulter's mass is concentrated at a point at the middle of the vaulter's height, and that the vaulter is not moving at the top of the flight.

Pole vaulting may not be part of your daily life, but there are plenty of everyday processes that we can analyze using a work-energy approach, for example, walking up the stairs. Let's choose the system to be you and Earth. The initial state is you on the first floor and the final state is you on the 10th floor. The gravitational potential energy of the system definitely increases. In addition, on the 10th floor you are sweating and the soles of your shoes and the surface of the stairs warm up a little due to the repeated deformation of the materials; thus the thermal energy (part of the internal energy) also increases. We have two increases; where does the energy for these increases come from? You might think that the stairs do work on you. However, it is not clear what the displacement is when you are in contact with each stair—different parts of your body move differently, so it is not clear what work the staircase does on you. Therefore, it is best to redefine the system to include the entire staircase.

The increases in gravitational potential and thermal energy of the you-Earth-staircase system came from the chemical energy of your muscles. The bar chart in

Figure 7.11a shows the average energy conversion across several stairs. We show the bar for the initial U_{gi} and the taller bar for the final U_{gf}, and we split the bar for internal energy change ΔU_{int} into two bars: chemical energy ΔU_{ch} and thermal energy ΔU_{th}. The thermal energy increases, but the chemical energy decreases. This is why you need to eat lunch to get back the expended energy! Note that if we did not include Earth in the system, the system would not have any gravitational potential energy, but Earth would do negative work. Therefore, some energy will need to increase to compensate for this negative work (see Figure 7.11b). In this situation, we see that including or excluding Earth from the system does not make any difference to the analysis, but including the staircase in the system simplifies the analysis.

FIGURE 7.11 Work-energy bar charts describing the process of walking up the stairs for different systems. (a) You, Earth and the staircase are in the system. (b) Earth is not in the system.



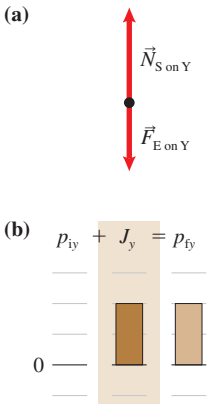


FIGURE 7.12 Force diagram and impulse-momentum bar chart for you pushing upward off a stair.

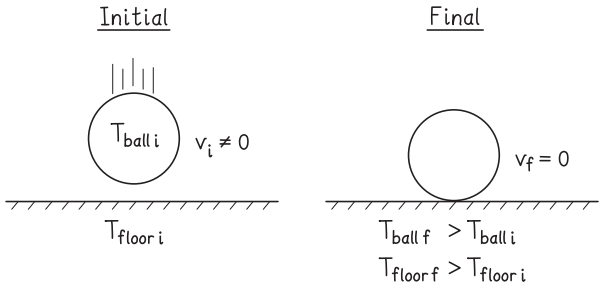
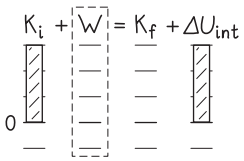


The work-energy approach describes the process, but does not explain it. During every step, you start at rest and then accelerate upward. If you are the system, then what are the objects responsible for your acceleration? You interact with Earth and the stair. The force exerted by the stair on you ($\vec{N}_{S\text{ on }Y}$) should be larger than the force exerted by Earth ($\vec{F}_{E\text{ on }Y}$) for you to accelerate upward (see the force diagram in Figure 7.12a).

Although the sum of the forces exerted by the stair and Earth on you does zero work (as there is no displacement of your feet while they are in contact with the floor), the sum of these two forces exerts a nonzero impulse on you due to the nonzero time interval of contact. Figure 7.12b shows the impulse-momentum bar chart for the process of each step. The initial state is right before you start your step, and the final state is when you are moving upward, but before you reach the next stair.



CONCEPTUAL EXERCISE 7.9 Dropping a steel ball

You drop a steel ball on the floor and take a picture of the floor with a thermal camera. The camera shows an increase in the temperature of the floor of about 4 °F; the ball gets a little hotter, too. Choose an appropriate system to analyze the energy conversions for the process that starts when the ball is about to hit the floor and ends when the ball is at rest on the floor.

Sketch and translate The initial and final states are provided in the givens. We show on the sketch a ball that is moving downward at speed v_i and then at rest (speed $v_f = 0$) on the floor. We also show the increased temperatures of the floor and the ball $\Delta T_{floor} > 0$; $\Delta T_{ball} > 0$. Because the floor did not move during the collision, it could not do any work on the ball. Therefore, we will include it in the system. Earth is irrelevant here because the distance between the ball and the floor does not change between the initial and final states.

Simplify and diagram The bar chart for the process is shown below. The left side shows the initial kinetic energy; the right side shows the change in internal energy. We assume that all this change is due to the temperature change of the ball and the floor.

Try it yourself Imagine that the ball lands on a trampoline instead of the floor. Analyze the process using the ball and Earth as the system. The initial state is when the ball touches the trampoline, and the final state is when the trampoline is stretched downward and the ball stops momentarily.

Answer After the ball first touches the trampoline, the trampoline stretches downward and exerts an increasing upward force on the ball in the direction opposite to the ball's downward motion. The trampoline therefore does negative work on the ball. This negative work decreases the kinetic energy of the ball. There is also a small decrease in the gravitational potential energy as the ball moves down with the trampoline.

REVIEW QUESTION 7.6 What would change in the solution to the problem in Example 7.8 if we did not include Earth in the system? Would the answer be different? Explain.

7.7 Collisions

A collision is a process that occurs when two (or more) objects are in direct contact with each other for a short time interval, such as when a baseball is hit by a bat (Figure 7.13). The ball compresses during the first half of the collision, then decompresses during the second half of the collision. We have already used impulse and momentum principles to analyze collisions (in Chapter 6). We learned that the forces that the two colliding objects exert on each other during the collision are complicated, nonconstant, and exerted for a very brief time interval—roughly 1 ms in the case of the baseball-bat collision. Can we learn anything new by analyzing collisions using the work-energy principle?

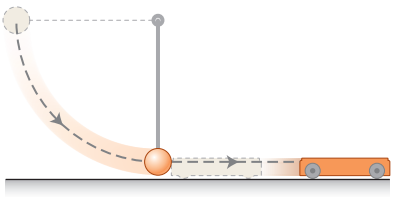


FIGURE 7.13 A baseball is compressed while being hit by a bat.

Analyzing collisions using momentum and energy principles

Observational Experiment Table 7.7, on the next page, shows three different observational experiments involving collisions. In each case a 1.0-kg object attached to the end of a string (the bob of a pendulum) swings down and hits a 4.0-kg wheeled cart at the lowest point of its swing (Figure 7.14). In each experiment, the pendulum bob and cart start at the same initial positions, but the compositions of the pendulum bob and cart are varied. After each collision, the cart moves at a nearly constant speed because of the smoothness of the surface on which it rolls.

FIGURE 7.14 A pendulum bob hits a cart, causing it to move forward.

OBSERVATIONAL EXPERIMENT TABLE 7.7 Analyzing momentum and energy during collisions

VIDEO OET 7.7

Observational experiment	Analysis
Experiment 1. A 1.0-kg metal bob swings and hits a 4.0-kg metal cart. Their velocity components just before and just after the collision are shown below: $m_1 = 1.0\ \text{kg}; v_{1ix} = 10\ \text{m/s}$ $v_{1fx} = -6.0\ \text{m/s}$ $m_2 = 4.0\ \text{kg}; v_{2ix} = 0\ \text{m/s}$ $v_{2fx} = 4.0\ \text{m/s}$	**Momentum:** Before collision: $(1.0\ \text{kg})(+10\ \text{m/s}) + (4.0\ \text{kg})\ 0 = +10\ \text{kg}\cdot\text{m/s}$ After collision: $(1.0\ \text{kg})(-6.0\ \text{m/s}) + (4.0\ \text{kg})(+4.0\ \text{m/s}) = +10\ \text{kg}\cdot\text{m/s}$ **Kinetic energy:** Before collision: $(1/2)(1.0\ \text{kg})(+10\ \text{m/s})^2 + (1/2)(4.0\ \text{kg})\ 0^2 = 50\ \text{J}$ After collision: $(1/2)(1.0\ \text{kg})(-6.0\ \text{m/s})^2 + (1/2)(4.0\ \text{kg})(+4.0\ \text{m/s})^2 = 50\ \text{J}$
Experiment 2. A 1.0-kg sand-filled balloon swings and hits a 4.0-kg flimsy cardboard cart. After the collision, the damaged cart moves across the table at constant speed. The side of the balloon that hit the cart is flattened in the collision. Their velocity components just before and just after the collision are shown below: $m_1 = 1.0\ \text{kg}; v_{1ix} = 10\ \text{m/s}$ $v_{1fx} = -4.2\ \text{m/s}$ $m_2 = 4.0\ \text{kg}; v_{2ix} = 0\ \text{m/s}$ $v_{2fx} = 3.55\ \text{m/s}$	**Momentum:** Before collision: $(1.0\ \text{kg})(+10\ \text{m/s}) + (4.0\ \text{kg})\ 0 = +10\ \text{kg}\cdot\text{m/s}$ After collision: $(1.0\ \text{kg})(-4.2\ \text{m/s}) + (4.0\ \text{kg})(+3.55\ \text{m/s}) = +10\ \text{kg}\cdot\text{m/s}$ **Kinetic energy:** Before collision: $(1/2)(1.0\ \text{kg})(+10\ \text{m/s})^2 + (1/2)(4.0\ \text{kg})\ 0^2 = 50\ \text{J}$ After collision: $(1/2)(1.0\ \text{kg})(-4.2\ \text{m/s})^2 + (1/2)(4.0\ \text{kg})(+3.55\ \text{m/s})^2 = 34\ \text{J}$
Experiment 3. A 1.0-kg sand-filled balloon covered with Velcro swings down and sticks to a 4.0-kg Velcro-covered cardboard cart. The string holding the balloon is cut by a razor blade immediately after the balloon contacts the cart. The damaged cart and flattened balloon move off together across the table. Their velocity components just before and just after the collision are shown below: $m_1 = 1.0\ \text{kg}; v_{1ix} = 10\ \text{m/s}$ $v_{1fx} = 2.0\ \text{m/s}$ $m_2 = 4.0\ \text{kg}; v_{2ix} = 0\ \text{m/s}$ $v_{2fx} = 2.0\ \text{m/s}$	**Momentum:** Before collision: $(1.0\ \text{kg})(+10\ \text{m/s}) + (4.0\ \text{kg})\ 0 = +10\ \text{kg}\cdot\text{m/s}$ After collision: $(1.0\ \text{kg})(+2.0\ \text{m/s}) + (4.0\ \text{kg})(+2.0\ \text{m/s}) = +10\ \text{kg}\cdot\text{m/s}$ **Kinetic energy:** Before collision: $(1/2)(1.0\ \text{kg})(+10\ \text{m/s})^2 + (1/2)(4.0\ \text{kg})\ 0^2 = 50\ \text{J}$ After collision: $(1/2)(1.0\ \text{kg})(+2.0\ \text{m/s})^2 + (1/2)(4.0\ \text{kg})(+2.0\ \text{m/s})^2 = 10\ \text{J}$

Patterns

Two important patterns emerge from the data collected from these different collisions.

- The momentum of the system is constant in all three experiments.
- The kinetic energy of the system is constant when no damage is done to the objects during the collision (Experiment 1 but not in Experiments 2 and 3).

We can understand the first pattern in Table 7.7 using our knowledge of impulse-momentum. The x-component of the net force exerted on the system in all three cases was zero; hence the x-component of momentum should be constant.

What about the second pattern? In Experiment 1, the objects in the system were very rigid, but in Experiments 2 and 3, they were more fragile and as a result were deformed during the collision. Using the data, we can determine the amount of kinetic energy that was converted to internal energy. But it is impossible to predict this amount ahead of time. Unfortunately, this means that in collisions where any deformation of the objects occurs, we cannot make predictions about the amount of kinetic energy converted to internal energy. However, we now know that even in collisions where the objects become damaged, the momentum of the system still remains constant. So even though the work-energy equation is less useful in these types of collisions, the impulse-momentum equation is still very useful.

Types of collisions

The experiments in Table 7.7 are examples of the three general collision categories: elastic collisions (Experiment 1), inelastic collisions (Experiment 2), and totally inelastic collisions (Experiment 3). **Table 7.8** summarizes these three types of collisions.

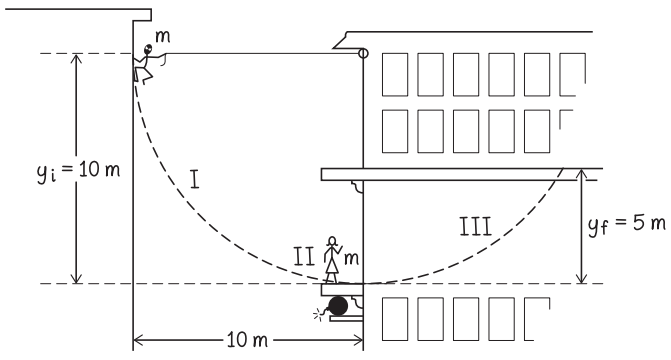

TABLE 7.8 Types of collisions

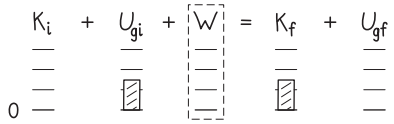
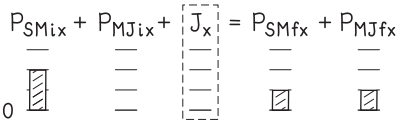
Elastic collisions	Inelastic collisions	Totally inelastic collisions
Both the momentum and kinetic energy of the system are constant. The internal energy of the system does not change. The colliding objects never stick together. Examples: There are no perfectly elastic collisions in nature, although collisions between very rigid objects (such as billiard balls) come close. Collisions between atoms or subatomic particles are almost exactly elastic.	The momentum of the system is constant but the kinetic energy is not. The colliding objects do not stick together. Internal energy increases during the collisions. Examples: A volleyball bouncing off your arms, or you jumping on a trampoline.	These are inelastic collisions in which the colliding objects stick together. Typically, a large fraction of the kinetic energy of the system is converted into internal energy in this type of collision. Examples: You catching a football, or a car collision where the cars stick together.

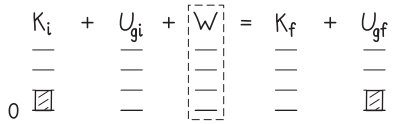


EXAMPLE 7.10 **Spiderman saves Mary Jane**

Spiderman is climbing up a building on one side of a 10-m-wide street when he spots Mary Jane 10 m below, standing on a platform on the other side of the street. The platform is about to explode. Spiderman swings down using his web and grabs Mary Jane, hoping to swing up with her to an open terrace, 5 m above the platform on the same building—where they both would be safe. Will they make it?



Sketch and translate Let's break the process into three parts: (I) Spiderman's swing from the first building down to Mary Jane (before they join together); (II) their brief impact, an inelastic collision (because they are traveling together after the impact); and (III) their swing together until they stop on the terrace. The givens are in the sketch below. We assume that the mass of Spiderman is the same as that of Mary Jane.



Simplify and diagram Consider Spiderman and Mary Jane to be point-like objects. For Part I, choose Spiderman, the web, and Earth as the system. During Spiderman's downward swing, the gravitational potential energy of the system is converted to his kinetic energy just before colliding with Mary Jane (see the work-energy bar chart, top right). We can use this to determine his speed just before impact. This way, we do not need to worry about the impulse exerted by the gravitational force on Spiderman to find his momentum at the bottom of the swing. The direction of the force exerted by Earth on Spiderman continually changes relative to the direction of his motion as he swings down, making calculations of impulse very difficult.

For Part II, the inelastic collision of Spiderman with Mary Jane, there will probably be an increase in internal energy. We can't use an energy analysis to decide how much—we don't have a way to independently determine internal energy change. Thus, we use only momentum conservation and impulse-momentum bar charts to determine Mary Jane and Spiderman's speed immediately after the collision (see the impulse-momentum bar chart below—the system is Spiderman and Mary Jane, who we have assumed have equal masses).

For Part III, knowing their speed after the collision, we can now use energy conservation to determine the maximum height they reach after the collision (see the work-energy bar chart below). Again, momentum conservation is very difficult because it involves the impulse caused by the gravitational force, which continually changes direction relative to the changing direction of motion as they swing upward.

Represent mathematically Use the energy bar charts from Part I to find that

$$mgy_i = \tfrac{1}{2}mv_{SM}^2$$

where $y_i = 10$ m is Spiderman's original height, and v_{SM} is his unknown speed just before grabbing Mary Jane. Dividing both sides of the equation by Spiderman's (nonzero) mass and rearranging, we get

$$v_{SM} = \sqrt{2gy_i}$$

We now use the outcome of the Part II momentum conservation collision process to determine their joint speed $v_{SM\text{-}MJ}$ immediately after the collision:

$$mv_{SM} = (m + m)v_{SM-MJ} \quad \text{or} \quad v_{SM-MJ} = \tfrac{1}{2}v_{SM}$$

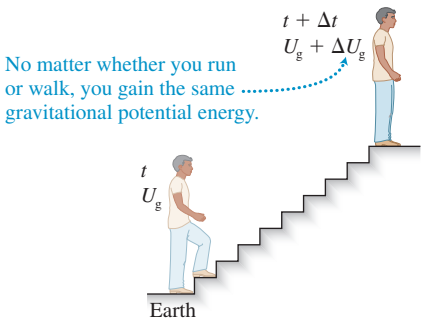
For Part III, the height to which they rise after the collision is determined using energy conservation:

$$\tfrac{1}{2}(m + m)v_{SM-MJ}^2 = (m + m)gy_f \quad \text{or} \quad y_f = \frac{v_{SM-MJ}^2}{2g}$$

Solve and evaluate We can work backward to find the maximum height they will reach:

$$y_f = \frac{v_{SM-MJ}^2}{2g} = \frac{[(1/2)v_{SM}]^2}{2g} = \frac{v_{SM}^2}{4 \times 2g} = \frac{y_i}{4}$$

Therefore, they will rise to only a quarter of Jane's original height, or $(10\text{ m})/4 = 2.5$ m—too low to reach the terrace that is 5 m up on the other side of the street. The units are correct. Why is the answer so small? It turns out that half the initial gravitational potential energy is converted to internal energy during the collision.



Try it yourself Suppose Mary Jane's mass is half Spiderman's mass. Would there be more, less, or the same mechanical energy converted into internal energy during the collision?

Answer Using the same process as above except with Mary Jane's mass $m/2$ instead of m, we find that the final height of Spiderman and Mary Jane is $4/9$ of the initial height, or about 4.4 m. Therefore, there is less mechanical energy converted into internal energy during this collision.

REVIEW QUESTION 7.7 Imagine that a collision occurs. You measure the masses of the two objects before the collision and measure the velocities of the objects both before and after the collision. Describe how you could use these data to determine which type of collision had occurred.

7.8 Power

FIGURE 7.15 Walking or running up stairs.

Why is it harder for a person to run up a flight of stairs than to walk up the stairs if the change in gravitational potential energy of the system person-Earth is the same? The *amount* of internal energy converted into gravitational energy is the same in both cases (as shown in **Figure 7.15**), but the *rate* of that conversion is not. When you run upstairs, you convert the energy at a faster rate. The rate at which the conversion occurs is called the **power**.

Power The power of a process is the amount of some type of energy converted into a different type divided by the time interval Δt in which the process occurred:

$$\text{Power} = P = \left|\frac{\Delta E}{\Delta t}\right| \tag{7.9}$$

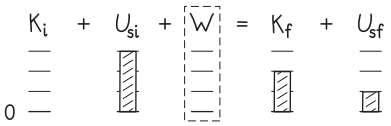
If the process involves external forces doing work, then power can also be defined as the magnitude of the work W done on or by the system divided by the time interval Δt needed for that work to be done:

$$\text{Power} = P = \left|\frac{W}{\Delta t}\right| \tag{7.10}$$

The SI unit of power is the watt (W). 1 watt is 1 joule/second $(1\text{ W} = 1\text{ J/s})$.

A cyclist in good shape pedaling at moderate speed will convert about 400–500 J of internal chemical energy each second (400–500 W) into kinetic, gravitational potential, and thermal energies.

Power is sometimes expressed in *horsepower* (hp): 1 hp = 746 W. Horsepower is most often used to describe the power rating of engines or other machines. A 50-hp gasoline engine (typical in cars) converts the internal energy of the fuel into other forms of energy at a rate of 50 × 746 W = 37,300 W, or 37,300 J/s.



EXAMPLE 7.11 Car power

Miguel and Sierra are investigating a new toy car. The 350-g car is powered by a spring-based engine that delivers approximately constant power. They measure the time dependence of the speed of the car using a motion detector; their data are shown in the table at right. Estimate the power of the spring-based engine during the motion represented in the table. Indicate any assumptions that you made.

t (s)	v (m/s)
0.00	0
0.25	2.4
0.50	3.4
0.75	4.1
1.00	4.8

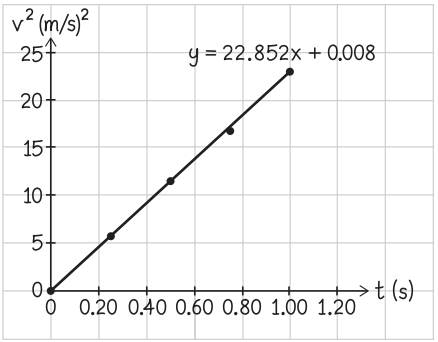
Sketch and translate We choose the car as the system. The initial state is at time $t = 0$ when the car starts moving from rest, and the final state is the moment at some later time t when the car is moving with the speed v.

Simplify and diagram Inside the car's engine, the elastic potential energy of the spring is converted into the kinetic energy of the car. There are two external forces that are exerted on the car, but neither of them does any work on the car. The force exerted by Earth on the car is perpendicular to the displacement of the car, and the point where the ground exerts a force on the car has zero displacement with respect to the car (the part of the car that is in contact with the ground is the tire—if it rolls without slipping, the point of contact is stationary). Ignoring air resistance and any friction in bearings, the work-energy bar chart for the process is shown at right.

Represent mathematically We can express the power of the conversion of elastic potential energy into kinetic energy using the definition of power [see Eq. (7.9)]:

$$P = \left|\frac{\Delta E}{\Delta t}\right| = \frac{\frac{1}{2}mv^2 - 0}{t - 0} = \frac{mv^2}{2t}$$

Solve and evaluate We know the mass of the car (0.350 kg), and we have five data points for t and the corresponding values of v. We want to estimate the unknown power P. Could we just pick one pair of data (t, v) from the table and calculate P using the equation above? We could, but we would discard valuable information that is hidden in the other data points that we did not use. Note that each measurement in the table contains random uncertainties, inherent to all measurements. The more data we use, the more precise our result will be. How can we use all data in the table?



First, we rearrange the previous equation to express v as a function of t, as suggested in the table. We obtain

$$v = \sqrt{\frac{2Pt}{m}}$$

This equation suggests that the speed of the car powered by a constant-power engine is directly proportional to the square root of time. Since we are much more familiar with linear functions and have the tools to analyze them, we square both sides of this equation to obtain a linear dependence on time t:

$$v^2 = \frac{2P}{m}t$$

Next, we draw a graph by plotting the t values on the horizontal axis and the v^2 values on the vertical axis. The best-fit line through the points has a slope equal to 22.9 m^2/s^3.

Since the slope of the line is given by $\frac{2P}{m}$, we can finally calculate the power:

$$P = \frac{(22.9\ \text{m}^2/\text{s}^3)(0.35\ \text{kg})}{2} = 4.0\ \frac{\text{m}\cdot\text{kg}\cdot\text{m}/\text{s}^2}{\text{s}} = 4.0\ \text{W}$$

The units are correct. The qualitative dependence also makes sense: a heavier car with the same (t, v) data would need a more powerful engine. The actual power is probably larger than 4 W since we neglected air resistance and friction in the bearings.

Try it yourself A 1400-kg car is traveling on a level road at a constant speed of 27 m/s (60 mph). The drag force exerted by the air on the car and the rolling friction force exerted by the road on the car tires add to give a net force of 680 N pointing opposite the direction of motion of the car. Determine the rate of work done by the drag and rolling friction forces. Express your results in watts and in horsepower.

Answer $P = 1.8 \times 10^4\ \text{W} = 24\ \text{hp}$

REVIEW QUESTION 7.8 Toyota says that the power of their Prius car is 121 hp. What does this number mean?

7.9 Improving our model of gravitational potential energy

So far, we have assumed that the gravitational force exerted by Earth on an object is constant ($F_{\text{E on O}} = mg$). Using this equation we devised the expression for the gravitational potential energy of an object-Earth system as $U_g = mgy$ (with respect to a chosen zero level). This expression is only valid when an object is close to Earth's surface. We know from our study of gravitation (at the end of Chapter 5) that the gravitational force exerted by planetary objects on moons and satellites and by the Sun on the planets changes with the distance between the objects according to Newton's law of gravitation ($F_{1\text{ on }2} = Gm_1m_2/r^2$). How would the expression for the gravitational potential energy change when we take into account that the gravitational force varies with distance?

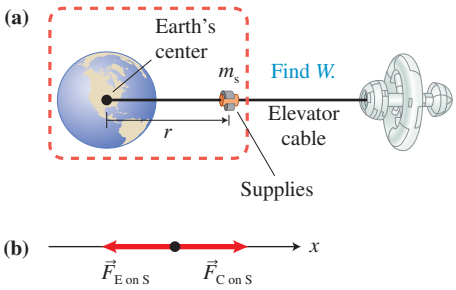
Gravitational potential energy for large separations between objects

Imagine that a "space elevator" has been built to transport supplies from the surface of Earth to the International Space Station (ISS). The elevator moves at constant velocity, except for the very brief acceleration and deceleration at the beginning and end of the trip. How much work must be done to lift the supplies from the surface to the ISS?

The initial state is the moment just as the supplies leave the surface. The final state is the moment just as they arrive at the ISS (**Figure 7.16a**). We choose Earth and the supplies as the system. The force that the elevator cable exerts on the supplies is an external force that does positive work on the system. We keep track of gravitational potential energy only; it is the only type of energy that changes between the initial and final states. Since the supplies are moving at constant velocity, the force exerted by the elevator cable on the supplies is equal in magnitude to the gravitational force exerted by Earth on the supplies (Figure 7.16b). Earth is the object of reference, and the origin of the coordinate system is at the center of Earth. The process can be described mathematically as follows:

$$U_{\text{gi}} + W = U_{\text{gf}} \Rightarrow W = U_{\text{gf}} - U_{\text{gi}}$$

At this point it would be tempting to say that the work done by the elevator cable on the system is $W = Fd\cos\theta$, where F is the constant force that the cable exerts on the supplies. However, as the supplies reach higher and higher altitudes, the force exerted by the elevator cable decreases—Earth exerts a weaker and weaker force on the supplies.



Determining the work done by a variable force requires a complex mathematical procedure. The outcome of this procedure is

$$W = \left(-G\frac{m_{\text{E}}m_{\text{S}}}{R_{\text{E}} + h_{\text{ISS}}}\right) - \left(-G\frac{m_{\text{E}}m_{\text{S}}}{R_{\text{E}}}\right)$$

where m_{E} is the mass of Earth, R_{E} is the radius of Earth, m_{S} is the mass of the supplies, h_{ISS} is the altitude of the ISS above Earth's surface, and $R_{\text{E}} + h_{\text{ISS}}$ is the distance of the ISS from the center of Earth. Before you move on, check whether this complicated equation makes sense (for example, check the units).

The work is written as the difference in two quantities; the latter describes the initial state and the former the final state. If we compare the above result with $W = U_{\text{gf}} - U_{\text{gi}}$, we see that each term is an expression for the gravitational potential energy of the Earth-object system for a particular object's distance from the center of Earth.

FIGURE 7.16 A cable lifts supplies to the International Space Station via a space elevator. (a) Determine the work required to lift the supplies. (b) The cable exerts the force in the direction of motion. In this force diagram, the supplies are the system.

Gravitational potential energy of a system consisting of Earth and any object

$$U_g = -G\frac{m_E m_O}{r_{E\text{-}O}} \tag{7.11}$$

where m_E is the mass of Earth (5.97×10^{24} kg), m_O is the mass of the object, $r_{E\text{-}O}$ is the distance from the center of Earth to the center of the object, and $G = 6.67 \times 10^{-11}\,\text{N}\cdot\text{m}^2/\text{kg}^2$ is Newton's gravitational constant.

We can use Eq. (7.11) to find the gravitational potential energy of the system of any two spherical or point-like objects if we know the masses of the objects and the distance between their centers.

Note that the cable did positive work on the system while pulling the supplies away from Earth. When the object (the supplies in this case) is infinitely far away, the gravitational potential energy is zero. The only way to add positive energy to a system and have it become zero is if it started with negative energy, for example, $-5 + 5 = 0$. Thus, for the case of zero energy at infinity, the gravitational potential energy is a negative number when the object is closer to Earth. We can represent the process of pulling an object from the surface of Earth to infinity using a work-energy bar chart (**Figure 7.17**). The initial state is when the object is near Earth, and the final state is when it is infinitely far away.

Now we can determine the amount of work needed to raise 1000 kg of supplies to the International Space Station, which is 3.50×10^5 m above Earth's surface.

$$\begin{aligned} W &= \left(-G\frac{m_E m_S}{R_E + h_{ISS}}\right) - \left(-G\frac{m_E m_S}{R_E}\right) \\ &= -Gm_E m_S\left(\frac{1}{R_E + h_{ISS}} - \frac{1}{R_E}\right) \\ &= -(6.67 \times 10^{-11}\,\text{N}\cdot\text{m}^2/\text{kg}^2)(5.97 \times 10^{24}\,\text{kg})(1000\,\text{kg}) \\ &\quad \times \left(\frac{1}{6.37 \times 10^6\,\text{m} + 3.50 \times 10^5\,\text{m}} - \frac{1}{6.37 \times 10^6\,\text{m}}\right) \\ &= 3.26 \times 10^9\,\text{J} \end{aligned}$$

Let's compare this with what would have been calculated had we used our original expression for gravitational potential energy. Choose the zero level at the surface of Earth.

$$\begin{aligned} W = m_S g y_f - m_S g y_i &= m_S g y_f - 0 \\ &= (1000\,\text{kg})(9.8\,\text{N/kg})(3.50 \times 10^5\,\text{m}) = 3.43 \times 10^9\,\text{J} \end{aligned}$$

This differs by only about 5% from the more accurate result. Remember that $U_g = mgy$ is reasonable when the distance above the surface of Earth is a small fraction of the radius of Earth. The altitude of the ISS (350 km) is a small fraction of the radius of Earth (6371 km), so $U_g = mgy$ is still reasonably accurate.

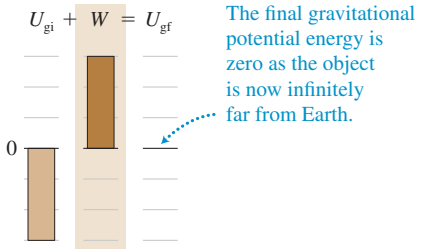


FIGURE 7.17 A bar chart representing the work needed to take an object from near Earth to infinitely far away. The system is the supplies and Earth.

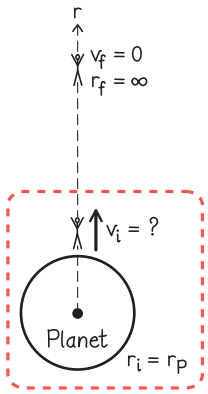
Escape speed

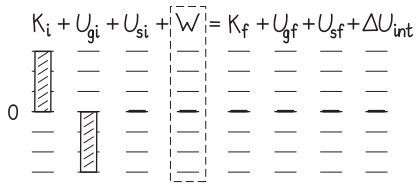
The best Olympic high jumpers can leap over bars that are about 2.5 m (8 ft) above Earth's surface. Let's estimate a jumper's speed when leaving the ground in order to attain that height. We choose the jumper and Earth as the system and the zero level of gravitational potential energy at ground level. The kinetic energy of the jumper as he leaves the ground is converted into the gravitational potential energy of the system.

$$\begin{aligned} \tfrac{1}{2}mv^2 &= mgy \\ \Rightarrow v = \sqrt{2gy} &= \sqrt{2(9.8\,\text{N/kg})(2.5\,\text{m})} = 7.0\,\text{m/s} \end{aligned}$$



The gravitational coefficient of objects near the Moon's surface is $g_M = \frac{Gm_M}{R_M^2} = 1.6\ \text{N/kg}$. Using the equation above, we find the height of the jump to be 15.3 m. That's about 50 feet!

Is it possible to jump entirely off a celestial body—that is, jump up and never come down? What is the minimum speed you would need in order to do this? This minimum speed is called **escape speed**.



EXAMPLE 7.12 **Escape speed**

What vertical speed must a jumper have in order to leave the surface of a planet and never come back down?

Sketch and translate First, we draw a sketch of the process. The initial state is the instant after the jumper's feet leave the surface. The final state is when the jumper has traveled far enough away from the planet to no longer feel the effects of its gravity (at $r = \infty$). Choose the system to be the jumper and the planet.

Simplify and diagram We represent the process with the bar chart. In the initial state, the system has both kinetic and gravitational potential energy. In the final state, both the kinetic energy and the gravitational potential energy are zero.

Represent mathematically Using the generalized work-energy equation and the bar chart:

$$E_i + W = E_f$$
$$\Rightarrow K_i + U_{gi} + 0 = K_f + U_{gf}$$
$$\Rightarrow \tfrac{1}{2}m_J v^2 + \left(-G\frac{m_P m_J}{r_P}\right) + 0 = 0 + 0$$

where m_P is the mass of the planet, m_J is the mass of the jumper, r_P is the radius of the planet, and $G = 6.67 \times 10^{-11}\ \text{N} \cdot \text{m}^2/\text{kg}^2$ is the gravitational constant.

Solve and evaluate Solving for the escape speed of the jumper,

$$v = \sqrt{\frac{2Gm_P}{r_P}} \tag{7.12}$$

We can use the above equation to determine the escape speed for any celestial body. For example, the escape speed for the Moon is

$$v = \sqrt{\frac{2(6.67 \times 10^{-11}\ \text{N} \cdot \text{m}^2/\text{kg}^2)(7.35 \times 10^{22}\ \text{kg})}{1.74 \times 10^6\ \text{m}}}$$
$$= 2370\ \text{m/s}$$

The escape speed for Earth is

$$v = \sqrt{\frac{2Gm_E}{R_E}}$$
$$= \sqrt{\frac{2(6.67 \times 10^{-11}\ \text{N} \cdot \text{m}^2/\text{kg}^2)(5.97 \times 10^{24}\ \text{kg})}{6.37 \times 10^6\ \text{m}}}$$
$$= 11{,}200\ \text{m/s} = 11.2\ \text{km/s}$$

Try it yourself What is the escape speed of a particle near the surface of the Sun? The mass of the Sun is 2.0×10^{30} kg and its radius is 700,000 km.

Answer 620 km/s.

TIP Notice that the escape speed does not depend on the mass of the escaping object—a tiny speck of dust and a huge boulder would need the same initial speed to leave Earth. Why is that?

Black holes

Equation (7.12) for the escape speed suggests something amazing. If the mass of a star were large enough and/or its radius small enough, the escape speed could be made arbitrarily large. What if the star's escape speed were greater than light speed ($c = 3.00 \times 10^8\ \text{m/s}$)? What would this star look like? Light leaving the star's surface would not be moving fast enough to escape the star. The star would be completely dark.

Let's imagine what would happen if the Sun started shrinking so that its material were compressed into a smaller volume. How small would the Sun have to be for its

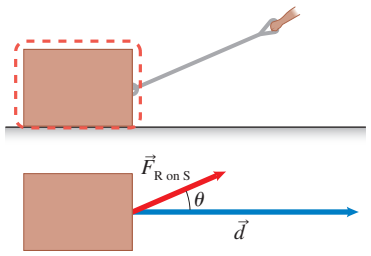
escape speed to be greater than light speed? Use Eq. (7.12) with $v = c$ to answer this question.

$$v = c = \sqrt{\frac{2Gm_S}{r_S}} \tag{7.13}$$

or

$$r_S = \frac{2Gm_S}{c^2} = \frac{2(6.67 \times 10^{-11}\,\mathrm{N \cdot m^2/kg^2})(1.99 \times 10^{30}\,\mathrm{kg})}{(3.00 \times 10^8\,\mathrm{m/s})^2}$$
$$= 2.95 \times 10^3\,\mathrm{m} \approx 3\,\mathrm{km}$$

So, if the Sun collapsed to smaller than 3 km in radius, it would become invisible for the outside world. Could this happen? We will return to this question in later chapters.



Equation (7.13) was first constructed by the brilliant astronomer Pierre-Simon Laplace (1749–1827), who used classical mechanics to predict the presence of what he called "dark stars"—now more commonly called black holes.

We've been talking about objects whose escape speed is larger than light speed. Physicists once thought that since light has zero mass, the gravitational force exerted on it would always be zero. At the beginning of the 20th century, Albert Einstein's theory of general relativity improved greatly on Newton's law of universal gravitation. According to general relativity, light is affected by gravity. Amazingly, the theory predicts the same size for a black hole that is provided by the Newtonian theory.

REVIEW QUESTION 7.9 In this section you read that the gravitational potential energy of two large bodies (for example, the Sun and Earth) is negative. Why is this true?

Summary

Work (W) is a way to change the energy of a system. Work is done on a system when an external object exerts a force of magnitude F on an object in the system as it undergoes a displacement of magnitude d. The work depends on the angle θ between the directions of $\vec{F}$ and $\vec{d}$. It is a scalar quantity. (Section 7.1)

$$W = Fd\cos\theta \qquad \text{Eq. (7.1)}$$

Gravitational potential energy (U_g) is the energy that a system has due to the relative separation of two objects with mass. It is a scalar quantity. U_g depends on the gravitational interaction of the objects. A single object cannot have gravitational potential energy.

$$U_g = mgy \qquad \text{Eq. (7.4)}$$

(near Earth's surface; zero level is at the surface)

$$U_g = -G\frac{m_A m_B}{r_{AB}} \qquad \text{Eq. (7.11)}$$

(general expression; zero level is at infinity)

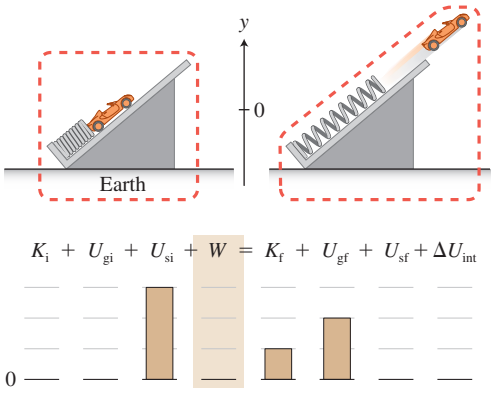
Kinetic energy (K) is the energy of an object of mass m moving at speed v. It is a scalar quantity.

$$K = \tfrac{1}{2}mv^2 \qquad \text{Eq. (7.5)}$$

Elastic potential energy (U_s) is the energy of a stretched or compressed elastic object (e.g., coils of a spring or a stretched bow string).

$$U_s = \tfrac{1}{2}kx^2 \qquad \text{Eq. (7.7)}$$

Internal energy (U_{int}) is the energy of motion and interaction of the microscopic particles making up the objects in the system. (Section 7.1)



$$\Delta U_{int} = +f_k d \qquad \text{Eq. (7.8)}$$

(conversion of mechanical energy to internal due to friction)

Total energy (E) is the sum of all the energies of the system. (Section 7.2)

$$E = K + U_g + U_s + U_{int} + \cdots \qquad \text{Eq. (7.2)}$$

Work-energy principle The energy of a system changes when external forces do work on it. Internal forces do not change the energy of the system. When there are no external forces doing work on the system, the system's energy is constant. (Section 7.2)

$$E_i + W = E_f \qquad \text{Eq. (7.3)}$$

$$(K_i + U_{gi} + U_{si}) + W = (K_f + U_{gf} + U_{sf} + \Delta U_{int})$$

Collisions

- **Elastic:** momentum and kinetic energy of the system are constant—no changes in internal energy.
- **Inelastic:** momentum is constant but kinetic energy is not—internal energy increases and kinetic energy decreases.
- **Totally inelastic:** an inelastic collision in which the colliding objects stick together. (Section 7.7)

All collisions:

$$\Sigma\vec{p}_i = \Sigma\vec{p}_f$$

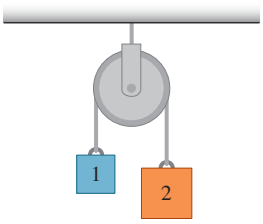
Elastic collisions only:

$$\Sigma K_i = \Sigma K_f$$

For other collisions,

$$\Delta U_{int} > 0$$

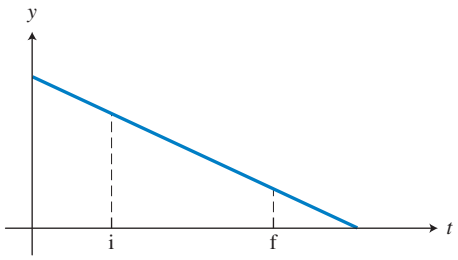
Power (P) is the rate of energy conversion, or rate of work done on a system during a process. (Section 7.8)



$$P = \left|\frac{\Delta E}{\Delta t}\right| \text{ or } P = \left|\frac{W}{\Delta t}\right| \qquad \text{Eq. (7.9) or (7.10)}$$

Questions

Multiple Choice Questions



1. In which of the following is positive work done by a person on a suitcase?
   (a) The person holds a heavy suitcase.
   (b) The person lifts a heavy suitcase.
   (c) The person stands on a moving walkway carrying a heavy suitcase.
   (d) All of the above
   (e) None of the above
2. Which answer best represents the system's change in energy for the following process? The system includes Earth, two carts, and a compressed spring between the carts. The spring is released, and in the final state, one cart is moving up a frictionless ramp until it stops. The other cart is moving in the opposite direction on a horizontal frictionless track.
   (a) Kinetic energy to gravitational potential energy
   (b) Elastic potential energy to gravitational potential energy
   (c) Elastic potential energy to kinetic energy and gravitational potential energy
   (d) Elastic potential energy to kinetic energy
3. An Atwood machine is shown in **Figure Q7.3**. As the blocks are released and block 1 moves downward, the energy of the block 1-Earth system
   (a) increases.
   (b) decreases.
   (c) stays constant.
   (d) It's impossible to say without including block 2 in the system.

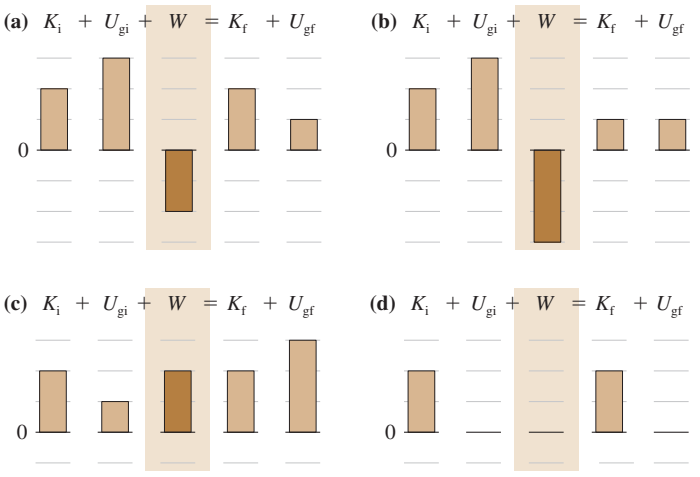


FIGURE Q7.3

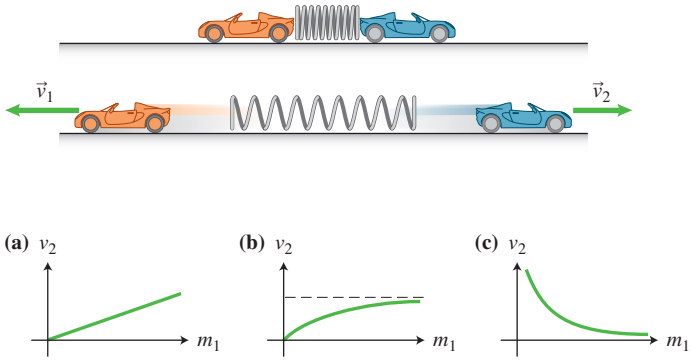
4. Below you see several statements analyzing the process described in the previous question. Match the energy analysis with the system choice for which the analysis is correct.
   I. The total energy of the system decreases.
   II. The total energy of the system increases.
   III. The total energy of the system stays constant.
   Systems:
   (a) Block 2 and Earth
   (b) Block 1 and Earth
   (c) Both blocks, the string, and Earth
   (d) Both blocks and the string
5. Three processes are described below. Choose one process in which there is work done on the system. The spring, Earth, and the cart are part of the system.
   (a) A relaxed spring rests upright on a tabletop. You slowly compress the spring. You then release the spring and it flies up several meters to its highest point.
   (b) A cart at the top of a smooth inclined surface coasts at increasing speed to the bottom (ignore friction).
   (c) A cart at the top of a smooth inclined surface slides at increasing speed to the bottom where it runs into and compresses a spring (ignore friction).
6. Choose which statement describes a process in which an external force does negative work on the system. The person is not part of the system.
   (a) A person slowly lifts a box from the floor to a tabletop.
   (b) A person slowly lowers a box from a tabletop to the floor.
   (c) A person carries a bag of groceries horizontally from one location to another.
   (d) A person holds a heavy suitcase.
7. Which example(s) below involve(s) zero physics work? Choose all that apply.
   (a) A person holds a child.
   (b) A person pushes a car stuck in the snow but the car does not move.
   (c) A rope supports a swinging chandelier.
   (d) A person uses a self-propelled lawn mower on a level lawn.
   (e) A person pulls a sled uphill.
8. Estimate the change in gravitational potential energy when you rise from bed to a standing position.
   (a) No change (0 J)
   (b) About 250 J
   (c) About 2500 J
   (d) About 25 J
9. What does it mean if object 1 does +10 J of work on object 2?
   (a) Object 1 exerts a 10-N force on object 2 in the direction of its 1-m displacement.
   (b) Object 1 exerts a 1-N force on object 2 in the direction of its 10-m displacement.
   (c) Object 1 exerts a 10-N force on object 2 at a 60° angle relative to its 2-m displacement.
   (d) All of the above
   (e) None of the above
10. You pull on a spring, which obeys Hooke's law, in two steps. In step 1, you extend it by distance x_s. In step 2, you further extend it by the same distance x_s. Choose the answer that correctly compares the elastic potential energy of the spring after the first step (U_{s1}) with that after the second step (U_{s2}).
    (a) $U_{s2} = 2U_{s1}$ because the force exerted on the spring at the end of step 2 is two times larger than at the end of step 1.
    (b) $U_{s2} = 2U_{s1}$ because the extension of the spring at the end of step 2 is two times larger than the extension of the spring at the end of step 1.
    (c) $U_{s2} > 2U_{s1}$ because the more the spring is stretched, the larger the force that is needed to extend the spring for a unit distance.
    (d) $U_{s2} > 2U_{s1}$ because the average force exerted on the spring in step 2 is more than two times larger than the average force exerted on the spring in step 1.
11. The graph in **Figure Q7.11** shows the time dependence of the vertical displacement of a lead ball with marked initial and final states. Choose all the work-energy bar charts (a) to (d) that can represent this process (multiple answers may be correct). Note that the y-axis can point either up or down.

FIGURE Q7.11



12. A 1400-kg car is traveling on a level road at a constant speed of 60 mi/h. The drag force exerted by the air on the car and the rolling friction force exerted by the road on the car tires add to give a net force of 680 N pointing opposite to the direction of the car's motion. What is the rate of work done by the air and the road on the car?
    (a) 820 kW
    (b) 370 kW
    (c) 41 kW
    (d) 18 kW

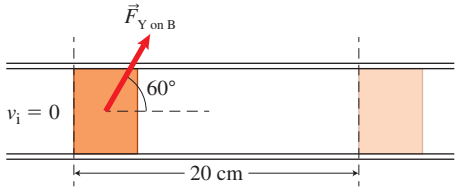
13. You place two toy cars on a horizontal table and connect them with a light compressed spring as shown in **Figure Q7.13**. The spring tries to push the cars apart, but they are tied together by a thread. When the thread is burned, the spring pushes the cars apart. You decide to investigate how the final speed of car 2 depends on the mass of car 1. You run several experiments changing m_1 and measuring v_2 while keeping the compression of the spring and the mass of car 2 constant. Which of the v_2-versus-m_1 graphs (a) to (c) do you expect to obtain? Evaluate the graphs by analyzing limiting cases.

FIGURE Q7.13

14. Two clay balls are moving toward each other. The balls have equal kinetic energies ($K_1 = K_2$), but ball 1, which is coming from the left, is moving faster than ball 2 ($v_1 > v_2$). Which answer correctly explains how the balls will move after a totally inelastic collision?
    (a) The balls will not move because $K_1 = K_2$ before the collision.
    (b) The balls will move to the left because $p_2 > p_1$ before the collision.
    (c) The balls will move to the right because $v_1 > v_2$ before the collision.
    (d) We cannot predict how the balls will move after the collision.

Conceptual Questions

15. Is energy a physical phenomenon, a model, or a physical quantity? Explain your answer.
16. Your friend thinks that the escape speed should be greater for more massive objects than for less massive objects. Provide an argument for his opinion. Then provide a counterargument for why the escape speed is independent of the mass of the object.
17. Suggest how you can measure the following quantities: the power of a motor, the kinetic energy of a moving car, and the elastic potential energy of a stretched spring.
18. How can satellites stay in orbit without any jet propulsion system? Explain using work-energy ideas.
19. Why does the Moon have no atmosphere, but Earth does?
20. What will happen to Earth if our Sun becomes a black hole?
21. In the equation $U_g = mgy$, the gravitational potential energy is directly proportional to the distance of the object from a planet. In the equation $U_g = -G\dfrac{m_p m}{r}$, it is inversely proportional. How can you reconcile those two equations?
22. You push a small cart by exerting a constant force F along a table. After you push the cart a distance s, the cart falls off the table and lands on the floor a distance D_1 away from the table edge. You repeat the same experiment (same F, same s) using a heavier cart and obtain a new distance D_2. Choose the answer that correctly compares the distances D_1 and D_2 and gives the best explanation of the outcome.
    (a) $D_1 = D_2$ because the same work was done on both carts before they flew off the table.
    (b) $D_1 = D_2$ because the carts had the same momentum before they flew off the table.
    (c) $D_1 > D_2$ because the carts had the same kinetic energy before they flew off the table, and consequently the speed of the lighter cart had been greater.
    (d) $D_1 > D_2$ because the kinetic energy of cart 1 had been greater than that of cart 2 before they flew off the table.



Problems

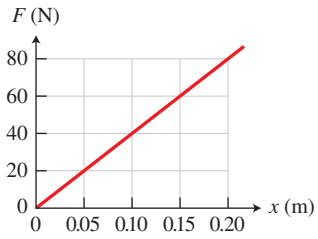
Below, BIO indicates a problem with a biological or medical focus. Problems labeled EST ask you to estimate the answer to a quantitative problem rather than derive a specific answer. Asterisks indicate the level of difficulty of the problem. Problems with no * are considered to be the least difficult. A single * marks moderately difficult problems. Two ** indicate more difficult problems.

7.1 Work and energy

1. Jay fills a wagon with sand (about 20 kg) and pulls it with a rope 30 m along the beach. He holds the rope 25° above the horizontal. The rope exerts a 20-N tension force on the wagon. How much work does the rope do on the wagon?
2. You have a 15-kg suitcase and (a) slowly lift it 0.80 m upward, (b) hold it at rest to test whether you will be able to move the suitcase without help in the airport, and then (c) lower it 0.80 m. What work did you do in each case? What assumptions did you make to solve this problem?
3. * You use a rope to slowly pull a sled and its passenger 50 m up a 20° incline, exerting a 150-N force on the rope. The system is the sled. (a) How much work will you do if you pull parallel to the incline? (b) How much work will you do if you exert the same magnitude force while slowly lowering the sled back down the incline and pulling parallel to the incline? (c) How much work did Earth do on the sled for the trip in part (b)?
4. A rope attached to a truck pulls a 180-kg motorcycle at 9.0 m/s. The rope exerts a 400-N force on the motorcycle at an angle of 15° above the horizontal. (a) What is the work that the rope does in pulling the motorcycle 300 m? (b) How will your answer change if the speed is 12 m/s? (c) How will your answer change if the truck accelerates?
5. You lift a 25-kg child 0.80 m, slowly carry him 10 m to the playroom, and finally set him back down 0.80 m onto the playroom floor. What work do you do on the child for each part of the trip and for the whole trip? List your assumptions.
6. A truck runs into a pile of sand, moving 0.80 m as it slows to a stop. The magnitude of the work that the sand does on the truck is 6.0×10^5 J. (a) Determine the magnitude of the average force that the sand exerts on the truck. (b) Did the sand do positive or negative work? (c) How does the average force change if the stopping distance is doubled? Indicate any assumptions you made.
7. A 0.50-kg block is placed in a straight gutter that allows the block to move only along the gutter. The friction between the gutter walls and the block is negligible. You are exerting a constant force of 3.0 N on the block at an angle of 60° with respect to the gutter (**Figure P7.7** shows the top view). The block is initially at rest. Determine (a) the work done on the block if the distance it moved is 20 cm and (b) the final speed of the block.

FIGURE P7.7

8. ** You are pushing a block of mass m at constant speed v over distance s up a smooth incline, which makes an angle θ with the horizontal. (a) Derive an expression for the work done by Earth on the block. (b) How would the answer to part (a) change if there is friction between the block and the incline? (c) How would the answer to part (a) change if you are pushing the block so that it is speeding up but there is no friction between the block and the incline?
9. ** It is a windy day. You are moving a 20-kg box at a constant speed over 10 m by pulling a rope that is attached to the box. The rope makes an angle of 25° with the horizontal. The coefficient of friction between the box and the ground is 0.4. The force exerted by the wind on the box is 15.0 N. Determine the work done by you on the box if (a) the wind is blowing toward you and (b) if the wind is blowing on your back.



7.2 and 7.3 Energy is a conserved quantity and Quantifying gravitational potential and kinetic energies

10. A 5.0-kg rabbit and a 12-kg Irish setter have the same kinetic energy. If the setter is running at speed 4.0 m/s, how fast is the rabbit running?
11. * EST Estimate your average kinetic energy when walking to physics class. What assumptions did you make?
12. * A pickup truck (2268 kg) and a compact car (1100 kg) have the same momentum. (a) What is the ratio of their kinetic energies? (b) If the same horizontal net force were exerted on both vehicles, pushing them from rest over the same distance, what is the ratio of their final kinetic energies?
13. * When does the kinetic energy of a car change more: when the car accelerates from 0 to 10 m/s or from 30 m/s to 40 m/s? Explain.
14. * When exiting the highway, a 1100-kg car is traveling at 22 m/s. The car's kinetic energy decreases by 1.4×10^5 J. The exit's speed limit is 35 mi/h. Did the driver reduce the car's speed enough? Explain.
15. * You are on vacation in San Francisco and decide to take a cable car to see the city. A 5200-kg cable car goes 360 m up a hill inclined 12° above the horizontal. The system is the car and Earth. Determine the change in the total energy of the system when the car moves from the bottom to the top. Indicate any assumptions that you made.
16. * **Flea jump** A 5.4×10^{-7}-kg flea pushes off a surface by extending its rear legs for a distance of slightly more than 2.0 mm, consequently jumping to a height of 40 cm. What physical quantities can you determine using this information? Make a list and determine three of them.
17. * **Roller coaster ride** A roller coaster car drops a maximum vertical distance of 35.4 m. (a) Determine the maximum speed of the car at the bottom of that drop. (b) Describe any assumptions you made. (c) Will a car with twice the mass have more or less speed at the bottom? Explain.
18. * BIO EST **Heart pumps blood** The heart does about 1 J of work while pumping blood into the aorta during each heartbeat. (a) Estimate the work done by the heart in pumping blood during a lifetime. (b) If all of that work was used to lift a person, to what height could an average person be lifted? Indicate any assumptions you used for each part of the problem.
19. * **Wind energy** Air circulates across Earth in regular patterns. A tropical air current called the Hadley cell carries about 2×10^{11} kg of air per second past a cross section of Earth's atmosphere while moving toward the equator. The average air speed is about 1.5 m/s. (a) What is the kinetic energy of the air that passes the cross section each second? (b) About 1×10^{20} J of energy was consumed in the United States in 2005. What is the ratio of the kinetic energy of the air that passes toward the equator each second and the energy consumed in the United States each second?
20. * BIO **Bone break** The tibia bone in the lower leg of an adult human will break if the compressive force on it exceeds about 4×10^5 N (we assume that the ankle is pushing up). Suppose that a student of mass 60 kg steps off a chair that is 0.40 m above the floor. If landing stiff-legged on the surface below, what minimum stopping distance does he need to avoid breaking his tibias? Indicate any assumptions you made in your answer to this question.
21. * BIO EST **Climbing Mt. Everest** In 1953 Sir Edmund Hillary and Tenzing Norgay made the first successful ascent of Mt. Everest. How many slices of bread did each climber have to eat to compensate for the increase of the gravitational potential energy of the system climbers-Earth? (One piece of bread releases about 1.0×10^6 J of energy in the body.) Indicate all of the assumptions used. Note: The body is an inefficient energy converter—see the reading passage at the end of this section.

7.4 Quantifying elastic potential energy

22. A door spring is difficult to stretch. (a) What maximum force do you need to exert on a relaxed spring with a 1.2×10^4-N/m spring constant to stretch it 6.0 cm from its equilibrium position? (b) How much does the elastic potential energy of the spring change? (c) Determine its change in elastic potential energy as it returns from the 6.0-cm stretch position to a 3.0-cm stretch position. (d) Determine its elastic potential energy change as it moves from the 3.0-cm stretch position back to its equilibrium position.
23. * A moving car has 40,000 J of kinetic energy while moving at a speed of 7.0 m/s. A spring-loaded automobile bumper compresses 0.30 m when the car hits a wall and stops. What can you learn about the bumper's spring using this information? Answer quantitatively and list the assumptions that you made.
24. * The force required to stretch a slingshot by different amounts is shown in the graph in **Figure P7.24**. (a) What is the spring constant of the sling? (b) How much work does a child need to do to stretch the sling 15 cm from equilibrium?

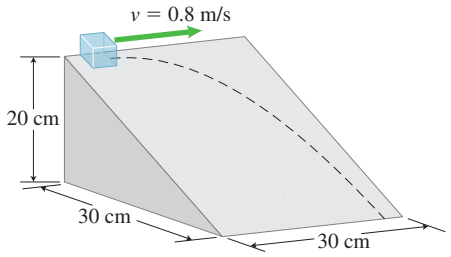
FIGURE P7.24

7.5 Friction and energy conversion

25. Jim is driving a 2268-kg pickup truck at 20 m/s and releases his foot from the accelerator pedal. The car eventually stops due to an effective friction force that the road, air, and other things exert on the car. The friction force has an average magnitude of 800 N. Determine the stopping distance of the truck.
26. * A car skids 18 m on a level road while trying to stop before hitting a stopped car in front of it. The two cars barely touch. The coefficient of kinetic friction between the first car and the road is 0.80. A policewoman gives the driver a ticket for exceeding the 35 mi/h speed limit. Can you defend the driver in court? Explain.
27. ** A waterslide of length l has a vertical drop of h. Abby's mass is m. An average friction force of magnitude f opposes her motion. She starts down the slide at initial speed v_i. Use work-energy ideas to develop an expression for her speed at the bottom of the slide. Then evaluate your result using unit analysis and limiting case analysis.
28. ** You are pulling a crate on a rug, exerting a constant force on the crate $\vec{F}_{\text{Y on C}}$ at an angle θ above the horizontal. The crate moves at constant speed. Represent this process using a motion diagram, a force diagram, a momentum bar chart, and an energy bar chart. Specify your choice of system for each representation. Make a list of physical quantities you can determine using this information.
29. * Your friend Devin has to solve the following problem: "You have a spring with spring constant k. You compress it by distance x and use it to shoot a steel ball of mass m into a sponge of mass M. After the collision, the ball and the sponge move a distance s along a rough surface and stop (see **Figure P7.29**). The coefficient of friction between the sponge and the surface is μ. Derive an expression that shows how the distance s depends on relevant physical quantities."

FIGURE P7.29

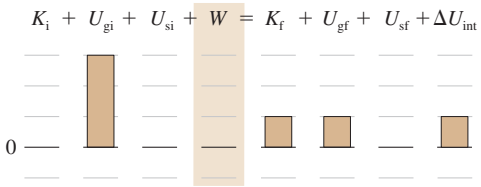
Devin derived the following equation:



$$s = \frac{kmx^2}{2(m + M)^2 g\mu}$$

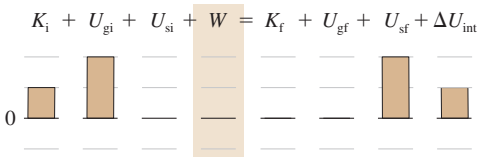
Without deriving it, evaluate the equation that Devin came up with. Is it reasonable? How do you know?

7.6 Skills for analyzing processes using the work-energy principle



30. In a popular new hockey game, the players use small launchers with springs to move the 0.0030-kg puck. Each spring has a 120-N/m spring constant and can be compressed up to 0.020 m. Determine the maximum speed of the puck. First, represent the process with a work-energy bar chart and then solve the problem.
31. The top of a descending ski slope is 50 m higher than the bottom of the slope. A 60-kg skier starts from rest and skis straight to the bottom of the slope. (a) Represent the process with work-energy bar charts. Indicate the system, the initial state, and the final state. (b) Determine the speed of a skier at the bottom of the slope, assuming the friction is negligible. (c) Would a heavier skier have a larger, smaller, or the same speed at the bottom of the slope? Explain.
32. * If 20% of the gravitational potential energy change of the skier in the previous problem is converted into internal energy (due to friction and air drag), how fast is the 60-kg skier traveling at the bottom of the slope? Again, represent the process with work-energy bar charts indicating the system, the initial state, and the final state.
33. You exert a quick push on a 20-g ice cube horizontally along the top of a smooth incline so that it starts moving at a speed of 0.8 m/s, as shown in Figure P7.33. After you stop pushing it, the cube slides down the incline as shown in the figure. Calculate the speed of the ice cube when it reaches the bottom of the incline.

FIGURE P7.33



34. A driver loses control of a car, drives off an embankment, and lands in a canyon 6.0 m below. What was the car's speed just before touching the ground if it was traveling on the level surface at 12 m/s before the driver lost control?
35. * You are pulling a box so it moves at increasing speed. Compare the work you need to do to accelerate it from 0 m/s to speed v to the work needed to accelerate it from speed v to the speed of $2v$. Discuss whether your answer makes sense. How many different situations do you need to consider?
36. ** A cable lowers a 1200-kg elevator so that the elevator's speed increases from zero to 4.0 m/s in a vertical distance of 6.0 m. What is the force that the cable exerts on the elevator while lowering it? Specify the system, its initial and final states, and any assumptions you made. Then change the system and solve the problem again. Do the answers match?
37. ** EST **Hit by a hailstone** A 0.030-kg hailstone the size of a golf ball (4.3 cm in diameter) is falling at about 16 m/s when it reaches Earth's surface. Estimate the force that the hailstone exerts on your head—a head-on collision. Indicate any assumptions used in your estimate. Note that the cheekbone will break if something exerts a 900-N or larger force on the bone for more than 6 ms. Is this hailstone likely to break a bone?
38. * BIO **Froghopper jump** Froghoppers may be the insect jumping champs. These 6-mm-long bugs can spring 70 cm into the air, about the same distance as the flea. But the froghopper is 60 times more massive than a 12-mg flea. The froghopper pushes off for about 4 mm. What average force does it exert on the surface? Compare this to the gravitational force that Earth exerts on the bug.
39. * **Bar chart Jeopardy 1** Describe in words and with a sketch a process that is consistent with the qualitative work-energy bar chart shown in Figure P7.39. Then apply in symbols the generalized work-energy principle for that process.

FIGURE P7.39

40. * **Bar chart Jeopardy 2** Describe in words and with a sketch a process that is consistent with the qualitative work-energy bar chart shown in Figure P7.40. Then apply in symbols the generalized work-energy principle for that process.

FIGURE P7.40

41. * **Equation Jeopardy 1** Construct a qualitative work-energy bar chart for a process that is consistent with the equation below. Then describe in words and with a sketch a process that is consistent with both the equation and the bar chart.

$$(1/2)(400\ \text{N/m})(0.20\ \text{m})^2 = (1/2)(0.50\ \text{kg})v^2 + (0.50\ \text{kg})(9.8\ \text{m/s}^2)(0.80\ \text{m})$$

42. * **Equation Jeopardy 2** Construct a qualitative work-energy bar chart for a process that is consistent with the equation below. Then describe in words and with a sketch a process that is consistent with both the equation and the bar chart.

$$(120\ \text{kg})(9.8\ \text{m/s}^2)(100\ \text{m})\sin 53^\circ = (1/2)(120\ \text{kg})(20\ \text{m/s})^2 + f_k(100\ \text{m})$$

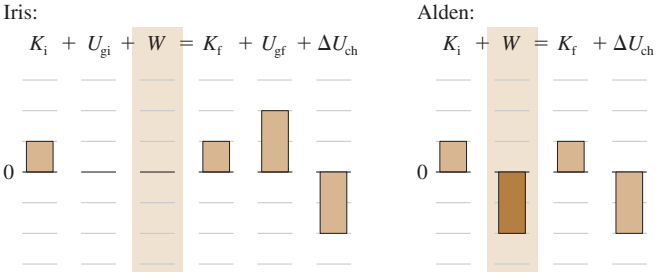
43. * **Evaluation 1** Your friend provides a solution to the following problem. Evaluate his solution. Constructively identify any mistakes he made and correct the solution. Explain possible reasons for the mistakes.

The problem: A 400-kg motorcycle, including the driver, travels up a 10-m-long ramp inclined 30° above the paved horizontal surface holding the ramp. The cycle leaves the ramp at speed 20 m/s. Determine the cycle's speed just before it lands on the paved surface.

Your friend's solution:

$$(1/2)(400\ \text{kg})(20\ \text{m/s}) = (400\ \text{kg})(9.8\ \text{m/s}^2)(10\ \text{m}) + (1/2)(400\ \text{kg})v^2$$
$$v = -13.2\ \text{m/s}$$

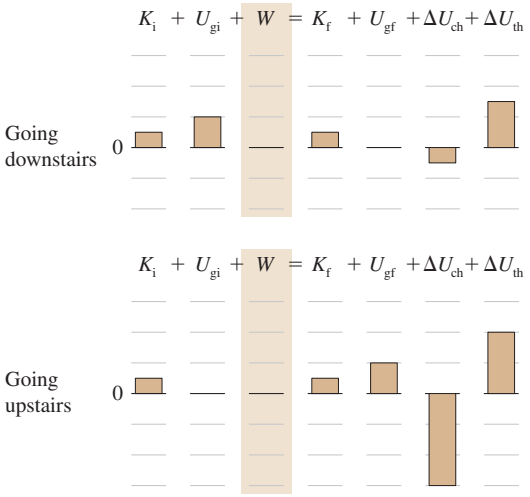
44. * **Evaluation 2** Your friend provides a solution to the following problem. Evaluate her solution. Constructively identify any mistakes she made and correct the solution. Explain possible reasons for the mistakes.



The problem: Jim (mass 50 kg) steps off a ledge that is 2.0 m above a platform that sits on top of a relaxed spring of force constant 8000 N/m. How far will the spring compress while stopping Jim?

Your friend's solution:

$$(50\ \text{kg})(9.8\ \text{m/s}^2)(2.0\ \text{m}) = (1/2)(8000\ \text{N/m})x$$
$$x = 0.25\ \text{m}$$



45. A crab climbs up a vertical rock with a constant speed. Students Iris and Alden represent this process using the work-energy bar charts in Figure P7.45. They choose the same initial and final states but different systems. On both bar charts ΔU_{ch} represents change in chemical energy. The students also assumed that the temperature of the crab did not change. Describe the system and the initial and final states that each student has chosen.

FIGURE P7.45

46. * Work-energy bar charts for a person going downstairs and upstairs are shown in **Figure P7.46**. The bar charts show the average energy conversion across several steps. The system is the person, Earth, and the stairs. (a) What are the initial and final states in each case? (b) Describe and explain the similarities in the bar charts. (c) Describe the differences in the bar charts. How do these differences explain why we are less tired going downstairs? (d) How do you explain that when we walk upstairs $|\Delta U_{th}| < |\Delta U_{ch}|$, but when we walk downstairs $|\Delta U_{th}| > |\Delta U_{ch}|$? (Hint: Think about what happens to our shoes and the stairs when we go downstairs.)

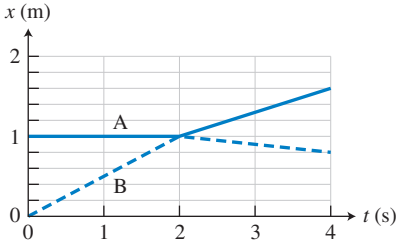


FIGURE P7.46

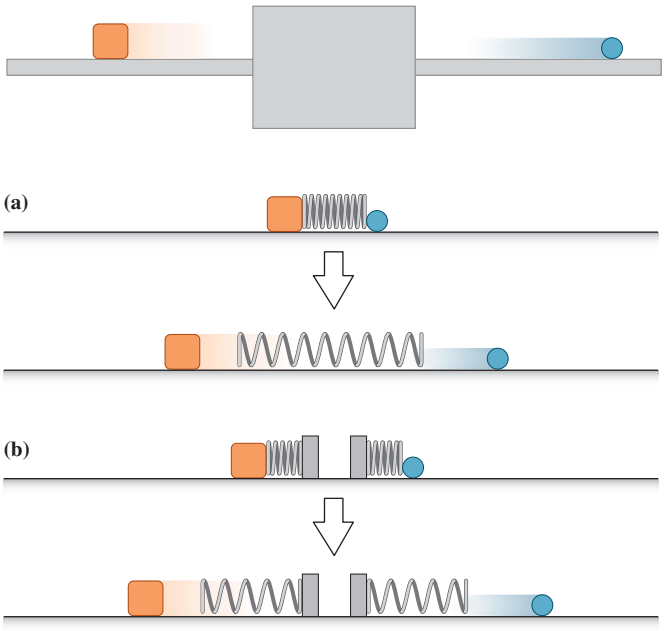
7.7 Collisions



47. A 4.0-kg block moving at 2.0 m/s west on a frictionless surface collides totally inelastically with a second 1.0-kg block traveling east at 3.0 m/s. (a) Determine the final velocity of the blocks. (b) Determine the kinetic energy of each block before and after the collision. (c) What happens to the difference in kinetic energies in this process?
48. * A 1060-kg car moving west at 16 m/s collides with and locks onto a 1830-kg stationary car. (a) Determine the velocity of the cars just after the collision. (b) After the collision, the road exerts a 1.2×10^4-N friction force on the car tires. How far do the cars skid before stopping? Specify the system and the initial and final states of the process.
49. * You fire an 80-g arrow so that it is moving at 80 m/s when it hits and embeds in a 10-kg block resting on ice. (a) What is the velocity of the block and arrow just after the collision? (b) How far will the block slide on the ice before stopping? A 7.2-N friction force opposes its motion. Specify the system and the initial and final states for (a) and (b).
50. * You fire a 50-g arrow that moves at an unknown speed. It hits and embeds in a 350-g block that slides on an air track. At the end, the block runs into and compresses a 4000-N/m spring 0.10 m. How fast was the arrow traveling? Indicate the assumptions that you made and discuss how they affect the result.
51. * To confirm the results of Problem 7.50, you try a new experiment. The 50-g arrow is launched in an identical manner so that it hits and embeds in a 3.50-kg block. The block hangs from strings. After the arrow joins the block, they swing up so that they are 0.50 m higher than the block's starting point. How fast was the arrow moving before it joined the block?
52. * Somebody tells you that **Figure P7.52** shows a displacement-versus-time graph of two carts on a linear track before and after a collision, when friction and air drag are negligible. The mass of cart A is 2.0 kg and mass of cart B is 1.0 kg. (a) Is the graph in agreement with the laws of physics? Explain. (b) If yes, is the collision elastic, inelastic, or totally inelastic? Explain. You will need a ruler to solve this problem.

FIGURE P7.52

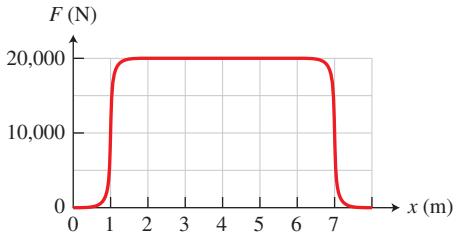
53. ** Some students are investigating an unknown device that is shooting objects in opposite directions, as shown in **Figure P7.53**. The objects can have different masses and are therefore ejected from the device with different speeds. The objects are always launched in pairs. The students propose two different explanations for the object-launching mechanism.

FIGURE P7.53

Mechanism 1: Two objects are touching opposite ends of a very light spring that is initially compressed always for the same amount (Figure P7.53a). When the spring is released, it pushes on the objects and makes them fly in opposite directions. The spring is not attached to anything.

Mechanism 2: Each object is touching its own light spring that is initially compressed always for the same amount. The springs are identical and are compressed by the same distance (Figure P7.53b). When the springs are released, they push on the objects and cause them to fly in opposite directions.

The students also measure the masses and speeds of the pairs of the objects that are launched together (see the table below). Can you reject one or both mechanisms using the data in the table? Are there any events in the table that are in agreement with both mechanisms? Explain.



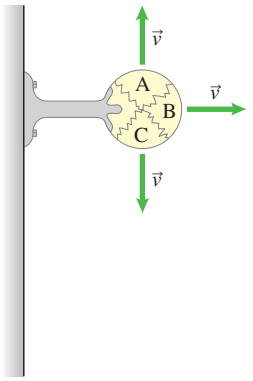
Event #	m_1 (g)	v_1 (m/s)	m_2 (g)	v_2 (m/s)
1	1.0	3.0	2.0	1.5
2	1.0	2.0	1.0	2.0
3	2.0	1.5	3.0	1.0
4	2.0	2.0	1.0	4.0
5	3.0	1.0	2.0	1.5

7.8 Power

54. A roofing shingle elevator is lifting a 10.0-kg package to the top of a building at constant speed. The angle between the elevator track and the horizontal is 75°. The power of the elevator is 700 W. What is the vertical component of the speed with which the package is moving up? Indicate any assumptions that you made.
55. (a) What is the power involved in lifting a 1.0-kg object 1.0 m in 1.0 s? (b) While lifting a 10-kg object 1.0 m in 0.50 s? (c) While lifting the 10-kg object 2.0 m in 1.0 s? (d) While lifting a 20-kg object 1.0 m in 1.0 s?
56. * A fire engine must lift 30 kg of water a vertical distance of 20 m each second. What is the amount of power needed for the water pump for this fire hose?

57. * BIO **Internal energy change while biking** You set your stationary bike on a high 80-N friction-like resistive force and cycle for 30 min at a speed of 8.0 m/s. Your body is 10% efficient at converting chemical energy in your body into mechanical work. (a) What is your internal chemical energy change? (b) How long must you bike to convert 3.0×10^5 J of chemical potential while staying at this speed? (This amount of energy equals the energy released by the body after eating three slices of bread.)
58. * **Climbing Mt. Mitchell** An 82-kg hiker climbs to the summit of Mount Mitchell in western North Carolina. During one 2.0-h period, the climber's vertical elevation increases 540 m. Determine (a) the change in gravitational potential energy of the climber-Earth system and (b) the power of the process needed to increase the gravitational energy.
59. * BIO EST **Sears stair climb** The fastest time for the Sears Tower (now Willis Tower) stair climb (103 flights, or 2232 steps) is about 13 min. (a) Estimate the mechanical power in watts for a top climber. Indicate any assumptions you made. (b) If the body is 20% efficient at converting chemical energy into mechanical energy, approximately how many joules and kilocalories of chemical energy does the body expend during the stair climb? Note: 1 food calorie = 1 kilocalorie = 4186 J.
60. * BIO EST **Exercising so you can eat ice cream** You curl a 5.5-kg (12 lb) dumbbell that is hanging straight down in your hand up to your shoulder. (a) Estimate the work that your hand does in lifting the dumbbell. (b) Estimate the average mechanical power of the lifting process. Indicate any assumptions used in making the estimate. (c) Assuming the efficiency described at the end of Problem 7.59, how many times would you have to lift the dumbbell in order to burn enough calories to use up the energy absorbed by eating a 300-food-calorie dish of ice cream? (Problem 7.59 provides the joule equivalent of a food calorie.) List the assumptions that you made.
61. ** BIO **Salmon move upstream** In the past, salmon would swim more than 1130 km (700 mi) to spawn at the headwaters of the Salmon River in central Idaho. The trip took about 22 days, and the fish consumed energy at a rate of 2.0 W for each kilogram of body mass. (a) What is the total energy used by a 3.0-kg salmon while making this 22-day trip? (b) About 80% of this energy is released by burning fat and the other 20% by burning protein. How many grams of fat are burned? One gram of fat releases 3.8×10^4 J of energy. (c) If the salmon is about 15% fat at the beginning of the trip, how many grams of fat does it have at the end of the trip?
62. * EST Estimate the maximum horsepower of the process of raising your body mass as fast as possible up a flight of 20 stair steps. Justify any numbers used in your estimate. The only energy change you should consider is the change in gravitational potential energy of the system you-Earth.
63. * A 1600-kg car smashes into a shed and stops. The force that the shed exerts on the car as a function of a position at the car's center is shown in **Figure P7.63**. How fast was the car traveling just before hitting the shed?

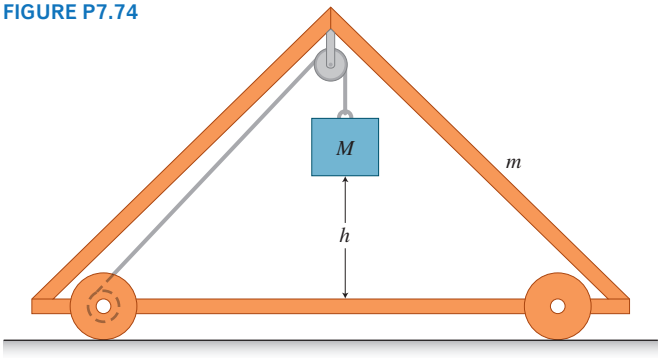
FIGURE P7.63



7.9 Improving our model of gravitational potential energy

64. At what distance from Earth is the gravitational potential energy of a spaceship-Earth system reduced to half the energy of the system before the launch?
65. * **Possible escape of different air molecule types** (a) Determine the ratio of escape speeds from Earth for a hydrogen molecule (H_2) and for an oxygen molecule (O_2). The mass of the oxygen is approximately 16 times that of the hydrogen. (b) In the atmosphere, the average random kinetic energy of hydrogen molecules and oxygen molecules is the same. Determine the ratio of the average speeds of the hydrogen and the oxygen molecules. (c) Based on these two results, give one reason why our atmosphere lacks hydrogen but retains oxygen.
66. Determine the escape speed for a rocket to leave Earth's Moon.
67. Determine the escape speed for a rocket to leave the solar system.
68. If the Sun were to become a black hole, how much would it increase the gravitational potential energy of the Sun-Earth system?
69. * A satellite moves in elliptical orbit around Earth, which is one of the foci of the elliptical orbit. (a) The satellite is moving faster when it is closer to Earth. Explain why. (b) If the satellite moves faster when it is closer to Earth, is the energy of the satellite-Earth system constant? Explain.
70. * Determine the maximum radius Earth's Moon would have to have in order for it to be a black hole.

General Problems



71. You throw a clay ball vertically upward. The ball hits the ceiling and sticks to it. Let the initial state be just after the ball leaves your hand and the final state just after the ball sticks to the ceiling. Choose a system and represent the process with a work-energy bar chart. Indicate any assumptions that you made.
72. * A spherical street lamp accidentally explodes. Three equal pieces A, B, and C fly off the lamp holder with equal speeds but in different directions, as shown in **Figure P7.72**. (a) Compare the speeds with which each piece hits the ground. (b) Compare qualitatively the times needed for each piece to reach the ground. Indicate any assumptions that you made.

FIGURE P7.72

73. Assume that in the previous problem each piece of the lamp has mass m. Develop expressions for the magnitude of (a) the total kinetic energy and (b) the total momentum of the three pieces together just after the explosion.
74. * EST A "gravity force car" is powered by the force exerted by Earth on an object of mass M. The object is tied to a rope that is turning the axle of the rear wheels, as shown in **Figure P7.74**. The mass of the car (excluding the hanging object) is m. As the car accelerates, the object descends a distance h. (a) Ignoring air resistance and friction in the pulley and wheels, derive an expression for the final speed of the car. (b) Based on your answer to part (a), what would you suggest to the designers of such a car if the goal is to achieve the greatest final speed? (c) Estimate the maximum final speed of a tabletop version of a gravity force car (think of reasonable values for the variables in the equation that you derived).[1]

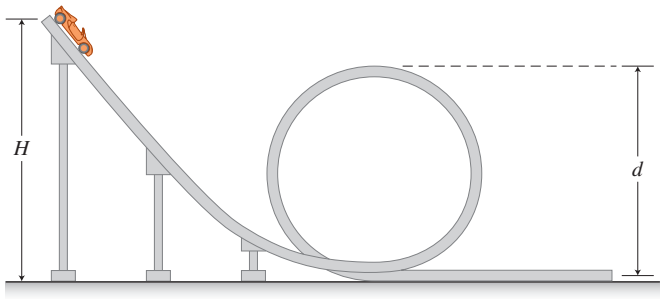


FIGURE P7.74

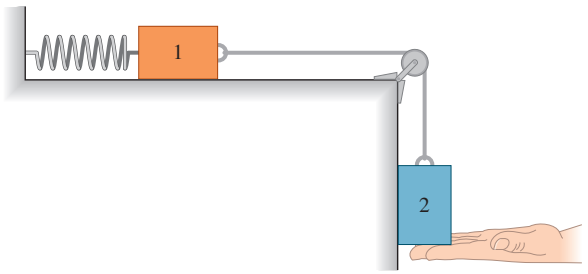
[1]This problem was inspired by Gordon Aubrecht, who sadly passed away in 2016.

75. * **Loop the loop** You are given a loop raceway for your Hot Wheels cars (as shown in Figure P7.75). While playing with the cars, you and your friends notice that you need to release the car from at least a height H of 1.30 diameters of the loop above the ground for the car not to fall off the track at the top of the circular loop. Two of your friends have different explanations for the observed pattern:

FIGURE P7.75

Jordan: If there were no friction forces exerted on the car, the minimum height H would be equal to the loop diameter d because the mechanical energy of the car-Earth system is constant in the process.



Leila: The minimum height H is larger than the loop diameter d even if the friction forces are negligible. The car's speed at the top of the loop should be large enough that the force exerted by Earth on the car alone keeps the car moving in a circle determined by the loop.

Analyze the problem and decide which of your friends is correct.

76. ** **Atwood machine** Two blocks of masses m_1 and m_2 hang at the ends of a string that passes over a very light pulley (see Figure Q7.3). Friction in the pulley can be ignored. The blocks are initially at rest at the same height (the initial state). After they are released, the heavier block m_2 moves through a distance d (the final state). Represent the process with work-energy bar charts choosing as a system (a) block 1 and Earth, (b) block 1, block 2, and Earth, and (c) block 1 and block 2. (d) Derive an expression for the final speed of the blocks in terms of m_1, m_2, and d, and evaluate the expression using unit analysis and extreme case analysis.

77. ** Two blocks of masses m_1 and m_2 are connected with a string that passes over a very light pulley (see Figure P7.77). Friction in the pulley can be ignored. Block 1 is resting on a rough table and block 2 is hanging over the edge. The coefficient of friction between the block 1 and the table is μ (assume static and kinetic friction have the same value). Block 1 is also connected to a spring with a constant k. In the initial state, the spring is relaxed as a person is holding block 2, but the string is still taut. When block 2 is released, it moves down for a distance d until it stops (the final state). (a) Explain why block 2 eventually stops moving. (b) Choose a system and represent the process with a work-energy bar chart. (c) Derive the expression for distance d in terms of m_1, m_2, μ, and k, and evaluate the expression using extreme case analysis and unit analysis.

FIGURE P7.77

78. ** BIO EST **Impact extinction** 65 million years ago over 50% of all species became extinct, ending the reign of dinosaurs and opening the way for mammals to become the dominant land vertebrates. A theory for this extinction, with considerable supporting evidence, is that a 10-km-wide 1.8×10^{15}-kg asteroid traveling at speed 11 km/s crashed into Earth. Use this information and any other information or assumptions of your choosing to (a) estimate the change in velocity of Earth due to the impact; (b) estimate the average force that Earth exerted on the asteroid while stopping it; and (c) estimate the internal energy produced by the collision (a bar chart for the process might help). By comparison, the atomic bombs dropped on Japan during World War II were each equivalent to 15,000 tons of TNT (1 ton of TNT releases 4.2×10^9 J of energy).

79. ** Newton's cradle is a toy that consists of several metal balls touching each other and suspended on strings (Figure P7.79). When you pull one ball to the side and let it strike the next ball, only one ball swings out on the other side. When you use two balls to hit the others, two balls swing out. Can you account for this effect using your knowledge about elastic collisions?

FIGURE P7.79

80. * Pose a problem involving work-energy ideas with real numbers. Then solve the problem choosing two different systems and discuss whether the answers were different.

81. ** **Six Flags roller coaster** A loop-the-loop on the Six Flags Shockwave roller coaster has a 10-m radius (Figure P7.81). The car is moving at 24 m/s at the bottom of the loop. Determine the force exerted by the seat of the car on an 80-kg rider when passing inverted at the top of the loop.

FIGURE P7.81

82. ** **Designing a ride** You are asked to help design a new type of loop-the-loop ride. Instead of rolling down a long hill to generate the speed to go around the loop, the 300-kg cart starts at rest (with two passengers) on a track at the same level as the bottom of the 10-m radius loop. The cart is pressed against a compressed spring that, when released, launches the cart along the track around the loop. Choose a spring of the appropriate spring constant to launch the cart so that the downward force exerted by the track on the cart as it passes the top of the loop is 0.2 times the force that Earth exerts on the cart. The spring is initially compressed 6.0 m.

Reading Passage Problems

BIO **Metabolic rate** Energy for our activities is provided by the chemical energy of the foods we eat. The absolute value of the rate of conversion of this chemical energy into other forms of energy ($\Delta E/\Delta t$) is called the metabolic rate. The metabolic rate depends on many factors—a person's weight, physical activity, the efficiency of bodily processes, and the fat-muscle ratio. Table 7.9 lists the metabolic rates of people under several different conditions and in several different units of measure: 1 kcal = 1000 calories = 4186 J. Dieticians call a kcal simply a Cal. A piece of bread provides about 70 kcal of metabolic energy.

In 1 hour of heavy exercise a 68-kg person metabolizes 600 kcal − 90 kcal = 510 kcal more energy than when at rest. Typically, reducing kilocalorie intake by 3500 kcal (either by burning it in exercise or not consuming it in the first place) results in a loss of 0.45 kg of body mass (the mass is lost through exhaling carbon dioxide—the product of metabolism).

TABLE 7.9 Energy usage rate during various activities

Type of activity	$\Delta E/\Delta t$ (watts)	$\Delta E/\Delta t$ (kcal/h)	$\Delta E/\Delta t$ (kcal/day)
45-kg person at rest	80	70	1600
68-kg person at rest	100	90	2100
90-kg person at rest	120	110	2600
68-kg person walking 3 mph	280	240	5800
68-kg person moderate exercise	470	400	10,000
68-kg person heavy exercise	700	600	14,000

83. Why is the metabolic rate different for different people?
(a) They have different masses.
(b) They have different body function efficiencies.
(c) They have different levels of physical activity.
(d) All of the above

84. A 50-kg mountain climber moves 30 m up a vertical slope. If the muscles in her body convert chemical energy into gravitational potential energy with an efficiency of no more than 5%, what is the chemical energy used to climb the slope?
(a) 7 kcal (b) 3000 J
(c) 70 kcal (d) 300,000 J

85. If 10% of a 50-kg rock climber's total energy expenditure goes into the gravitational energy change when climbing a 100-m vertical slope, what is the climber's average metabolic rate during the climb if it takes her 10 min to complete the climb?
(a) 8 W (b) 80 W (c) 500 W
(d) 700 W (e) 800 W

86. EST A 68-kg person wishes to lose 4.5 kg in 2 months. Estimate the time that this person should spend in moderate exercise each day to achieve this goal (without altering her food consumption).
(a) 0.4 h (b) 0.9 h (c) 1.4 h
(d) 1.9 h (e) 2.4 h

87. EST A 68-kg person walks at 5 km per hour for 1 hour a day for 1 year. Estimate the *extra* number of kilocalories of energy used because of the walking.
(a) 40,000 kcal (b) 47,000 kcal
(c) 88,000 kcal (d) 150,000 kcal

88. Suppose that a 90-kg person walks for 1 hour each day for a year, expending 50,000 extra kilocalories of metabolic energy (in addition to his normal resting metabolic energy use). What approximately is the person's mass at the end of the year, assuming his food consumption does not change?
(a) 57 kg (b) 61 kg (c) 64 kg
(d) 66 kg (e) 67 kg

BIO **Kangaroo hopping** Hopping is an efficient method of locomotion for the kangaroo (see **Figure 7.18**). When the kangaroo is in the air, the Earth-kangaroo system has a combination of gravitational potential energy and kinetic energy. When the kangaroo lands, its Achilles tendons and the attached muscles stretch—a form of elastic potential energy. This elastic potential energy is used along with additional muscle tension to launch the kangaroo off the ground for the next hop. In the red kangaroo, more than 50% of the total energy used during each hop is recovered elastic potential energy. This is so efficient that the kangaroo's metabolic rate actually decreases slightly as its hopping speed increases from 8 km/h to 25 km/h.

The horizontal and vertical force components exerted by a firm surface on a kangaroo's feet while it hops are shown in **Figure 7.19a**. The vertical force $N_{\text{S on K}\,y}$ (Figure 7.19b) varies: when the kangaroo is not touching the surface S, the force is zero; when it is pushing off, the force is about three times the gravitational force that Earth exerts on the kangaroo. The surface exerts a backward horizontal force ($F_{\text{S on K}\,x}$) on the kangaroo's foot while it lands and a forward horizontal force as it pushes off for the next hop (Figure 7.19c), similar to what happens to a human foot when landing in front of the body and when pushing off for another step when behind the body.

89. Why is hopping an energy-efficient mode of transportation for a kangaroo?
(a) There is less resistance since there is less contact with the ground.
(b) The elastic energy stored in muscles and tendons when landing is returned to help with the next hop.
(c) The kangaroo has long feet that cushion the landing.
(d) The kangaroo's long feet help launch the kangaroo.

90. Why does the horizontal force exerted by the ground on the kangaroo change direction as the kangaroo lands and then hops forward?
(a) The backward force when it lands prevents it from slipping, and the forward force when taking off helps propel it forward.
(b) One horizontal force is needed to help stop the kangaroo's fall and the other to help launch its upward vertical hop.
(c) Both forces oppose the kangaroo's motion, but one looks like it is forward because the kangaroo is moving fast.
(d) The kangaroo is not an inertial reference frame, and the forward force is not real.
(e) All of the above

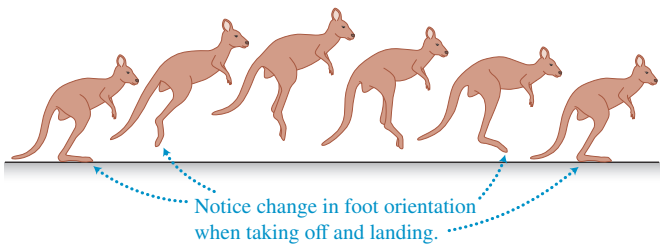
91. Which answer below is closest to the vertical impulse that the ground exerts on the kangaroo while it takes off?
(a) 0 (b) $+50\ \text{N}\cdot\text{s}$ (c) $+150\ \text{N}\cdot\text{s}$
(d) $-50\ \text{N}\cdot\text{s}$ (e) $-150\ \text{N}\cdot\text{s}$

92. Which answer below is closest to the vertical impulse due to the gravitational force exerted on the kangaroo by Earth during the short time interval while it takes off?
(a) 0 (b) $+50\ \text{N}\cdot\text{s}$ (c) $+150\ \text{N}\cdot\text{s}$
(d) $-50\ \text{N}\cdot\text{s}$ (e) $-150\ \text{N}\cdot\text{s}$

93. Suppose the net vertical impulse on the 50-kg kangaroo due to all external forces was $+100\ \text{N}\cdot\text{s}$. Which answer below is closest to its vertical component of velocity when it leaves the ground? Assume that the kangaroo is initially at rest.
(a) $+2.0\ \text{m/s}$ (b) $+3.0\ \text{m/s}$ (c) $+4.0\ \text{m/s}$
(d) $+8.0\ \text{m/s}$ (e) $+10\ \text{m/s}$

94. Which answer below is closest to the vertical height above the ground that the kangaroo reaches if it leaves the ground traveling with a vertical component of velocity of 2.5 m/s?
(a) 0.2 m (b) 0.3 m (c) 0.4 m
(d) 0.6 m (e) 0.8 m

FIGURE 7.18 A kangaroo hopping.



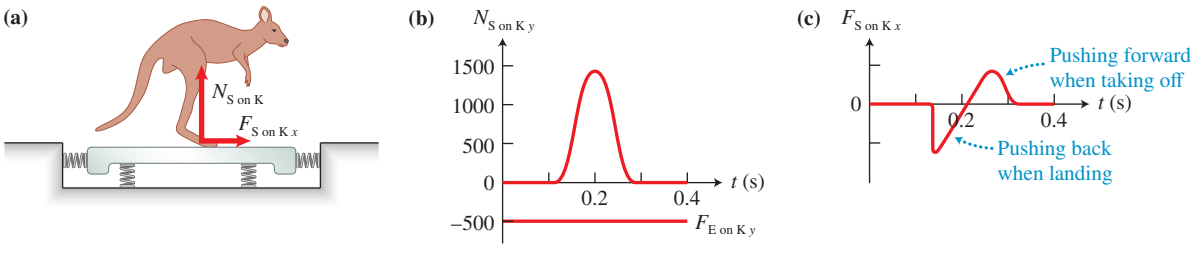


FIGURE 7.19 The kangaroo stores elastic potential energy in its muscle and tendon when landing and uses some of that energy to make the next hop.

8

Extended Bodies at Rest

Back pain is a major health problem. In 2010 in the United States, the medical costs related to back pain were around 80 billion dollars a year, about the same as the yearly cost of treating cancer. Back pain often results from incorrect lifting, which compresses the disks in the lower back, causing nerves to be pinched. Understanding the physics principles underlying lifting can help us develop techniques that minimize this compression and prevent injuries.

- **Why is it best to lift heavy objects with your knees bent and the object near your body?**
- **Why are doorknobs located on the side of the door opposite the hinges?**
- **Why is the force that your biceps muscle exerts on your forearm when lifting a barbell about seven times stronger than the force that Earth exerts on it?**

SO FAR IN THIS BOOK we have primarily been modeling moving objects as point-like with no internal structure. This method is appropriate when the shapes of objects do not affect the consequences of their interactions with each other—for example, an elevator moving up a shaft or an apple falling into a pile of leaves. However, objects in general and the human body in particular are extraordinarily complex, with many internal parts that rotate and move relative to one another. To study the body and other complex structures, we need to develop a new way of modeling objects and analyzing their interactions.

BE SURE YOU KNOW HOW TO:

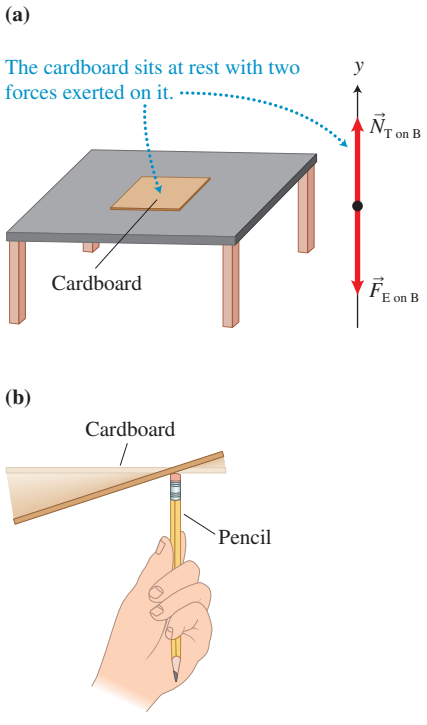
- Define the point-like model for an object (Section 2.2).
- Draw a force diagram for a system (Section 3.1).
- Use the component form of Newton's second law (Section 4.2).

8.1 Extended and rigid bodies

In earlier chapters we focused on situations in which real objects that have nonzero dimensions could be reasonably modeled as point-like. Such modeling is possible when an object moves as a whole from one location to another, without turning. Such motion is called **translational motion**.

In this chapter we will be analyzing objects whose size and shape matter. We will start with the simplest case—objects at rest. (In Chapter 9 we will investigate their motion.) We'd like, for example, to understand how the contemporary dancers in **Figure 8.1** manage to maintain their unusual balance. Where should each force be exerted and how large should their magnitudes be in order for the dancers to remain stable? To answer these questions, we need a new model for extended objects and a new method for analyzing the forces that objects exert on each other. Our first task is to develop this new model for objects.

FIGURE 8.1 The point-like model of an object is not useful when we try to analyze the balance of these dancers.

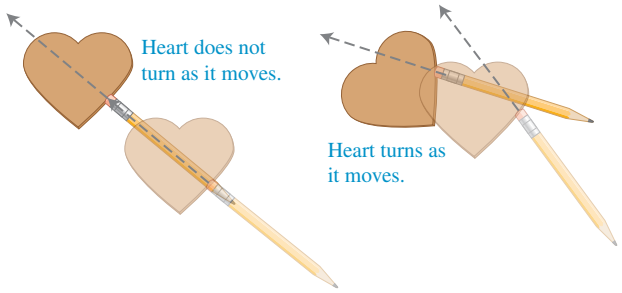


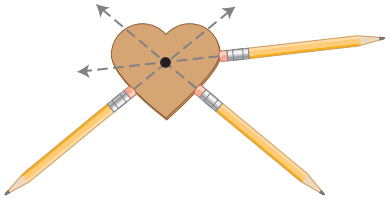
Rigid bodies

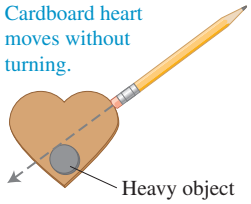
Notice that at the instant shown in the photo the various parts of the dancers' bodies are not moving with respect to each other. They are acting as a single rigid object. This observation motivates a new model for an extended object, in which the size of the object is not zero (it is not a point-like object), but parts of the object do not move with respect to each other. In physics, this model is called a **rigid body**.

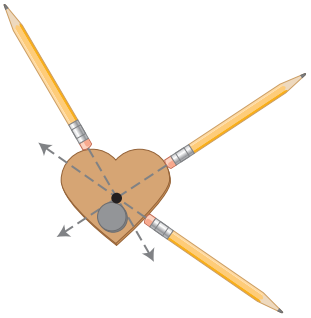
Rigid body A rigid body is a model of a real extended object. When we model an extended object as a rigid body, we assume that the object has a nonzero size but the distances between all parts of the object remain the same (the size and shape of the object do not change).

FIGURE 8.2 The cardboard is stable in (a) but not in (b). The place where the supporting force is exerted on the board matters.









Many bones in your body can be reasonably modeled as rigid bodies, as can many everyday objects—buildings, bridges, streetlights, and utility poles. However, many objects cannot be modeled as rigid bodies. Objects that cannot be modeled as rigid bodies include ones that contain liquid or moving interior parts, such as water balloons or boxes of loose candy. In this chapter we will investigate what conditions are necessary for a rigid body to remain at rest.

Center of mass

Let's start with some simple experiments. Place a piece of thin, flat cardboard on a very smooth table. If we consider the cardboard to be a point-like object, on a force diagram the upward normal force that the table exerts on the cardboard will balance the downward gravitational force that Earth exerts on the cardboard (**Figure 8.2a**)—the cardboard will not accelerate. Now, place the cardboard on a very small surface—like the eraser of a pencil. The cardboard tilts and falls off (Figure 8.2b). Does this result mean that the eraser cannot exert the same upward force on the cardboard that the table did, or is there some other explanation? The model of the point-like object cannot explain the tilting, since point-like objects do not tilt. Perhaps we need to model the cardboard as a rigid body. Before we do this, let us learn a little more about rigid bodies in Observational Experiment **Table 8.1**.

OBSERVATIONAL EXPERIMENT TABLE 8.1 Pushing a board so that it moves without turning

VIDEO OET 8.1

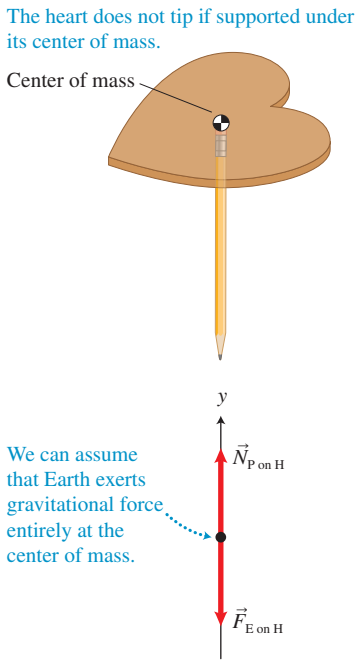
Observational experiment	Analysis
Experiment 1. We push with a pencil eraser on the edge of a heart-shaped piece of flat cardboard at different locations such that for each push the cardboard moves on a smooth surface without turning. We also push against the cardboard at points where it turns as it moves. 	We draw lines across the top of the cardboard from the places and in the directions that the cardboard did not turn as it moved. The lines along which the forces are exerted all cross at one point. 
Experiment 2. We now place a heavy object on the cardboard and repeat the experiment, each time pushing at different locations along the edge, trying to find the direction of pushing so that for each push the cardboard moves without turning. 	The lines along which the forces are exerted all cross at one point. This point is located somewhere between the point in experiment 1 and the position of the added object in experiment 2. 

Pattern

1. In both experiments, all of the lines along which we had to push to move the cardboard without it turning pass through a common point on the cardboard.
2. Pushing at the same locations in other directions causes the cardboard to turn as it moves.

The analysis we did in Table 8.1 indicates that a rigid body possesses a special point. If a force exerted on that object points directly toward or away from that point, the object will not turn. We call this point the object's **center of mass**. It is found experimentally that the center of mass is not necessarily located at the geometrical center of the object, but depends on the distribution of mass in the object.

Center of mass (qualitative definition) The center of mass of an object is a point where a force exerted on the object pointing directly toward or away from that point will not cause the object to turn. The location of this point depends on the mass distribution of the object.



TIP Although the location of the center of mass depends on the mass distribution of the object, the mass of the object is not necessarily evenly distributed around the center of mass. We will learn more about the properties of the center of mass; we just want to caution you against taking the name of this point literally.

Where is the gravitational force exerted on a rigid body?

At the beginning of the chapter we found that we could not balance cardboard on the eraser of a pencil. Why did the cardboard fall off? Imagine drawing the forces exerted on the cardboard. The cardboard interacts with two objects: the eraser and Earth. The eraser exerts an upward normal force on the cardboard at the point where it touches it. Earth exerts a downward gravitational force on every part of the cardboard. Is it possible to simplify the situation and to find one location at which we can assume that the entire gravitational force is exerted on the cardboard?

Let us go back to the heart-shaped cardboard from Experiment 1 in Table 8.1. If we place the eraser exactly under the cardboard's center of mass, the cardboard does not tip over and fall (**Figure 8.3**). If the cardboard does not tip, it means that all forces exerted on it, including the force exerted by Earth and the force exerted by the eraser, pass through the center of mass. The normal force exerted by the eraser passes through the place where it contacts the cardboard—below the center of mass (indicated on the figure with a checked circle).

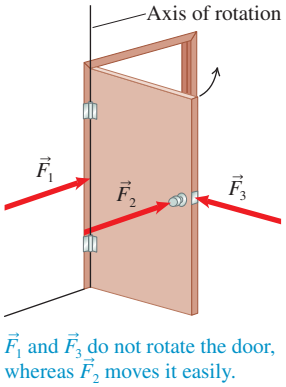
FIGURE 8.3 Balancing cardboard.

Earth exerts a small force on each small part of the board, but we can assume that the total force is exerted exactly at the center of mass. That is why sometimes the object's center of mass is called the object's **center of gravity**. Note that the center of gravity is located at the same spot as the center of mass only when the object is so small that we can neglect the change of g throughout the object. For example, if you think of a large spaceship close to Earth, the value of g at the points closer to Earth is larger than at the points that are farther.

When we model something as a point-like object, we model it as if all of the object's mass is located at its center of mass. Likewise, we can apply what we know about translational motion for point-like objects to rigid bodies, as long as we apply the rules to their centers of mass. **When multiple forces are exerted on a rigid body, the center of mass of the rigid body accelerates translationally according to Newton's second law $\vec{a} = \Sigma\vec{F}/m$.**

REVIEW QUESTION 8.1 You have an oval framed painting. How do you determine where you should insert a single nail into the frame so that the painting is correctly oriented in both the vertical and horizontal directions?

8.2 Torque: a new physical quantity



We learned in the previous section that the turning effect of an individual force depends on where and in which direction the force is exerted on an object. The translational acceleration of the object's center of mass is still determined by Newton's second law, independently of where the force is exerted. In this section we will learn about the turning ability of a force that an object exerts on a rigid body.

Axis of rotation

When objects turn around an axis, physicists say that they undergo **rotational motion**. The axis may be a fixed physical axis, such as the hinge of a door, or it may not, as in the case of a spinning top. In this chapter we will focus on the conditions under which objects that could potentially rotate do not do so.

Consider a door. When you push on the doorknob perpendicular to the door's surface ($\vec{F}_2$ in **Figure 8.4**), it rotates easily about the door hinges. We call the imaginary line passing through the hinges the **axis of rotation**. You know from experience that pushing a door at or near the axis of rotation ($\vec{F}_1$ in Figure 8.4) is not as effective as

FIGURE 8.4 Different forces have different effects in turning a door about its axis of rotation.

pushing the doorknob. You also know that the harder you push near the knob, the more rapidly the door starts moving. Lastly, pushing on the outside edge of the door toward the axis of rotation ($\vec{F}_3$ in Figure 8.4) does not move the door at all.

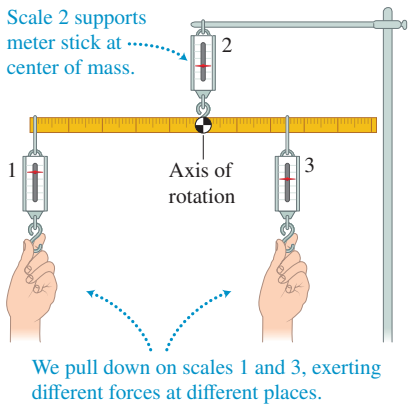
These observations suggest that three factors affect the turning ability of a force: (1) the place where the force is exerted, (2) the magnitude of the force, and (3) the direction in which the force is exerted. Next, let's construct a quantitative expression for this turning ability.

The role of position on the turning ability of a force

In order to quantify the turning ability of a force, we take a 0.10-kg meter stick and suspend it at its center of mass from spring scale 2 (**Figure 8.5**); $\vec{F}_2$ is the force exerted on the meter stick by scale 2 at the point of suspension. Spring scale 1 pulls perpendicularly on the stick, exerting a downward force $\vec{F}_1$ at different locations on the left side, and scale 3 exerts a downward perpendicular force $\vec{F}_3$ at different locations on the right side. Earth exerts a 1.0-N force $\vec{F}_{\text{E on M}}$ on the stick's center of mass, which is the point of suspension.

When either scale 1 or scale 3 pulls alone on the stick, the stick rotates (when scale 1 pulls on the stick, it rotates counterclockwise; when 3 pulls, it rotates clockwise). If we pull equally on scales 1 and 3 ($\vec{F}_1 = \vec{F}_3$) but the scales are located at different distances from the axis of rotation, the stick rotates (**Figure 8.6a**). We can use trial and error to find the combinations where the scales can be placed and pulled such that the stick does not rotate. For example, if scale 1 is twice as far from the axis of rotation and pulls half as hard as scale 3, the stick remains in equilibrium (Figure 8.6b). Similarly, if scale 1 is three times farther from the axis of rotation and exerts one-third of the force compared to scale 3, the stick remains in equilibrium (Figure 8.6c). When the stick does not rotate and does not move translationally, it is in a state of **static equilibrium**.

FIGURE 8.5 An experiment to determine a condition necessary for multiple forces to keep a meter stick in a horizontal position.



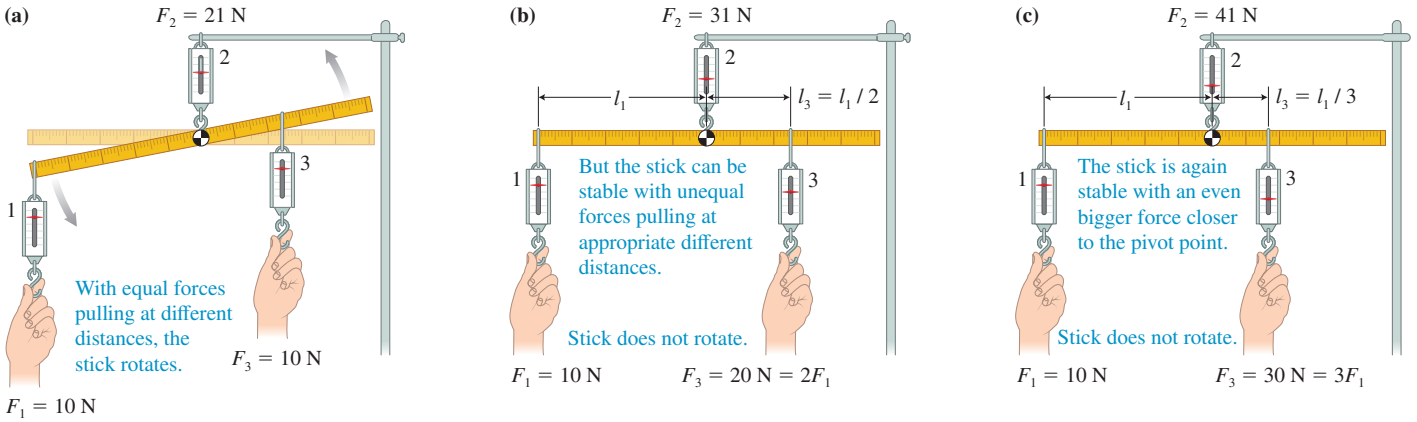


FIGURE 8.6 (a) The meter stick does not balance even though equal downward forces are exerted on each side. (b) and (c) A greater force on one side nearer the pivot point balances a smaller force on the other side farther from the pivot point.

Static equilibrium An object is said to be in static equilibrium when it *remains* at rest (does not undergo either translational or rotational motion) with respect to a particular observer in an inertial reference frame.

If we explore more situations in which the stick is not rotating, we find that when we have two springs pulling perpendicular to the stick, the stick remains in static equilibrium when the product of the magnitude of the force exerted by the scale on the

stick (F_1 or F_3 in our experiment) and the distance between where the force is exerted and the axis of rotation (l_1 or l_3 in our experiment) is the same for both forces:

$$F_1 l_1 = F_3 l_3$$

In other words, the turning ability of the force on the left cancels the turning ability of the force on the right, and the object is in static equilibrium.

The role of magnitude on the turning ability of a force

In addition, we notice that independently of whether the stick rotated or not, the reading of scale 2, F_2, supporting the stick always equals the sum of the readings of scales 1 and 3, $F_1 + F_3$, plus the magnitude of the force exerted by Earth on the stick $F_{\text{E on S}}$. In other words, in all cases the sum of the forces exerted on the stick was zero ($\Sigma F_y = 0$). This finding is consistent with what we know from Newton's laws—an object does not accelerate translationally if the sum of the forces exerted on it is zero. If it is originally at rest and does not accelerate translationally, then it remains at rest.

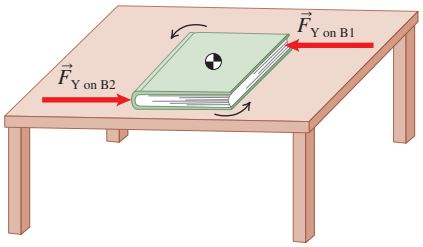
However, as we have seen from the experiment with the cardboard on the eraser, this sum-of-forces-equals-zero rule does not guarantee the rotational stability of rigid bodies (see Figure 8.2). Even when the sum of the forces exerted on the cardboard was zero, it could still start turning.

Another simple experiment helps illustrate this idea. Take a book with a glossy cover, place it on a smooth table (to minimize friction), and push it, exerting the same magnitude, oppositely directed force on each of two corners (as shown in **Figure 8.7a**). The force diagram in Figure 8.7b shows that the net force exerted on the book is zero—there is no translational acceleration. However, the book starts turning. The forces exerted by Earth and the table on the book pass through the book's center of mass; thus they do not cause turning. But the forces that you exert on the corners of the book do cause it to turn. Notice that these forces are of the same magnitude and are exerted at the same distance from the center of mass. You can imagine that there is an invisible axis of rotation passing through the center of mass perpendicular to the desk's surface. You would think that the turning effect caused by each force around this imaginary axis is the same; thus the two turning effects should cancel, as they did for scales 1 and 3 in the experiment described earlier. However, this does not happen. The fact that the book turns tells us that not only are the magnitude and placement of the force on the object important to describe the turning ability of the force, but the direction in which this force causes turning (for example, clockwise or counterclockwise around an axis of rotation) is also important.

By convention, physicists call counterclockwise turning about an axis of rotation positive and clockwise turning negative. So far, this is what we know about the new quantity that characterizes the turning ability of a force:

(a) It is equal to the product of the magnitude of the force and the distance the force is exerted from the axis of rotation.

(b) It is positive when the force tends to turn the object counterclockwise and negative when the force tends to turn the object clockwise.



(c) When one force tends to rotate an object counterclockwise and the other force tends to rotate an object clockwise, their effects cancel if $(F_{\text{counterclockwise}} l_1) + (-F_{\text{clockwise}} l_2) = 0$. In this case the object does not rotate.

Let's apply what we have devised so far to check whether this new quantity is useful for explaining other situations. Here is another simple experiment that you can do at home. Place a full milk carton or something of similar mass into a grocery bag. The bag with the milk carton by itself is not too heavy and you can easily lift it with one hand. Now hang the grocery bag from the end of a broomstick (**Figure 8.8a**). Try to support it by holding only the handle end of the broomstick with your hands close together. It is very difficult. Why?

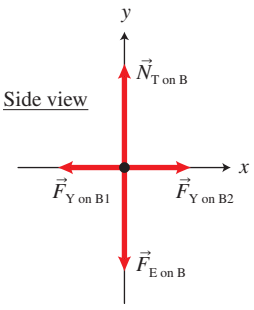


FIGURE 8.7 The turning effect of a force must depend on more than F and l.

(a)

The equal and opposite forces that you exert on the book at its corners cause the book to rotate.

(b)

The broomstick, the object of interest, can turn around an axis through the hand that is closest to you. The bag exerts a force on the broomstick far from this axis of rotation. This means that l_{Bag}, a quantity that we must find in order to determine the turning ability of the force exerted by the bag on the broomstick, is very large (Figure 8.8b). Your other hand, which is very close to the axis of rotation (distance l_{Hand}), must balance the effect of the bag. But since l_{Hand} is so small, the force your hand exerts must be very large. The outcome of this experiment agrees with what we learned so far about the turning ability of a force.

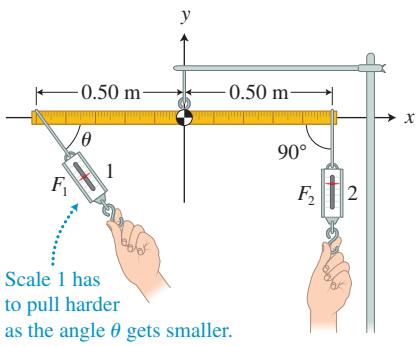
Holding the broomstick perpendicular to your body is quite difficult. However, if you hold the broomstick at an angle above the horizontal (Figure 8.8c), you find that the bag becomes easier to support. Why? Perhaps this has to do with the direction the force is exerted relative to the broomstick (see Figure 8.8d).

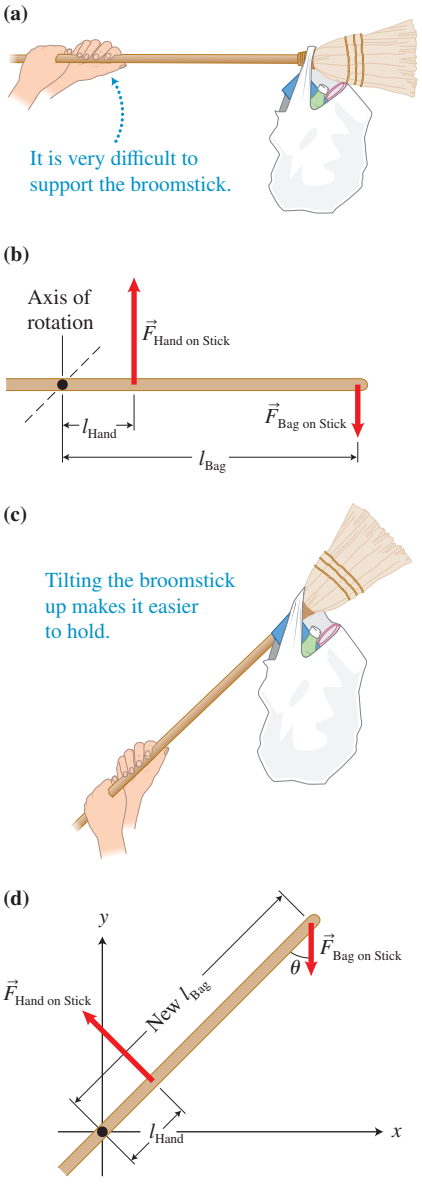
The role of angle on the turning ability of a force

Our current mathematical model of the physical quantity that characterizes the turning ability of the force ($\pm Fl$) takes into account the direction in which an exerted force can potentially rotate an object (clockwise or counterclockwise) but does not take into account the actual direction of the force. However, our experiment with the broomstick indicates that the angle at which we exert a force relative to the object affects the turning ability of the force. We know from experience that pushing on a door on its outside edge directly toward the hinges does not cause it to rotate. The direction of the push must matter. How can we improve our model for the physical quantity to take the direction of the force into account?

To investigate this question we can change our experiment with the meter stick slightly by making scale 1 pull on the stick at an angle other than 90° (**Figure 8.9**). Scale 2, on the far right end of the meter stick, 0.50 m from the suspension point, will exert a constant force of 10.0 N downward at a 90° angle. Scale 1 on the far left end of the stick will pull at different angles θ so that the meter stick remains horizontal. The results are shown in **Table 8.2**. In all cases the stick is horizontal—therefore, the turning ability of the force on the right is balanced by the turning ability of the force on the left.

FIGURE 8.9 An experiment to determine the angle dependence of the turning ability caused by a force.





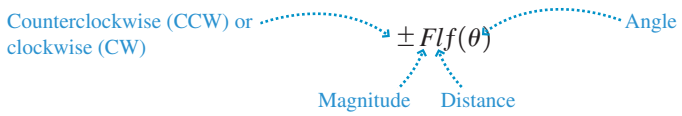


TABLE 8.2 Magnitude, location, and direction of force and its turning ability

Magnitude of $\vec{F}_1$	Distance to the axis of rotation	Angle θ between $\vec{F}_1$ and the stick	Turning ability produced by $\vec{F}_2$
10.0 N	0.50 m	90°	$-(10.0\ \text{N})(0.50\ \text{m}) = -5.0\ \text{N}\cdot\text{m}$
12.6 N	0.50 m	53°	$-(10.0\ \text{N})(0.50\ \text{m}) = -5.0\ \text{N}\cdot\text{m}$
14.2 N	0.50 m	45°	$-(10.0\ \text{N})(0.50\ \text{m}) = -5.0\ \text{N}\cdot\text{m}$
20.0 N	0.50 m	30°	$-(10.0\ \text{N})(0.50\ \text{m}) = -5.0\ \text{N}\cdot\text{m}$

FIGURE 8.8 Holding a bag at the end of a stick is more difficult when the stick is horizontal than when the stick is tilted up.

Using the data in the table, we see the effects of the magnitude and the angle of force $\vec{F}_1$ on its turning ability: the smaller the angle between the direction of the force and the stick, the larger the magnitude of the force that is necessary to produce the same turning ability. Thus we find that there are four factors that affect the turning ability of a force: (1) the direction (counterclockwise or clockwise) that the force can potentially rotate the object, (2) the magnitude of the force F, (3) the distance l of the point of application of the force from the axis of rotation, and (4) the angle θ that the force makes relative to a line from the axis of rotation to the point of application of the force. If we combine these four factors, the physical quantity characterizing the turning ability of a force takes a form such as

where $f(\theta)$ is some function of the angle θ.

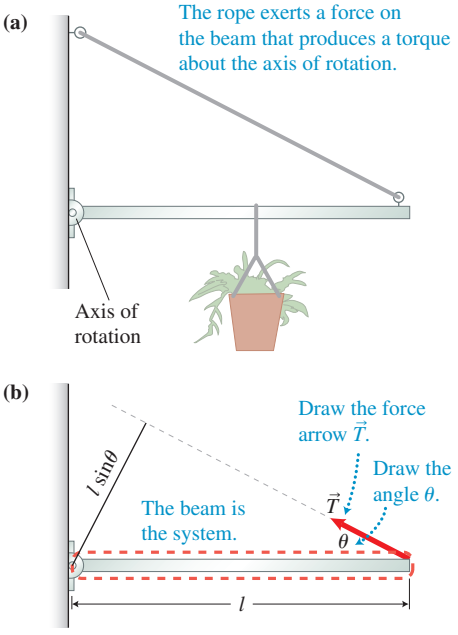
Consider the last row of Table 8.2. The force exerted by scale 1 is 0.50 m from the axis of rotation ($l = 0.50$ m), and the scale exerts a 20-N force F_1 on the stick at a 30° angle relative to the stick. This force produces the counterclockwise $+5.0\ \text{N}\cdot\text{m}$ effect needed to balance the $-5.0\ \text{N}\cdot\text{m}$ clockwise effect of scale 2. What value would $f(\theta)$ have to be to get this rotational effect?

$$+5.0\ \text{N}\cdot\text{m} = (20.0\ \text{N})(0.5\ \text{m})\ f(30^\circ)$$

or $f(30^\circ)$ must be 0.50. Recall that $\sin 30^\circ = 0.50$. Maybe the function $f(\theta)$ is the sine function, that is, $\tau = Fl \sin\theta$. Is this consistent with the other rows in Table 8.2?

$$+(10.0\ \text{N})(0.5\ \text{m})(\sin 90^\circ) = +5.0\ \text{N}\cdot\text{m}\ (1.00) = +5.0\ \text{N}\cdot\text{m}$$
$$+(12.6\ \text{N})(0.5\ \text{m})(\sin 53^\circ) = +6.3\ \text{N}\cdot\text{m}\ (0.80) = +5.0\ \text{N}\cdot\text{m}$$
$$+(14.2\ \text{N})(0.5\ \text{m})(\sin 45^\circ) = +7.1\ \text{N}\cdot\text{m}\ (0.71) = +5.0\ \text{N}\cdot\text{m}$$

This expression ($\tau = Fl \sin\theta$) is the mathematical definition of the new physical quantity that characterizes the ability of a force to turn (rotate) a rigid body. This physical quantity is called a **torque**. The symbol for torque is τ, the Greek letter tau.



Torque τ produced by a force The torque produced by a force exerted on a rigid body about a chosen axis of rotation is

$$\tau = \pm Fl \sin\theta \qquad (8.1)$$

where F is the magnitude of the force, l is the magnitude of the distance between the point where the force is exerted on the object and the axis of rotation, and θ is the angle that the force makes relative to a line connecting the axis of rotation to the point where the force is exerted (see **Figure 8.10**).

Figure 8.10 illustrates the method for calculating the turning ability (torque) due to a particular force. In this case, we are calculating the torque due to the force that the slanted rope exerts on the end of a beam that supports a load hanging from the beam. The torque is positive if the force has a counterclockwise turning ability about the axis of rotation, and negative if the force has a clockwise turning ability. The SI unit for torque is newton · meter, $\text{N}\cdot\text{m}$ (the British system unit is $\text{lb}\cdot\text{ft}$). Note that the expression $l \sin\theta$ gives us the shortest distance from the axis of rotation to the line along which the force producing the torque is exerted.

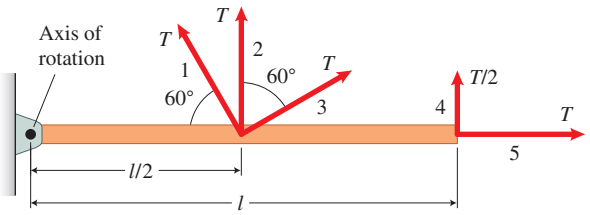


FIGURE 8.10 A method to determine the torque (turning ability) produced by a force.

TIP Notice that the units of torque ($\text{N}\cdot\text{m}$) are the same as the units of energy ($\text{N}\cdot\text{m} = \text{J}$). Torque and energy are very different quantities. We will always refer to the unit of torque as newton · meter ($\text{N}\cdot\text{m}$) and the unit of energy as joule (J).

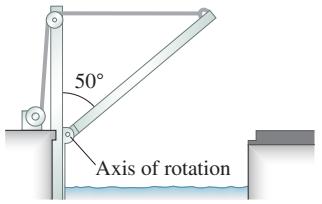
QUANTITATIVE EXERCISE 8.1 Rank the magnitudes of the torques

Suppose that five strings pull one at a time on a horizontal beam that can pivot about a pin through its left end, which is the axis of rotation. The magnitudes of the tension forces exerted by the strings on the beam are either T or $T/2$. Rank the magnitudes of the torques that the strings exert on the beam, listing the largest magnitude torque first and the smallest magnitude torque last. Indicate if any torques have equal magnitudes. Try to answer the question before looking at the answer below.

Represent mathematically A mathematical expression for the torque produced by each force is shown below. To understand why each torque is positive, imagine in what direction each string would turn the beam about the axis of rotation if that were the only force exerted on it. You will see that each string tends to turn the beam counterclockwise (except string 5).

Torque due to string 1: $\tau_1 = +T(l/2)\sin 60° = +0.43\ Tl$

Torque due to string 2: $\tau_2 = +T(l/2)\sin 90° = +0.50\ Tl$



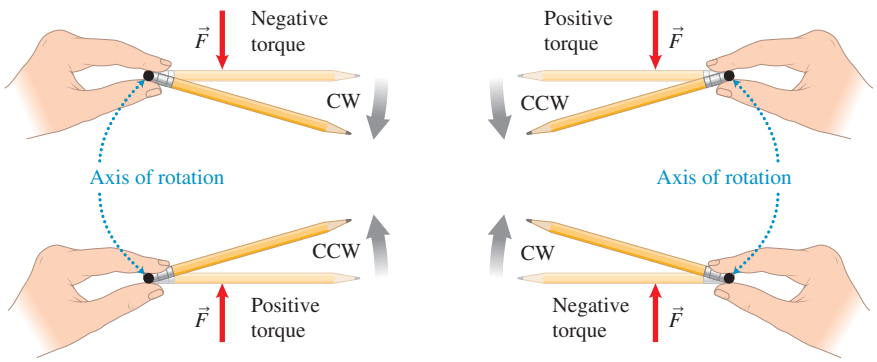
Torque due to string 3: $\tau_3 = +T(l/2)\sin 150° = +0.25\ Tl$

Torque due to string 4: $\tau_4 = +(T/2)l \sin 90° = +0.50\ Tl$

Torque due to string 5: $\tau_5 = +Tl \sin 0° = 0$

Solve and evaluate Notice that the angle used for the torque for the force exerted by rope 3 was 150° and not 60°—the force makes a 150° angle relative to a line from the pivot point to the place where the string exerts the force on the beam. String 5 exerts a force parallel to the line from the pivot point to the place where it is exerted on the beam; as a result, torque 5 is zero. The rank order of the torques is $\tau_2 = \tau_4 > \tau_1 > \tau_3 > \tau_5$.

Try it yourself Determine the torque caused by the cable pulling horizontally on the inclined drawbridge shown below. The force that the cable exerts on the bridge is 5000 N, the bridge length is 8.0 m, and the bridge makes an angle of 50° relative to the vertical support for the cable system.



Answer $\tau = +(5000\ \text{N})(8.0\ \text{m})\sin 40° = +26{,}000\ \text{N}\cdot\text{m}$. Note that we did not use 50° in our calculation. Why?

To decide the sign of the torque that a particular force exerts on a rigid body about a particular axis, pretend that a pencil is the rigid body. Hold it with two fingers at a place that represents the axis of rotation (**Figure 8.11**) and exert a force on the pencil representing the force whose torque sign you wish to determine. Does that force cause the pencil to turn counterclockwise (a + torque) or clockwise (a − torque) about the axis of rotation?

In this chapter we treat torque as a scalar quantity that can be positive or negative. The sign of the torque indicates the specific direction of rotation (compare this to work, the sign of which means adding or subtracting). The directional meaning of the sign hints that torque has a vector nature. You will learn more about the vector nature of torque in Chapter 9.

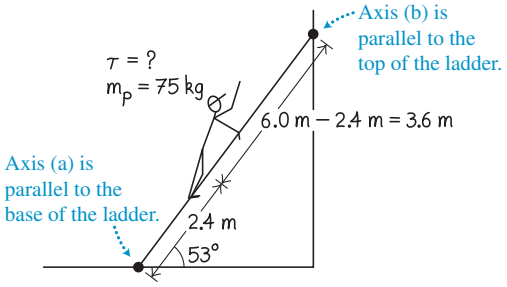


FIGURE 8.11 A method to determine the sign of a torque.

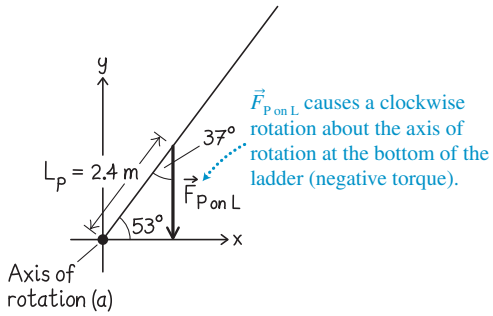


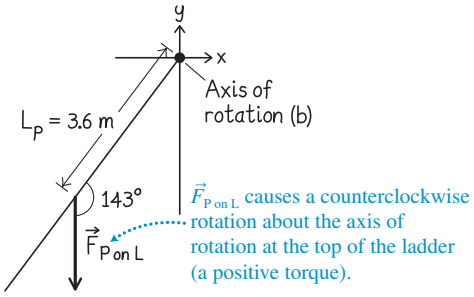
EXAMPLE 8.2 A painter on a ladder

A 75-kg painter stands on a 6.0-m-long 20-kg ladder tilted at 53° relative to the ground. He stands with his feet 2.4 m up the ladder. Determine the torque produced by the force exerted by the painter on the ladder for two choices of axis of rotation: (a) an axis parallel to the base of the ladder where it touches the ground and (b) an axis parallel to the top ends of the ladder where it touches the wall of the house.

Sketch and translate A sketch of the situation with the known information is shown below. The ladder is our system.

Simplify and diagram Four objects interact with the ladder: Earth, the painter's feet, the wall, and the ground. Our interest in this problem is only in the torque that the painter's feet exert on the ladder. Thus, we diagram for the ladder and the downward force $\vec{F}_{\text{P on L}}$ that the painter's feet exert on the ladder. The diagrams are for the two different axes of rotation.

Represent mathematically We use Eq. (8.1) for the torque caused by the force that the painter's feet exert on the ladder.



Solve and evaluate (a) For the first calculation, we choose the axis of rotation at the place where the feet of the ladder touch the ground. The torque produced by the force exerted by the painter's feet on the ladder is

$$\tau = -F_{\text{P on L}} l \sin\theta = -(m_p g) l \sin\theta$$
$$= -(75\ \text{kg})(9.8\ \text{N/kg})(2.4\ \text{m})\sin 37^\circ = -1100\ \text{N}\cdot\text{m}$$

Note that the force exerted by the painter's feet on the ladder has the same magnitude as the force mg that Earth exerts on the painter, but it is not the same force, as it is exerted on a different object and is a contact force and not a gravitational force. That force tends to rotate the ladder clockwise about the axis of rotation (a negative torque). The force makes a 37° angle relative to a line from the axis of rotation to the place where the force is exerted.

(b) We now choose the axis of rotation parallel to the wall at the top of the ladder where it touches the wall. The torque produced by the force exerted by the painter's feet on the ladder is

$$\tau = +F_{\text{P on L}} l \sin\theta = +(m_p g) l \sin\theta$$
$$= +(75\ \text{kg})(9.8\ \text{N/kg})(3.6\ \text{m})\sin 143^\circ$$
$$= +1600\ \text{N}\cdot\text{m}$$

When we choose the axis of rotation at the top of the ladder, the downward force exerted by the painter's feet on the ladder tends to rotate the ladder counterclockwise about the axis at the top (a positive torque). This force makes a 143° angle with respect to a line from the axis of rotation to the place where the force is exerted.

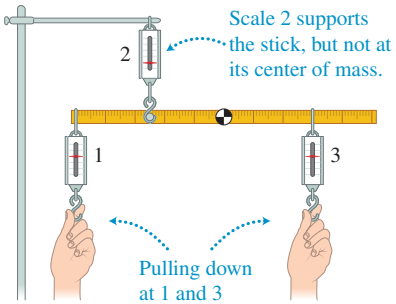
Note that the torque depends on where we place the axis of rotation. You cannot do torque calculations without carefully defining the axis of rotation.

Try it yourself Write an expression for the torque produced by the upward normal force exerted by the floor on the ladder about the same two axes: (a) at the base of ladder and (b) at the top of the ladder.

Answer (a) The torque will be 0 at the bottom, because the normal force passes through the axis. (b) About the axis at the top of the ladder, the torque is $\tau = -(6.0\ \text{m})N_{\text{Floor on Ladder}} \sin 37^\circ$. Note that the floor tends to push the ladder clockwise about an axis through the top of the ladder. The normal force makes a 37° angle relative to a line from the top axis to the place where the force is exerted.

REVIEW QUESTION 8.2 Give an example of a situation in which (a) a torque produced by a force is zero with respect to one choice of axis of rotation but not zero with respect to another; (b) a force is not exerted at the axis of rotation, but the torque produced by it is zero anyway; and (c) several forces produce nonzero torques on an object, but the object does not rotate.

8.3 Conditions of equilibrium



We can combine our previous knowledge of forces and our new knowledge of torque to determine under what conditions rigid bodies remain in static equilibrium, that is, at rest. Recall that we defined static equilibrium as a state in which an object *remains* at rest with respect to a particular observer in an inertial reference frame.

It is possible for an object to be at rest briefly. For example, a ball thrown upward stops for an instant at the top of its flight, but it does not remain at rest. Thus, the word *remains* is important in the expression "remains at rest"—the object has to stay where it is. The words "with respect to an observer in an inertial reference frame" are also an important part of the definition of static equilibrium. Recall from the chapter on Newtonian mechanics (Chapter 3) that if an observer is not in an inertial reference frame, an object can accelerate with respect to the observer even if the sum of the forces exerted on it is zero. In this chapter we will only consider observers who are at rest with respect to Earth, since that is the most common point of view for observing real-life situations involving static equilibrium.

We again suspend the same 0.1-kg meter stick from spring scale 2, as shown in **Figure 8.12**. However, the suspension point is no longer at the center of mass of the meter stick. You and your friend again pull on the stick at different positions with spring scales 1 and 3. When pulled as described in Observational Experiment **Table 8.3**, the stick does not rotate. Pulling at other positions while exerting the same forces, or pulling at the same positions while exerting different forces, causes the stick to rotate. We need to find a pattern in the combinations of forces and torques exerted on the meter stick that keep the stick in static equilibrium.

For most situations that we analyze in this chapter, we assume that the objects rotate in the x-y plane and that the axis of rotation goes through the origin of the coordinate system and is perpendicular to the x-y plane.

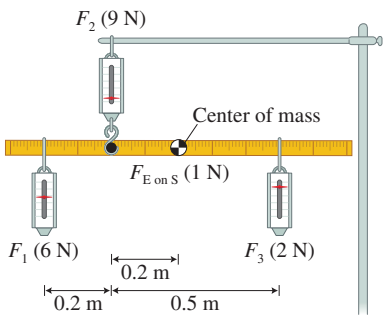


FIGURE 8.12 Multiple objects exert forces on a meter stick.

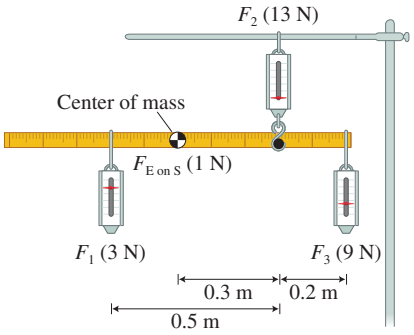
OBSERVATIONAL EXPERIMENT TABLE 8.3 Meter stick in static equilibrium



VIDEO OET 8.3

Observational experiment	Analysis
Experiment 1. Three spring scales and Earth exert forces on a meter stick at locations shown below. Examine the forces and torques exerted on the stick. Choose the axis of rotation at the place where the string from scale 2 supports the stick. This choice determines the distances in the torque equations for each force.	$\Sigma F_y = (-6.0\text{ N}) + 9.0\text{ N} + (-1.0\text{ N}) + (-2.0\text{ N}) = 0$ Counterclockwise torques: $\tau_1 = (F_1)(l_1) = (6.0\text{ N})(0.20\text{ m}) = 1.2\text{ N}\cdot\text{m}$ Clockwise torques: $\tau_2 = (F_2)(l_2) = (9.0\text{ N})(0) = 0$ $\tau_E = -(F_{E\text{ on }S})(l_{CM}) = -(1.0\text{ N})(0.2\text{ m}) = -0.2\text{ N}\cdot\text{m}$ $\tau_3 = -(F_3)(l_3) = -(2.0\text{ N})(0.50\text{ m}) = -1.0\text{ N}\cdot\text{m}$ $\Sigma\tau = \tau_1 + \tau_2 + \tau_E + \tau_3$ $= +1.2\text{ N}\cdot\text{m} + 0 - 0.2\text{ N}\cdot\text{m} - 1.0\text{ N}\cdot\text{m} = 0$

(CONTINUED)

Observational experiment	Analysis
Experiment 2. Three spring scales and Earth exert forces on a meter stick at locations shown below. Examine the forces and torques exerted on the stick. Choose the axis of rotation at the place where the string from scale 2 supports the stick.	$\Sigma F_y = -3.0\text{ N} + (-1.0\text{ N}) + 13\text{ N} + (-9.0\text{ N}) = 0$ Counterclockwise torques: $\tau_1 = (F_1)(l_1) = (3.0\text{ N})(0.50\text{ m}) = 1.5\text{ N}\cdot\text{m}$ $\tau_E = (F_{E\text{ on S}})(l_{CM}) = (1.0\text{ N})(0.3\text{ m}) = 0.3\text{ N}\cdot\text{m}$ Clockwise torques: $\tau_2 = (F_2)(l_2) = (13\text{ N})(0) = 0$ $\tau_3 = -(F_3)(l_3) = -(9.0\text{ N})(0.20\text{ m}) = -1.8\text{ N}\cdot\text{m}$ $\Sigma\tau = \tau_1 + \tau_E + \tau_2 + \tau_3$ $= +1.5\text{ N}\cdot\text{m} + 0.3\text{ N}\cdot\text{m} + 0 - 1.8\text{ N}\cdot\text{m} = 0$

Patterns

- In both cases the net force exerted on the meter stick in the vertical direction is zero: $\Sigma F_y = 0$.
- In both cases the sum of the torques exerted on the meter stick equals zero: $\Sigma\tau = 0$.

TIP Notice that you cannot determine the torque produced by a force without specifying the point at which the force is exerted on the object relative to the axis of rotation.

The first pattern in both experiments is familiar to us. It is simply Newton's second law applied to the vertical axis of the meter stick for the case of zero translational acceleration. Because the sum of the vertical forces exerted on the meter stick is zero, there is no vertical acceleration. We had no horizontal forces, so the meter stick could not accelerate horizontally. The second pattern shows that in both cases the net torque is zero and the meter stick does not start turning.

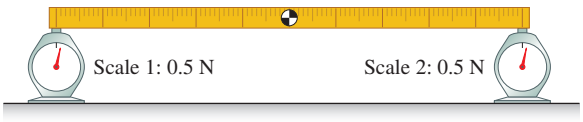
We can now summarize these conclusions as follows:

TIP Remember that all the gravitational forces exerted by Earth on the different parts of the rigid body can be combined into a single gravitational force being exerted on the center of mass of the rigid body.

Condition 1. Translational (force) condition of static equilibrium An object modeled as a rigid body is in translational static equilibrium with respect to a particular observer if it is at rest with respect to that observer and the components of the sum of the forces exerted on it in the perpendicular x- and y-directions are zero:

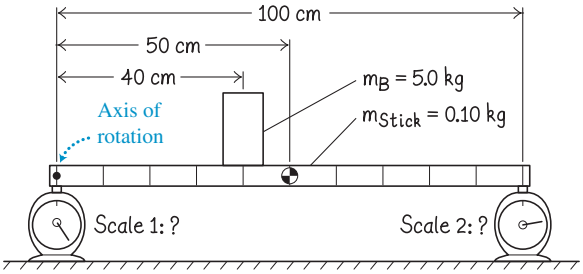
$$\Sigma F_{\text{on O}\,x} = F_{1\text{ on O}\,x} + F_{2\text{ on O}\,x} + \cdots + F_{n\text{ on O}\,x} = 0 \tag{8.2x}$$

$$\Sigma F_{\text{on O}\,y} = F_{1\text{ on O}\,y} + F_{2\text{ on O}\,y} + \cdots + F_{n\text{ on O}\,y} = 0 \tag{8.2y}$$



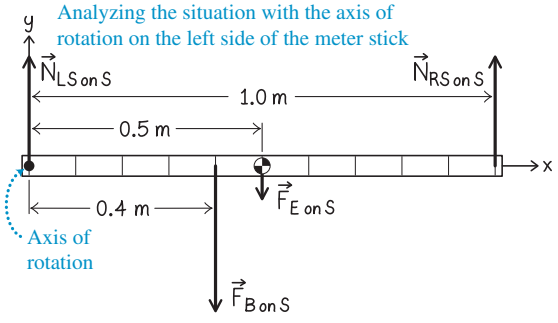
The subscript n indicates the number of forces exerted by external objects on the rigid body.

Condition 2. Rotational (torque) condition of static equilibrium A rigid body is in turning or rotational static equilibrium if it is at rest with respect to the observer and the sum of the torques $\Sigma\tau$ (positive counterclockwise torques and negative clockwise torques) about any axis of rotation produced by the forces exerted on the object is zero:



$$\Sigma\tau = \tau_1 + \tau_2 + \cdots + \tau_n = 0 \tag{8.3}$$

EXAMPLE 8.3 Testing the conditions of static equilibrium



Place the ends of a standard meter stick on two scales, as shown below. The scales each read 0.50 N. From this, we infer that the mass of the meter stick is about 0.10 kg (the gravitational force that Earth exerts on the meter stick would be $(0.10\text{ kg})(9.8\text{ N/kg}) = 1.0\text{ N}$). Predict what each scale will read if you place a 5.0-kg brick 40 cm to the right of the left scale.

Sketch and translate A labeled sketch of the situation is shown below. We choose the stick as the system of interest and use a standard *x*-*y* coordinate system. We choose the axis of rotation at the place where the left scale touches the stick. By doing this, we are making the torque produced by the normal force exerted by the left scale on the stick zero—that force is exerted exactly at the axis of rotation. With this choice, we remove one of the unknown quantities from the torque condition of equilibrium and will be able to use that condition to find the force exerted by the right scale on the meter stick.

Simplify and diagram We model the meter stick as a rigid body with a uniform mass distribution (its center of mass is at the midpoint of the stick). We model the brick as a point-like object, and assume that the scales push up on the stick at the exact ends of the stick. We then draw a force diagram showing the forces exerted on the stick by Earth, the brick, and each of the scales. As noted, the left end of the stick has been chosen as the axis of rotation.

Represent mathematically According to the conditions of static equilibrium, the sum of the forces exerted on the meter stick should equal zero, as should the sum of the torques around the axis of rotation. The gravitational force exerted by Earth and the normal force exerted by the brick on the stick both have clockwise turning ability around the axis of rotation and produce negative torques. The force exerted by the right scale on the stick has counterclockwise turning ability and produces a positive torque. The force exerted by the left scale on the stick produces zero torque since it is exerted at the axis of rotation. The two conditions of equilibrium are then the following:

Translational (force) condition ($\Sigma F_y = 0$):

$$(-F_{E\text{ on }S}) + (-F_{B\text{ on }S}) + N_{RS\text{ on }S} + N_{LS\text{ on }S} = 0$$

Rotational (torque) condition ($\Sigma\tau = 0$):

$$-F_{E\text{ on }S}(0.50\text{ m}) - F_{B\text{ on }S}(0.40\text{ m}) + N_{RS\text{ on }S}(1.00\text{ m}) = 0$$

Since none of the forces have *x*-components, we didn't apply the *x*-component form of the force condition of equilibrium.

Earth exerts a downward gravitational force on the brick of magnitude:

$$F_{E\text{ on }B} = m_B g = (5.0\text{ kg})(9.8\text{ N/kg}) \approx 50\text{ N}$$

Thus, the stick must exert a balancing 50-N upward force on the brick. According to Newton's third law ($\vec{F}_{B\text{ on }S} = -\vec{F}_{S\text{ on }B}$), the brick must exert a downward 50-N force $\vec{F}_{B\text{ on }S}$ on the stick.

Solve and evaluate We have two equations with two unknowns ($N_{RS\text{ on }S}$ and $N_{LS\text{ on }S}$). We first use the torque equilibrium condition to determine the magnitude of the force exerted by the right scale on the stick (we use 10 N/kg instead of 9.8 N/kg for simplicity):

$$-[(0.10\text{ kg})(10\text{ N/kg})](0.50\text{ m}) - [(5.0\text{ kg})(10\text{ N/kg})](0.40\text{ m}) + N_{RS\text{ on }S}(1.00\text{ m}) = 0$$

or

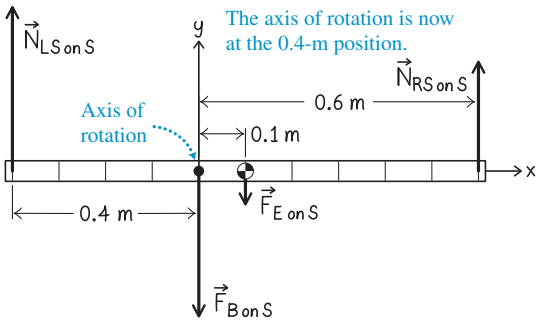
$$N_{RS\text{ on }S} = 20.5\text{ N}$$

We can use this result along with the force equilibrium condition equation to determine the magnitude of the force exerted by the left scale on the stick.

$$-(0.10\text{ kg})(10\text{ N/kg}) - (5.0\text{ kg})(10\text{ N/kg}) + 20.5\text{ N} + N_{LS\text{ on }S} = 0$$

or

$$N_{LS\text{ on }S} = 30.5\text{ N}$$



These predictions make sense because the sum of these two upward forces equals the sum of the two downward forces that Earth and the brick exert on the meter stick. Also, the force on the left end is greater because the brick is positioned closer to it, which sounds very reasonable. Performing this experiment, we find that the outcome matches the predictions.

Using a different axis of rotation Remember that we had the freedom to choose whatever axis of rotation we wanted. Let's try it again with the axis of rotation at 40 cm from the left side, the location of the brick. See the force diagram on the next page. The force condition

(CONTINUED)

of equilibrium will not change since it does not depend on the choice of the axis of rotation:

$$(-F_{\text{E on S}}) + (-F_{\text{B on S}}) + N_{\text{RS on S}} + N_{\text{LS on S}} = 0$$

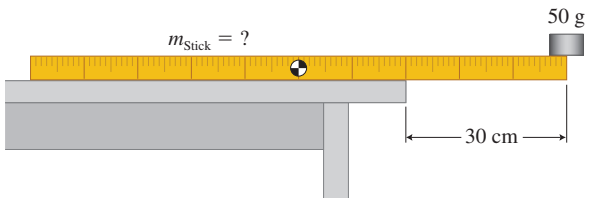
The torque condition will change:

$$[-F_{\text{E on S}}\,(0.10\text{ m})] + [-N_{\text{LS on S}}\,(0.40\text{ m})] + N_{\text{RS on S}}(0.60\text{ m}) = 0$$

Now we have two unknowns in each of the two equations and have to solve them simultaneously to determine the unknowns. This will be somewhat harder than when we chose the axis of rotation at the left end of the stick. Let's solve the force condition equation for $N_{\text{RS on S}}$ and substitute the result into the torque condition equation:

$$\begin{aligned} N_{\text{RS on S}} &= F_{\text{E on S}} + F_{\text{B on S}} - N_{\text{LS on S}} \\ \Rightarrow -F_{\text{E on S}}&(0.10\text{ m}) - N_{\text{LS on S}}(0.40\text{ m}) \\ &+ (F_{\text{E on S}} + F_{\text{B on S}} - N_{\text{LS on S}})(0.60\text{ m}) = 0 \end{aligned}$$

Combining the terms with $N_{\text{LS on S}}$ on one side, we get



$$\begin{aligned} N_{\text{LS on S}}(0.40\text{ m} + 0.60\text{ m}) &= F_{\text{E on S}}(0.50\text{ m}) + F_{\text{B on S}}(0.60\text{ m}) \\ &= (1.0\text{ N})(0.50\text{ m}) + (50\text{ N})(0.60\text{ m}) = 30.5\text{ N}\cdot\text{m} \end{aligned}$$

or $N_{\text{LS on S}} = 30.5$ N. Substituting back into the force condition equation, we find that

$$N_{\text{RS on S}} = 1.0\text{ N} + 50.0\text{ N} - 30.5\text{ N} = 20.5\text{ N}$$

These are the same results we obtained from the original choice of the axis of rotation. The choice of the axis of rotation does not affect the results. This makes sense, in the same way that choosing a coordinate system does not affect the outcome of an experiment. The concepts of axes of rotation and coordinate systems are mental constructs and should not affect the outcome of actual experiments.

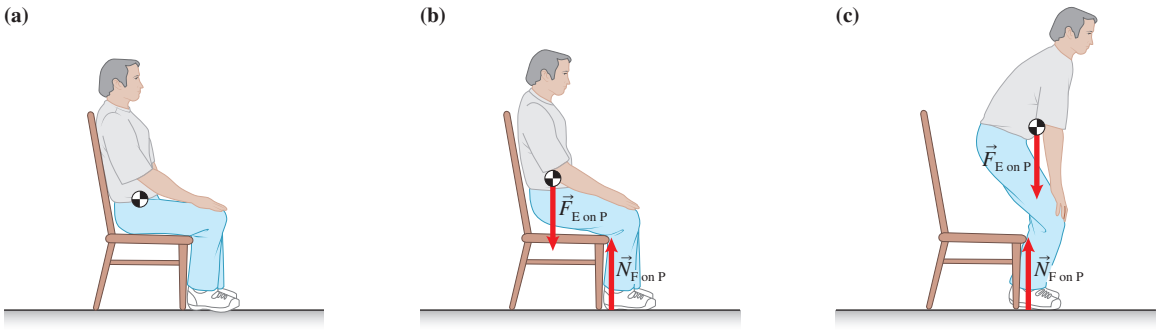
Try it yourself A uniform meter stick with a 50-g object on it is positioned as shown below. The stick extends 30 cm over the edge of the table. If you push the stick so that it extends slightly farther over the edge, it tips over. Use this result to determine the mass of the meter stick.

Answer 57 g

REVIEW QUESTION 8.3 You read the following sentence in a book: "In problem solving, put the axis at the place on the rigid body where the force you know the least about is exerted." Explain why this hint is helpful.

8.4 Center of mass

FIGURE 8.13 Where is the jumper's center of mass?



Many extended bodies are not rigid—the human body is a good example. A high jumper crossing the bar is often bent into an inverted U shape (**Figure 8.13**). Why does this shape allow her to jump higher? At the moment shown in the photo, her legs, arms, and head are below the bar as the trunk of the body passes over the top. As each part of the body passes over the bar, the rest of the body is at a lower elevation so that her center of mass is always slightly below the bar. The high jumper does not have to jump as high because she is able to reorganize her body's shape so that her center of mass passes *under* or at least not significantly over the bar.

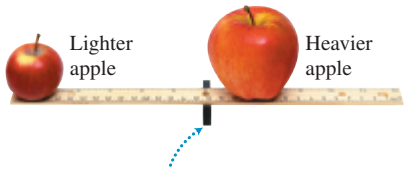
Without realizing it, we change the position of our center of mass with respect to other parts of the body quite often. Try this experiment. Sit on a chair with your back straight and your feet on the floor in front of the chair (see **Figure 8.14a**). Without using your hands, try to stand up; you cannot. No matter how hard you try, you cannot raise yourself to standing from the chair if your back is vertical.

Why can't you stand? The center of mass of an average person when sitting upright is near the front of the abdomen. Figure 8.14 explains how the location of the center of

FIGURE 8.14 Getting out of a chair without using your hands.

You sit on a chair with back straight and feet on the floor. Your center of mass is over the chair.

With your back straight as you lift yourself from the chair, the normal force exerted by the floor on your feet causes a counterclockwise torque about the center of mass. You fall backward.



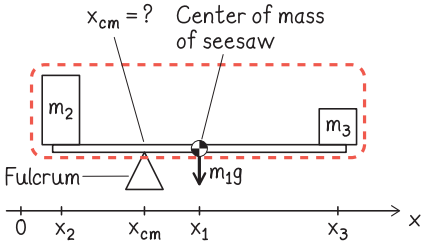
Bending forward so that your center of mass is in front of the floor's normal force causes a clockwise torque so that you can stand.

mass with respect to your feet affects whether the torques exerted on you by the two forces are able to rotate you in the desired direction.

Calculating center of mass

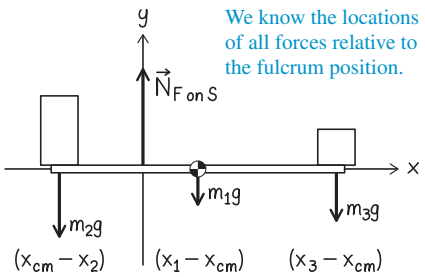
How do we know that the center of mass of a sitting person is near the abdomen? In Section 8.1 we determined the location of an object's center of mass by investigating the directions along which one needs to push the object so it does not turn while being pushed on a flat smooth surface. When pushing in this way at different locations on the object, we found that lines drawn along the directions of these pushing forces all intersected at one point: the center of mass. This is a difficult and rather impractical way to find the center of mass of something like a human. Another method that we investigated consisted of balancing the object on a pointed support. This is also not very practical with respect to humans. Is there a way to predict where an object's center of mass is without pushing or balancing it? Our goal here is to develop a theoretical method that will allow us to determine the location of the center of mass of a complex object, such as the uniform meter stick with two apples shown in **Figure 8.15**. In the next example, we start with an object that consists of three other objects: two people of different masses and a uniform seesaw whose supporting fulcrum (point of support) can be moved. To determine the location of the center of mass of a system involving two people and a uniform beam, we find a place for the fulcrum to support the seesaw and the two people so that the system remains in static equilibrium.

FIGURE 8.15 Where is the center of mass of the meter stick with two apples?



Adjust the position of the fulcrum supporting the seesaw until the system is in static equilibrium.

EXAMPLE 8.4 **Supporting a seesaw with two people**



Find an expression for the position of the center of mass of a system that consists of a uniform seesaw of mass m_1 and two people of masses m_2 and m_3 sitting at the ends of the seesaw beam ($m_2 > m_3$).

Sketch and translate The figure at right shows a labeled sketch of the situation. The two people are represented as blocks. We choose the seesaw and two blocks as the system and construct a mathematical equation that lets us calculate the center of mass of that system. We place the x-axis along the seesaw with its origin at some arbitrary position on the left side of the seesaw. The center of mass of the seesaw beam is at x_1 and the two blocks rest at x_2 and x_3. At what *position* x should we place the fulcrum under the seesaw so that the system does not rotate—so that it remains in static equilibrium? At this position, the sum of all torques exerted on the system is zero. This position is the center of mass of the three-object system.

(CONTINUED)

Simplify and diagram We model the seesaw as a rigid body and model each of the people blocks as point-like objects. Assume that the fulcrum does not exert a friction force on the seesaw. As you can see in the force diagram, we know the locations of all forces except the normal force exerted at the fulcrum. We will calculate the unknown position x_{cm} of the fulcrum so the seesaw with two people on it balances—so that it satisfies the second condition of equilibrium.

Represent mathematically Apply the torque condition of equilibrium with the axis of rotation going through the unknown fulcrum position x_{cm}. Then determine the torques around this axis produced by the forces exerted on the system. The gravitational force exerted by Earth on the center of mass of the seesaw has magnitude m_1g, is exerted a distance $x_1 - x_{cm}$ from the axis of rotation, and has clockwise turning ability. The gravitational force exerted by Earth on block 2 has magnitude m_2g, is exerted a distance $x_{cm} - x_2$ from the axis of rotation, and has counterclockwise turning ability. The gravitational force exerted by Earth on block 3 has magnitude m_3g, is exerted a distance $x_3 - x_{cm}$ from the axis of rotation, and has clockwise turning ability. The torque condition of equilibrium for the system becomes

$$m_2g(x_{cm} - x_2) - m_1g(x_1 - x_{cm}) - m_3g(x_3 - x_{cm}) = 0$$

Solve and evaluate Divide all terms of the equation by the gravitational constant g and collect all terms involving x on one side of the equation to get

$$m_2x_{cm} + m_1x_{cm} + m_3x_{cm} = m_2x_2 + m_1x_1 + m_3x_3$$

or

$$x_{cm}(m_2 + m_1 + m_3) = m_2x_2 + m_1x_1 + m_3x_3$$

Divide both sides of the equation by $(m_2 + m_1 + m_3)$ to obtain an expression for the location of the center of mass of the three-object system:

$$x_{cm} = \frac{m_1x_1 + m_2x_2 + m_3x_3}{m_1 + m_2 + m_3}$$

Let's evaluate this result. The units of x are meters. Next check some limiting cases to see if the result makes sense. Imagine that there are no people sitting on the seesaw ($m_2 = m_3 = 0$). In this case, $x_{cm} = \frac{m_1x_1}{m_1} = x_1$. The center of mass of the seesaw-only system is at the center of mass of the seesaw x_1, as it should be since we assumed its mass was uniformly distributed. Finally, if we increase the mass of one of the people on the seesaw, the location of the center of mass moves closer to that person.

Try it yourself Where is the center of mass of a 3.0-kg, 2.0-m-long uniform beam with a 0.5-kg object on the right end and a 1.5-kg object on the left?

Answer 0.8 m from the left end of the beam.

In Example 8.4 we arrived at an expression for the location of the center of mass of a three-object system where all objects were located along one straight line. We can apply the same method to a system whose masses are distributed in a two-dimensional x-y plane. For such a two-dimensional system, we get the following:

Center of mass (quantitative definition) If we consider an object as consisting of parts 1, 2, 3, . . . n whose centers of masses are located at the coordinates (x_1, y_1); (x_2, y_2); (x_3, y_3); . . . (x_n, y_n), then the center of mass of this whole object is at the following coordinates:

$$x_{cm} = \frac{m_1x_1 + m_2x_2 + m_3x_3 + \cdots + m_nx_n}{m_1 + m_2 + m_3 + \cdots + m_n}$$
$$y_{cm} = \frac{m_1y_1 + m_2y_2 + m_3y_3 + \cdots + m_ny_n}{m_1 + m_2 + m_3 + \cdots + m_n} \qquad (8.4)$$

You can think of the position of the center of mass of an object of mass M as a weighted average of the positions of parts 1, 2, 3, etc. (m_1, m_2, m_3 . . . m_n etc.), or

$$x_{cm} = \frac{m_1}{M}x_1 + \frac{m_2}{M}x_2 + \frac{m_3}{M}x_3 + \cdots + \frac{m_n}{M}x_n$$
$$y_{cm} = \frac{m_1}{M}y_1 + \frac{m_2}{M}y_2 + \frac{m_3}{M}y_3 + \cdots + \frac{m_n}{M}y_n$$

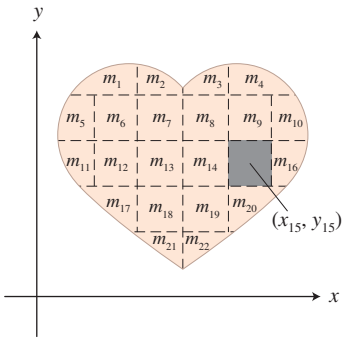
Using Eq. (8.4) for an object with a continuous mass distribution is difficult and involves calculus. For example, in the first section we found the position of the center of mass of a cardboard heart empirically. Now we can calculate its position mathematically (**Figure 8.16**). We subdivide the cardboard into many tiny sections and insert the mass and position of each section into Eq. (8.4), and then add all the terms in the numerator and denominator together to determine the center of mass of the cardboard. For example, section 15 would contribute a term $m_{15}x_{15}$ in the numerator of the x_{cm} equation and a term m_{15} in the denominator. Usually, you will be given the location of the center of mass of such continuous mass distributions.

Knowledge of the center of mass helps you answer many questions: Why if you walk with a heavy backpack do you fall more easily? Why does a baseball bat have an elongated, uneven shape? Why do ships carry heavy loads in the bottom rather than near the top of the ship?

Mass distribution and center of mass

The term "center of mass" is deceiving. It might make you think that the center of mass of an object is located at a place where there is an equal amount of mass on each side. However, this is not necessarily the case. Consider again a uniform seesaw (see **Figure 8.17a**). Suppose that the mass of the seesaw is 20 kg, the length is 3.0 m, the mass of the person on the left end (m_1) is 60 kg, and the mass of the person on the right end (m_3) is 20 kg. Where is the center of mass of this two-person seesaw system, and how much mass is on the left side and the right side of the center of mass?

To find the center of mass, we need a coordinate system with an origin. The origin can be anywhere; we will put it at the location of the more massive person on the left side. The center of mass is then



$$x_{cm} = \frac{m_1x_1 + m_2x_2 + m_3x_3}{m_1 + m_2 + m_3}$$

$$= \frac{(60\text{ kg} \times 0\text{ m}) + (20\text{ kg} \times 1.5\text{ m}) + (20\text{ kg} \times 3.0\text{ m})}{60\text{ kg} + 20\text{ kg} + 20\text{ kg}} = 0.9\text{ m}$$

The seesaw will balance about a fulcrum located 0.9 m from m_1 and 2.1 m from m_2 (see Figure 8.17b). We see that the masses are not equal. The mass on the left side of the center of mass is much greater than on the right side—66 kg versus 34 kg. The larger mass on the left is a shorter distance from the center of mass than the smaller masses on the right, which on average are farther from the center of mass. However, the product of mass and distance on each side balances out, causing torques of equal magnitude. We could rename the center of mass as "the center of torque" to reflect the essence of the concept, but since this is not the term used in physics, we will continue to use the term center of mass.

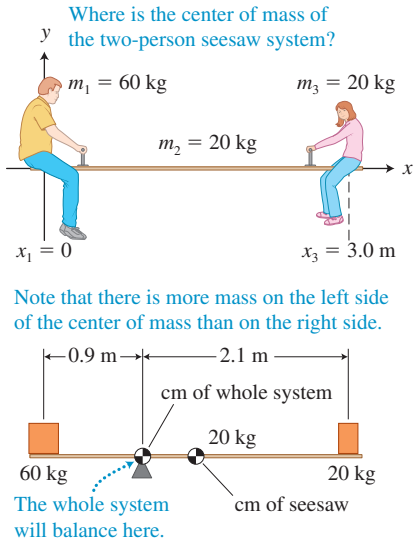
REVIEW QUESTION 8.4 Jade says that the mass of an object is evenly distributed around the location of its center of mass. Do you agree with her? If you disagree, how would you convince her of your opinion?

FIGURE 8.16 Finding the center of mass of a continuous mass distribution.

$$x_{cm} = \frac{m_1x_1 + \ldots + m_{15}x_{15} + \ldots + m_{22}x_{22}}{m_1 + \ldots + m_{15} + \ldots + m_{22}}$$

$$y_{cm} = \frac{m_1y_1 + \ldots + m_{15}y_{15} + \ldots + m_{22}y_{22}}{m_1 + \ldots + m_{15} + \ldots + m_{22}}$$

FIGURE 8.17 The masses on each side of a system's center of mass are unequal.



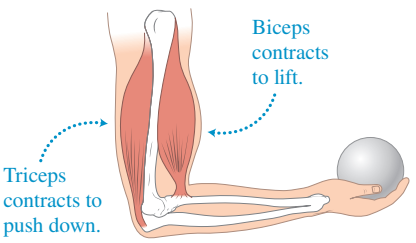


FIGURE 8.18 Muscles in the upper arm lift and push down on the forearm.

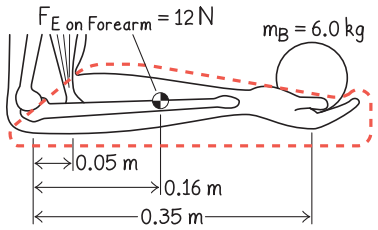
8.5 Skills for analyzing situations using equilibrium conditions

We often use the equations of equilibrium to determine one or two unknown forces if all other forces exerted on an object of interest are known. Consider the muscles of your arm when you lift a heavy ball or push down on a desktop (**Figure 8.18**). When

you hold a ball in your hand, your biceps muscle tenses and pulls up on your forearm in front of the elbow joint. When you push down with your hand on a desk, your triceps muscle tenses and pulls up on a protrusion of the forearm behind the elbow joint. The equations of equilibrium allow you to estimate these muscle tension forces—see the next example, which describes a general method for analyzing static equilibrium problems. The right side of the table applies the general strategies to the specific problem provided.

PROBLEM-SOLVING STRATEGY 8.1 Applying static equilibrium conditions

EXAMPLE 8.5 Using the biceps muscle to lift

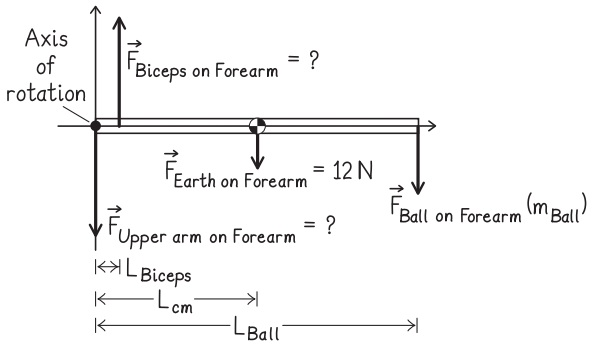


Imagine that you hold a 6.0-kg lead ball in your hand with your arm bent. The ball is 0.35 m from the elbow joint. The biceps muscle attaches to the forearm 0.050 m from the elbow joint and exerts a force on the forearm that allows it to support the ball. The center of mass of the 12-N forearm is 0.16 m from the elbow joint. Estimate the magnitude of (a) the force that the biceps muscle exerts on the forearm and (b) the force that the upper arm exerts on the forearm at the elbow.

Sketch and translate

- Construct a labeled sketch of the situation; mark knowns and unknowns. Choose an axis of rotation.
- Choose a system for analysis.

We choose the axis of rotation to be where the upper arm bone (the humerus) presses on the forearm at the elbow joint. This will eliminate from the torque equilibrium equation the unknown force that the upper arm exerts on the forearm.



We choose the system of interest to be the forearm and hand.

Simplify and diagram

- Decide whether you will model the system as a rigid body or as a point-like object.
- Construct a force diagram for the system. Include the chosen coordinate system and the axis of rotation (the origin of the coordinate system).

Model the system as a rigid body and draw a force diagram for the forearm and hand.

Represent mathematically

- Use the force diagram to apply the conditions of equilibrium.

$$\Sigma\tau = 0$$

$$(F_{\text{UA on FA}})(0) + (F_{\text{Biceps on FA}})(L_{\text{Biceps}} \sin 90^\circ) + (-F_{\text{E on FA}}(L_{\text{cm}} \sin 90^\circ)) + (-F_{\text{Ball on FA}}(L_{\text{Ball}} \sin 90^\circ)) = 0$$

$$\Sigma F_y = 0$$

$$(-F_{\text{UA on FA}}) + F_{\text{Biceps on FA}} + (-F_{\text{E on FA}}) + (-F_{\text{Ball on FA}}) = 0$$

Solve and evaluate

- Solve the equations for the quantities of interest.
- Evaluate the results. Check to see if their magnitudes are reasonable and if they have the correct signs and units. Also see if they have the expected values in limiting cases.

Substitute $\sin 90° = 1.0$ and rearrange the torque equation to find $F_{\text{Biceps on FA}}$.

$$F_{\text{Biceps on FA}} = [\,(F_{\text{E on FA}})(L_{\text{cm}}) + (F_{\text{Ball on FA}})(L_{\text{Ball}})\,]/L_{\text{Biceps}}$$
$$= [\,(12\text{ N})(0.16\text{ m}) + (59\text{ N})(0.35\text{ m})\,]/(0.050\text{ m}) = 450\text{ N}$$

Use the force equation to find $F_{\text{UA on FA}}$:

$$F_{\text{UA on FA}} = F_{\text{Biceps on FA}} - F_{\text{E on FA}} - F_{\text{Ball on FA}}$$
$$= 450\text{ N} - 12\text{ N} - 59\text{ N} = 380\text{ N}$$

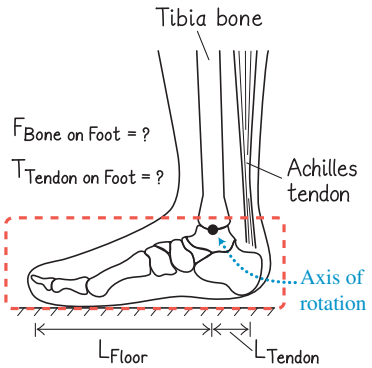
The 450-N force exerted by the biceps on the forearm is much greater than the 59-N force exerted by the ball on the forearm. This difference occurs because the force exerted by the biceps is applied much closer to the axis of rotation than the force exerted by the lead ball.

If the center of mass of the forearm were farther from the elbow, the biceps would have to exert an even larger force.

Try it yourself How would the force exerted by the biceps on the forearm change if the biceps were attached to the forearm farther from the elbow?

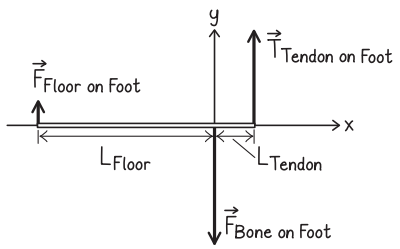
Answer

A longer L_{Biceps} in the torque equilibrium equation would mean that the biceps muscle would need to exert a smaller force on the forearm when lifting something.



Standing on your toes

Most injuries to the Achilles tendon occur during abrupt movement, such as jumps and lunges. However, we will analyze what happens to your Achilles tendon in a less stressed situation.



EXAMPLE 8.6 **Standing with slightly elevated heel**

Suppose you stand on your toes with your heel slightly off the ground. In order to do this, the larger of the two lower leg bones (the tibia) exerts a force on the ankle joint where it contacts the foot. The Achilles tendon simultaneously exerts a force on the heel, pulling up on it in order for the foot to be in static equilibrium. What is the magnitude of the force that the tibia exerts on the ankle joint? What is the magnitude of the force that the Achilles tendon exerts on the heel?

Sketch and translate First we sketch the foot with the Achilles tendon and the tibia. We choose the foot as the system of interest. Three forces are exerted on the foot: the tibia is pushing down on the foot at the ankle joint; the floor is pushing up on the ball of the foot and the toes; and the Achilles tendon is pulling up on the heel. We choose the axis of rotation as the place where the tibia presses against the foot.

Simplify and diagram Model the foot as a very light rigid body. The problem says that the foot is barely off the ground, so we will neglect the angle between the foot and the ground and consider the foot horizontal. The gravitational force exerted on the foot by Earth is quite small compared with the other forces that are being exerted on it, so we will ignore it. A force diagram for the foot is shown at right. When you are standing on the ball and toes of both feet, the floor exerts an upward force on each foot equal to half the magnitude of the gravitational force that Earth exerts on your entire body: $F_{\text{Floor on Foot}} = \dfrac{m_{\text{Body}}g}{2}$. The Achilles tendon pulls up on the heel of the foot, exerting a force $T_{\text{Tendon on Foot}}$. The tibia bone in the lower leg pushes down on the ankle joint exerting a force $F_{\text{Bone on Foot}}$.

Represent mathematically Let's apply the conditions of equilibrium to this system. Note that the distance from the toes to the joint L_{Floor} is somewhat longer than the distance from the joint to the Achilles tendon attachment point L_{Tendon}. The torque condition of equilibrium becomes

$$+[\,T_{\text{Tendon on Foot}}(L_{\text{Tendon}})\,] + F_{\text{Bone on Foot}}(0) - \frac{m_{\text{Body}}g}{2}(L_{\text{Floor}}) = 0$$

$$\Rightarrow T_{\text{Tendon on Foot}} = \frac{m_{\text{Body}}g}{2}\left(\frac{L_{\text{Floor}}}{L_{\text{Tendon}}}\right)$$

(CONTINUED)

Now, apply the y-scalar component of the force condition of equilibrium:

$$\Sigma F_y = T_{\text{Tendon on Foot}} + (-F_{\text{Bone on Foot}}) + \frac{m_{\text{Body}}g}{2} = 0$$

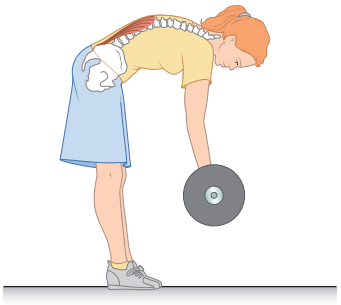
$$\Rightarrow F_{\text{Bone on Foot}} = T_{\text{Tendon on Foot}} + \frac{m_{\text{Body}}g}{2}$$

Solve and evaluate The distance from the place where the bone contacts the foot to where the floor contacts the foot is about 5 times longer than the distance from the bone to where the tendon contacts the foot. Consequently, the force that the Achilles tendon exerts on the foot is about

$$T_{\text{Tendon on Foot}} = \frac{m_{\text{Body}}g}{2}\left(\frac{L_{\text{Floor}}}{L_{\text{Tendon}}}\right) = \frac{m_{\text{Body}}g}{2}(5) = \frac{5}{2}m_{\text{Body}}g$$

or two and a half times the gravitational force that Earth exerts on the body. Using $g = 10\ \text{N/kg}$ for a 70-kg person, this force will be about 1750 N. That's a very large force for something as simple as standing with your heel slightly elevated! The force exerted on the joint by the leg bone would be

$$F_{\text{Bone on Foot}} = T_{\text{Tendon on Foot}} + \left(\frac{m_{\text{Body}}g}{2}\right)$$



$$= 1750\ \text{N} + 350\ \text{N} = 2100\ \text{N}$$

This force is three times the weight of the person! The forces are much greater when moving. Thus, every time you lift your foot to walk, run, or jump, the tendon tension and joint compression are several times greater than the gravitational force that Earth exerts on your entire body.

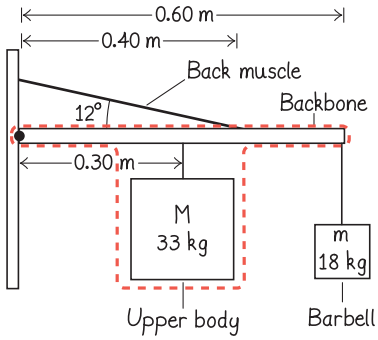
Try it yourself Estimate the increase in the magnitude of the force exerted by the Achilles tendon on the foot of the person in this example if his mass were 90 kg instead of 70 kg.

Answer An increase of at least 500 N (110 lb).

FIGURE 8.19 A bad way to lift.

Lifting from a bent position

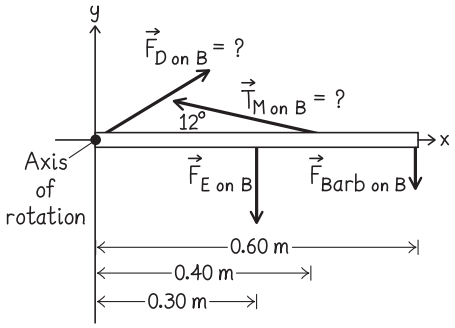
Back problems often originate with improper lifting techniques—a person bends over at the waist and reaches to the ground to pick up a box or a barbell. In Figure 8.19, the barbell pulls down on the woman's arms far from the axis of rotation of her upper body about her hip area. This downward pull causes a large clockwise torque on her upper body. To prevent her from tipping over, her back muscles must exert a huge force on the backbone, thus producing an opposing counterclockwise torque. This force exerted by the back muscles compresses the disks that separate vertebrae and can lead to damage of the disks, especially in the lower back. We can use the equilibrium equations to estimate the forces and torques involved in such lifting.



EXAMPLE 8.7 Lifting incorrectly from a bent position

Estimate the magnitude of the force that the back muscle in the woman's back in Figure 8.19 exerts on her backbone and the force that her backbone exerts on the disks in her lower back when she lifts an 18-kg barbell. The woman's mass is 55 kg. Model the woman's upper body as a rigid body.

- The back muscle attaches two-thirds of the way from the bottom of her $l = 0.60$ m backbone and makes a 12° angle relative to the horizontal backbone.
- The mass of her upper body is $M =$ 33 kg centered at the middle of the backbone and has uniform mass distribution. The axis of rotation is at the left end of the backbone and represents one of the disks in the lower back.



Sketch and translate

The figure at right is our mechanical model of a person lifting a barbell. We want to estimate the magnitudes of the force $T_{\text{M on B}}$ that the back muscle exerts on the backbone and the force $F_{\text{D on B}}$ that the disk in the lower back exerts on the backbone. The force that the disk exerts on the bone is equal in magnitude to the force exerted by the backbone on the disk. The upper body (including the backbone) is the system of interest, but we consider the back muscle to be external to the system since we want to focus on the force it exerts on the backbone. The hinge where the upper body meets the lower body is the axis of rotation.

Simplify and diagram We next draw a force diagram for the upper body. The gravitational force that Earth exerts on the upper body $F_{\text{E on B}}$ at its center of mass is $Mg = (33\ \text{kg})(9.8\ \text{N/kg}) = 323\ \text{N}(73\ \text{lb})$. The barbell exerts a force on the upper body equal to $mg = (18\ \text{kg}) \times (9.8\ \text{N/kg}) = 176\ \text{N}(40\ \text{lb})$. Because of our choice of axis of rotation, the force exerted by the disk on the upper body $F_{\text{D on B}}$ will not produce a torque. The gravitational force exerted by Earth on the upper body and

the force that the barbell exerts on the upper body have clockwise turning ability, while the tension force exerted by the back muscles on the upper body has counterclockwise turning ability.

Represent mathematically The torque condition of equilibrium for the upper body is

$$\begin{aligned}\Sigma\tau &= +(F_{D\text{ on }B})(0) + [-(Mg)(l/2)\sin 90^\circ] \\ &\quad + (T_{M\text{ on }B})(2l/3)\sin 12^\circ + [-(F_{Barb\text{ on }B})(l)\sin 90^\circ] \\ &= 0\end{aligned}$$

The x- and y-component forms of the force condition of equilibrium for the backbone are

$$\Sigma F_x = F_{D\text{ on }B\,x} + (-T_{M\text{ on }B}\cos 12^\circ) = 0$$
$$\Sigma F_y = F_{D\text{ on }B\,y} + T_{M\text{ on }B}\sin 12^\circ + (-mg) + (-Mg) = 0$$

where $F_{D\text{ on }B\,x}$ and $F_{D\text{ on }B\,y}$ are the scalar components of the force that the disk exerts on the upper body.

Solve and evaluate We can solve the torque equation immediately to determine the magnitude of the force that the back muscle exerts on the backbone:

$$T_{M\text{ on }B} = \frac{(Mg)(l/2)(\sin 90^\circ) + (mg)(l)\sin 90^\circ}{(2l/3)(\sin 12^\circ)}$$

Note that the backbone length l in the numerator and denominator of all of the terms in this equation cancels out. Thus,

$$\begin{aligned}T_{M\text{ on }B} &= \frac{(Mg)(1/2)(\sin 90^\circ) + (mg)(1)\sin 90^\circ}{(2/3)(\sin 12^\circ)} \\ &= \frac{(323\text{ N})(0.50)(1.0) + (176\text{ N})(1)(1.0)}{(0.667)(0.208)} \\ &= 2432\text{ N}\ (547\text{ lb})\end{aligned}$$

We then find $F_{D\text{ on }B\,x}$ from the x-component force equation:

$$\begin{aligned}F_{D\text{ on }B\,x} &= +T_{M\text{ on }B}\cos 12^\circ \\ &= +(2432\text{ N})\cos 12^\circ = +2380\text{ N}\end{aligned}$$

and $F_{D\text{ on }B\,y}$ from the y-component force equation:

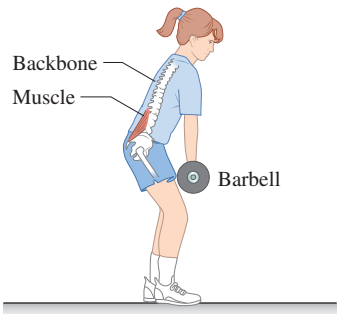
$$\begin{aligned}F_{D\text{ on }B\,y} &= +Mg + mg - T_{M\text{ on }B}\sin 12^\circ \\ &= +323\text{ N} + 176\text{ N} - (2432\text{ N})(\sin 12^\circ) = -7\text{ N}\end{aligned}$$

Thus, the magnitude of $F_{D\text{ on }B}$ is

$$F_{D\text{ on }B} = \sqrt{(2380\text{ N})^2 + (-7\text{ N})^2} = 2380\text{ N}\ (540\text{ lb})$$

The direction of $\vec{F}_{D\text{ on }B}$ can be determined using trigonometry:

$$\tan\theta = \frac{F_{D\text{ on }B\,y}}{F_{D\text{ on }B\,x}} = \frac{-7\text{ N}}{2380\text{ N}} = -0.0029$$



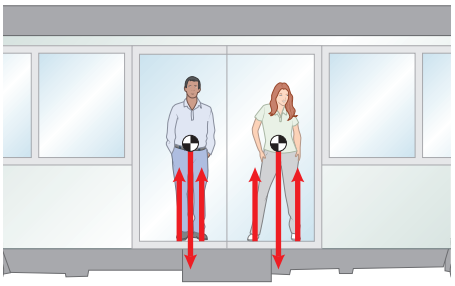
or $\theta = 0.17^\circ$ below the horizontal. We've found that the back muscles exert a force more than four times the gravitational force that Earth exerts on the person and that the disks of the lower back are compressed by a comparable force.

Try it yourself Suppose that a college football lineman stands on top of a 1-inch-diameter circular disk. How many 275-lb linemen, one on top of the other, would exert the same compression force on the disk as that exerted on the woman's disk when she lifts the 40-lb barbell?

Answer The magnitude of the force exerted on the vertebral disk is equivalent to two linemen (2×275 lb = 550 lb) standing on the 1-inch-diameter disk.

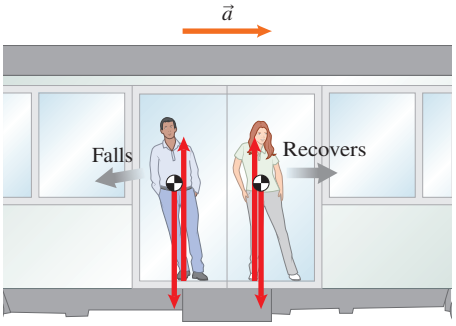
To lift correctly, keep your back more vertical with the barbell close to your body, as in **Figure 8.20**. Bend your knees and lift with your legs. With this orientation, the back muscle exerts one-third of the force that is exerted when lifting incorrectly. The disks in the lower back undergo one-half the compression they would experience from lifting incorrectly.

FIGURE 8.20 A better way to lift things.



REVIEW QUESTION 8.5 You are trying to hold a heavy dumbbell in one hand so that your arm is perpendicular to your body. Why is it easier to hold it with a bent arm than with a straight arm?

8.6 Stability of equilibrium



Often, objects can remain in equilibrium for a long time interval—you can sit comfortably for a long time on a living room couch without tipping. But sometimes equilibrium is achieved for only a short time interval—think of sitting on a chair and tilting it backward too far onto its rear legs.

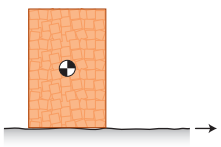
FIGURE 8.21 Balancing on the subway.

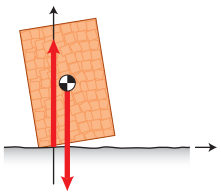
(a) The train is at rest.

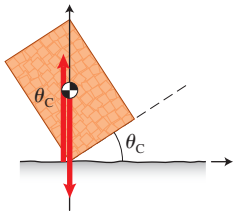
(b) The train is accelerating.

Equilibrium and tipping objects

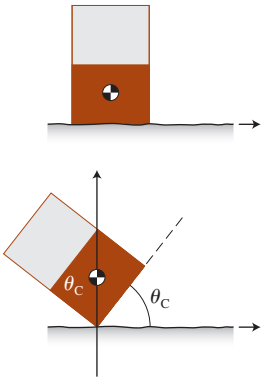
You have probably observed that it is easier to balance and avoid falling while standing in a moving bus or subway train if you spread your feet apart in the direction of motion. By doing this you are increasing the **area of support**, the area of contact between an object and the surface it is supported by. To understand area of support, consider two people riding the subway (see **Figure 8.21**).







In Figure 8.21a, the man's feet are close together, whereas the woman's feet are farther apart. When the train accelerates toward the right, as shown in Figure 8.21b, the two people tilt to the left. The man falls over because the gravitational force exerted by Earth on his body is outside the area of support provided by his feet. The woman recovers because the gravitational force still points between her feet. These patterns lead us to a tentative rule about tipping:



> For an object in static equilibrium, if a vertical line passing through the object's center of mass is within the object's area of support, the object does not tip. If the line is not within the area of support, the object tips.

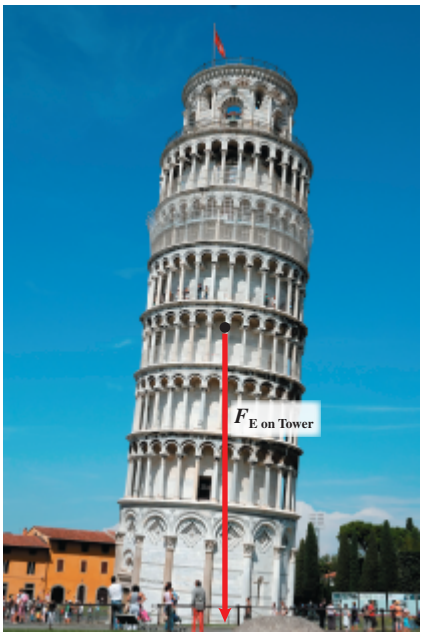
If this is a general rule, then we can use it to predict the angle at which an object with a known center of mass will tip over (see Testing Experiment **Table 8.4**).

TESTING EXPERIMENT TABLE 8.4 Testing our tentative rule about tipping

VIDEO TET 8.4

Testing experiment	Prediction	Outcome
Experiment 1. Place a full box of crackers on a flat but rough surface. Its center of mass is at its geometric center. The box's height is 20 cm and the bottom surface is 13 cm × 6.5 cm.	1. The center of mass of a full box of crackers is at its geometric center. 	
Tilt the box along the 13-cm side a little and release it.	2. When you release the slightly tilted box, it returns to the vertical position because of the torque due to the gravitational force exerted by Earth. 	The box returns to the vertical position.
Tilt the box at larger and larger angles. Predict the angle at which the box will tip.	3. When you tilt the box more and more, eventually the line defined by the gravitational force passes over the support point for the box at its bottom edge. Tilting the box more than this critical angle causes it to tip over. 	
	4. For a box with a side of 13 cm and a height of 20 cm, this angle will be $\theta_C = \tan^{-1}(13\text{ cm}/20\text{ cm}) = 33°$.	The outcome matches the prediction.

Testing experiment	Prediction	Outcome
Experiment 2. Repeat the experiment, but this time replace the crackers with a wooden block of the same mass. The block takes up about half the space that the crackers of the same mass did. Predict the angle at which the box will tip.	The center of mass should now be about one-fourth of the way from the bottom (if we neglect the mass of the box). The critical tilt angle should now be $\theta_C = \tan^{-1}(13\text{ cm}/10\text{ cm}) = 52°$. 	The outcome matches the prediction within experimental uncertainty (about 1°).



Conclusion

The outcomes are consistent with the predictions. We've increased our confidence in the tipping rule: for an object to be in static equilibrium, the line defined by the gravitational force exerted by Earth must pass within the object's area of support. If it is not within the area of support, the object tips over.

We now know that an object will tip if it is tilted so that the gravitational force passes beyond its area of support. If the area of support is large or if the center of mass is closer to the ground, more tipping is possible without the object falling over—it is more stable. This idea is regularly used in building construction. Tall towers (like the Eiffel Tower) have a wide bottom and a narrower top. The Leaning Tower of Pisa does not tip because a vertical line through its center of mass passes within the area of support (**Figure 8.22**).

The equilibrium of a system is stable against tipping if the vertical line through its center of mass passes through the system's area of support.

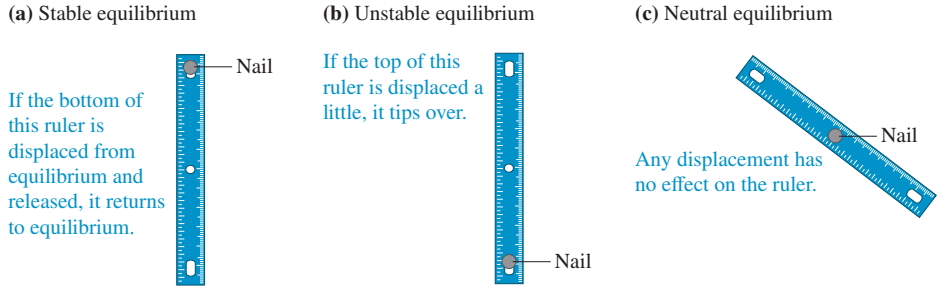


FIGURE 8.22 Because $F_{\text{E on Tower}}$ passes through the base of the tower, the Leaning Tower of Pisa does not tip over.

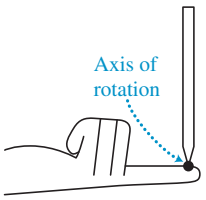
Equilibrium and rotating objects

Objects that can rotate around a fixed axis can also have either stable or unstable equilibria. Consider a ruler with several holes in it. If you hang the ruler on a nail using a hole near one end, it hangs as shown in **Figure 8.23a**. If you pull the bottom of the ruler to the side and release it, the ruler swings back and forth with decreasing maximum displacement from the equilibrium position, but eventually hangs straight down. This equilibrium position is called *stable* because the ruler always tries to return to that position if free to rotate. However, if you turn the ruler 180° so that the axis of rotation is at the bottom of the ruler (see Figure 8.23b), it can stay in this position only if very carefully balanced. If disturbed, the ruler swings down and never returns. In this case the ruler is in *unstable* equilibrium.

FIGURE 8.23 Stable, unstable, and neutral equilibrium.

The stability or lack of stability can be understood by considering the torque around the axis of rotation due to the force exerted by Earth on the object. In both positions a and b, the sum of the forces exerted on the ruler by Earth and by the nail is zero. The difference is that in the first case the center of mass is *below the axis of rotation*; in the second case it is *above the axis of rotation*. Torques produced by gravitational forces tend to lower the center of mass of objects. In other words, if it is possible for the object to rotate so that its center of mass becomes lower, it will tend to do so.

If we hang the ruler using the center hole (Figure 8.23c), it remains in whatever position we leave it. Both the force exerted by the nail and the gravitational force exerted by Earth produce zero torques. This is called *neutral* equilibrium.



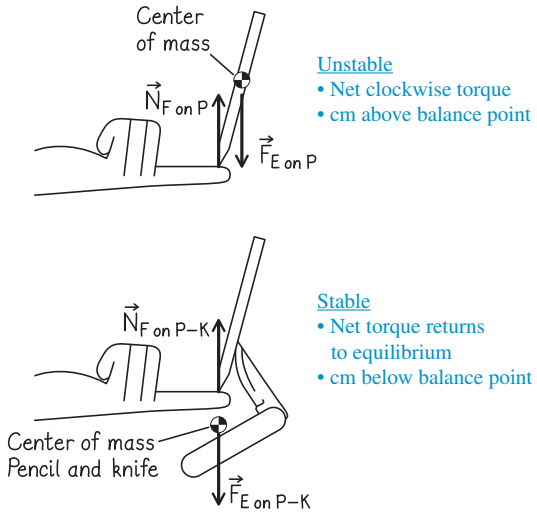
The equilibrium of a system is stable against rotation if the center of mass of the rotating object is below the axis of rotation.

CONCEPTUAL EXERCISE 8.8 Balancing a pencil

Is it possible to balance with stable equilibrium the pointed tip of a pencil on your finger?

Sketch and translate The figure below shows a sketch of the situation.

Simplify and diagram The forces exerted on the pencil are shown at right. The tip of the pencil is the axis of rotation. When the pencil is tilted by only a small angle, the line defined by the gravitational force exerted by Earth on the pencil is not within the area of support of the pencil (which is just the pencil tip). This equilibrium is unstable. Having the center of mass *above* the axis of rotation leads to this instability. To make it stable, we need to lower the center of mass to below the axis of rotation. We can do it by attaching a pocketknife to the pencil, as shown below. Notice that the massive part of the knife is below the tip of the pencil and so is the center of mass of the system. Then when the pencil tilts, the torque due to the gravitational force brings it back to the equilibrium position.



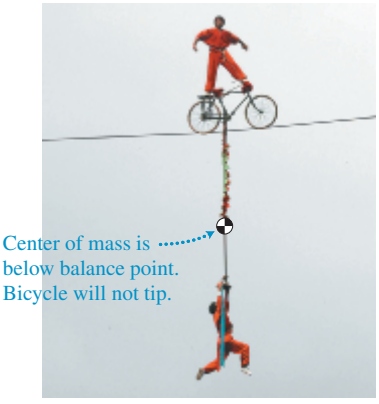


FIGURE 8.24 Balancing a bicycle on a high wire may not be as dangerous as it looks.

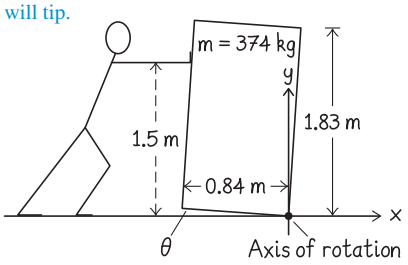
TIP Always try to understand new situations in terms of ideas we have already discussed. The trick of balancing the pencil by adding a pocketknife can be understood with the rules we expressed above: (1) the equilibrium is most stable when the center of mass of the system is in the lowest possible position or, equivalently, (2) when the gravitational potential energy of the system has the smallest value.

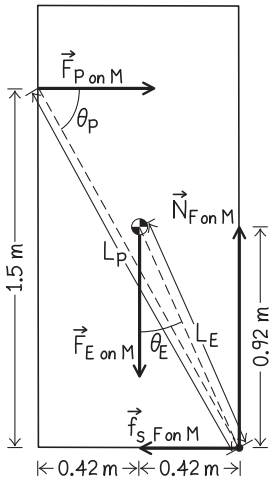
The rules we have learned about equilibrium and stability have many applications, including circus tricks. Think about where the center of mass is located for the bicycle and the two people shown in **Figure 8.24**. Another application involves vending machines.



EXAMPLE 8.9 Tipping a vending machine

According to the U.S. Consumer Product Safety Commission, tipped vending machines caused 37 fatalities between 1978 and 1995 (2.2 deaths per year). Why is tipping vending machines so dangerous? A typical vending machine is 1.83 m high, 0.84 m deep, and 0.94 m wide and has a mass of 374 kg. It is supported by a leg on each of the four corners of its base. (a) Determine the horizontal pushing force you need to exert on its front surface 1.5 m above the floor in order to just lift its front feet off the surface (so that it will be supported completely by its back two feet). (b) At what critical angle would it fall forward?

Sketch and translate



Find the angle θ at which the vending machine will tip.

(a) See the sketch of the situation at right. The axis of rotation is through the back support legs of the vending machine.

Simplify and diagram

Model the vending machine as a rigid body. Three objects exert forces on the vending machine (shown in the side view force diagram at right; the tilt is not shown since the vending machine is barely off the floor): the person exerting force $\vec{F}_{\text{P on M}}$ on the machine, Earth exerting gravitational force $\vec{F}_{\text{E on M}}$, and the floor exerting a force on the machine that we represent with two vector components: normal force $\vec{N}_{\text{F on M}}$ and static friction force $\vec{f}_{\text{s F on M}}$ on the machine.

Represent mathematically

(a) We use the torque condition of equilibrium to analyze the force needed to tilt the vending machine until the front legs are just barely off the floor. The force exerted by the person has a clockwise turning ability, while the gravitational force has counterclockwise turning ability. The force exerted by the floor on the back legs does not produce a torque, since it is exerted at the axis of rotation.

$$-F_{\text{P on M}}L_{\text{P}}\sin\theta_{\text{P}} + F_{\text{E on M}}L_{\text{E}}\sin\theta_{\text{E}} + N_{\text{F on M}}(0) + f_{\text{s F on M}}(0) = 0$$

(b) We can apply the analysis in Table 8.4 for this situation:

$$\theta_{\text{C}} = \tan^{-1}\left(\frac{\text{depth}}{\text{height}}\right)$$

Solve and evaluate (a) Using the torque equation, we can find the normal force that the person needs to exert on the vending machine to just barely lift its front off the floor:

$$-F_{\text{P on M}}L_{\text{P}}\left(\frac{1.5\text{ m}}{L_{\text{P}}}\right) + (3700\text{ N})L_{\text{E}}\left(\frac{0.42\text{ m}}{L_{\text{E}}}\right) + N_{\text{F on M}}(0) + f_{\text{s F on M}}(0) = 0$$

or $F_{\text{P on M}} = 1000$ N or 220 lb.

(b) We find that the critical tipping angle is

$$\theta_{\text{tipping}} = \tan^{-1}\left(\frac{\text{depth}}{\text{height}}\right) = \tan^{-1}\left(\frac{0.84\text{ m}}{1.83\text{ m}}\right) \approx 24°$$

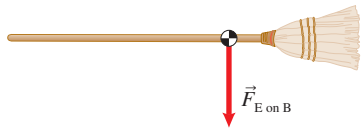
Both answers seem reasonable.

Try it yourself Determine how hard you need to push against the vending machine to keep it tilted at a 25° angle above the horizontal.

Answer 0 N. A vertical line through the center of mass passes through the axis of rotation, so the net torque about that axis is zero. However, this equilibrium is unstable and represents a dangerous situation.

The chance of being injured by a tipped vending machine is small since a large force must be exerted on it to tilt it up, and it must be tilted at a fairly large angle before it reaches an unstable equilibrium. A more common danger is falling bookcases in regions subject to earthquakes. The base of a typical 2.5-m-tall bookcase is less than 0.3 m deep. The shelves above the base that are filled with books are the same size as the base. If tilted by just

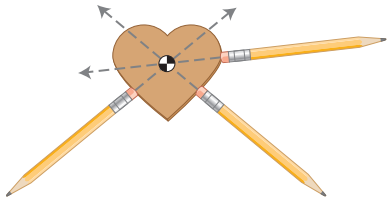
$$\theta_{\text{C}} = \tan^{-1}\left(\frac{\text{depth}}{\text{height}}\right) \approx \tan^{-1}\left(\frac{0.15\text{ m}}{1.25\text{ m}}\right) \approx 7°$$



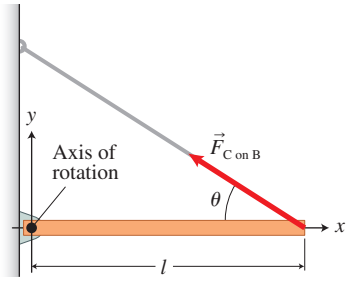
the bookcase can tip over. In earthquake-prone regions, people often attach a bracket to the top back of the bookcase and then anchor it to the wall.

REVIEW QUESTION 8.6 Why is a ball hanging by a thread in stable equilibrium, while a pencil balanced on its tip is in unstable equilibrium?

Summary



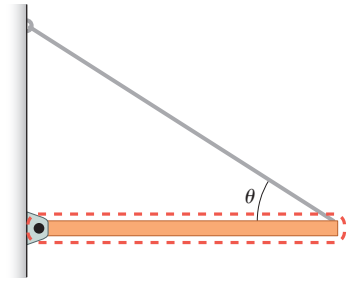
Center of mass The gravitational force that Earth exerts on an object can be considered to be exerted entirely on the object's center of mass.

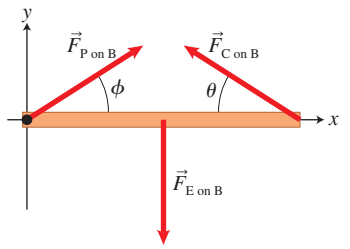


$$x_{\text{cm}} = \frac{m_1x_1 + m_2x_2 + m_3x_3 + \cdots + m_nx_n}{m_1 + m_2 + m_3 + \cdots + m_n}$$

$$y_{\text{cm}} = \frac{m_1y_1 + m_2y_2 + m_3y_3 + \cdots + m_ny_n}{m_1 + m_2 + m_3 + \cdots + m_n} \qquad \text{Eq. (8.4)}$$

An external force pointing directly toward or away from the center of mass of a free object will not cause the object to turn or rotate. (Sections 8.1 and 8.4)





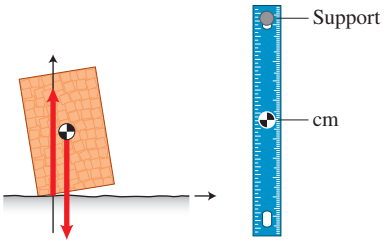
A **torque** τ around an *axis of rotation* is a physical quantity characterizing the turning ability of a force with respect to a particular axis of rotation. The torque is positive if the force tends to turn the object counterclockwise and negative if it tends to turn the object clockwise about the axis of rotation. (Section 8.2)

$$\tau = \pm Fl \sin\theta \qquad \text{Eq. (8.1)}$$

Static equilibrium is a state in which a rigid body is at rest and remains at rest both translationally and rotationally. (Section 8.3)

Translational (force) condition:

$$\Sigma F_{\text{on O}\,x} = F_{1\text{ on O}\,x} + \cdots + F_{n\text{ on O}\,x} = 0 \qquad \text{Eq. (8.2}x\text{)}$$



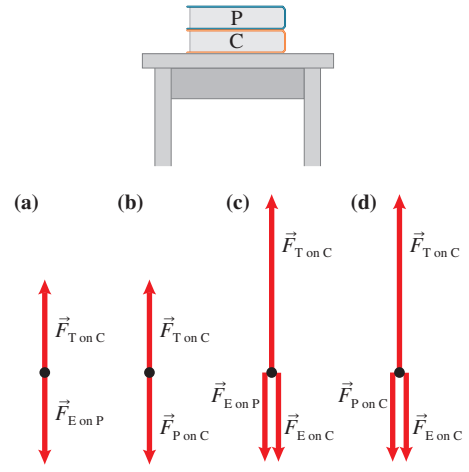
$$\Sigma F_{\text{on O}\,y} = F_{1\text{ on O}\,y} + \cdots + F_{n\text{ on O}\,y} = 0 \qquad \text{Eq. (8.2}y\text{)}$$

Rotational (torque) condition:

$$\Sigma\tau = \tau_1 + \tau_2 + \cdots + \tau_n = 0 \qquad \text{Eq. (8.3)}$$

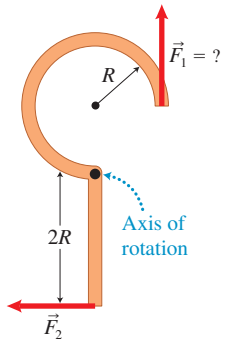
The **equilibrium** of a system is stable against tipping as long as the line through its center of mass passes through the system's area of support.

The **equilibrium** of a system is stable against rotating as long as the center of mass of the rotating object is below the axis of rotation. (Section 8.6)



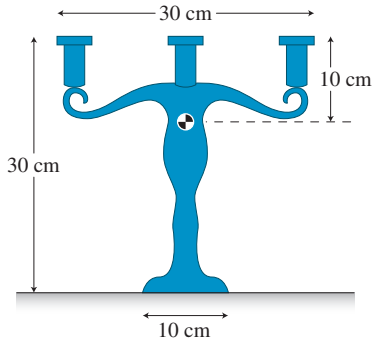
Questions

Multiple Choice Questions



1. A falling leaf usually flutters while falling. However, we have learned that the force that Earth exerts on an object is exerted at its center of mass and thus should not cause rotational motion. How can you resolve this contradiction?
   (a) A leaf is not a rigid body and the rule does not apply.
   (b) There are other forces exerted on the leaf as it falls besides the force exerted by Earth.
   (c) Some forces were not taken into account when we defined the center of mass.
2. You have an irregularly shaped flat object. To find its center of mass you can do which of the following?
   (a) Find a point where you can put a fulcrum to balance it.
   (b) Push the object in different directions and find the point of intersection of the lines of action of the forces that do not rotate the object.
   (c) Separate the object into several regularly shaped objects whose center of masses you know, and use the mathematical definition of the center of mass to find it.
   (d) All of the above
   (e) a and b only
3. A hammock is tied with ropes between two trees. A person lies in it. Under what circumstances are its ropes more likely to break?
   (a) If stretched tightly between the trees
   (b) If stretched loosely between the trees
   (c) The ropes always have equal likelihood to break.
4. Where is the center of mass of a donut?
   (a) In the center of the hole
   (b) Uniformly distributed throughout the donut
   (c) Cannot be found
5. A physics textbook lies on top of a chemistry book, which rests on a table. Which force diagram below best describes the forces exerted by other objects on the chemistry book (**Figure Q8.5**)?

FIGURE Q8.5



6. What does it mean if the torque of a force is positive?
   (a) The object exerting the force is on the right side of the axis of rotation.
   (b) The object exerting the force is on the left side of the axis of rotation.
   (c) The force points up.
   (d) The force points down.
   (e) None of these choices is necessarily correct.
7. Constant force $\vec{F}_2$ is exerted on the lower arm of the object in **Figure Q8.7**. What is the magnitude of the force $\vec{F}_1$ such that the object is in equilibrium?

FIGURE Q8.7

   (a) $F_1 = F_2$
   (b) $F_1 = \sqrt{2}F_2$
   (c) $F_1 = \frac{\pi}{2}F_2$
   (d) $F_1 = 2F_2$
   (e) $F_1 = 0$
   (f) The object cannot be in equilibrium no matter how large the force F_1 is.
8. Why do you tilt your body forward when hiking with a heavy backpack?
   (a) The backpack pushes you down.
   (b) Bending forward makes the backpack press less on your back.
   (c) Bending forward moves the center of mass of you and the backpack above your feet.
9. What does it mean if the torque of a 10-N force is zero?
   (a) The force is exerted at the axis of rotation.
   (b) A line parallel to and passing through the place where the force is exerted passes through the axis of rotation.
   (c) Both a and b are correct.
10. What is the maximum angle to the horizontal you can tilt the candleholder in **Figure Q8.10** before it tips over? The center of mass of the candleholder is marked on the figure.

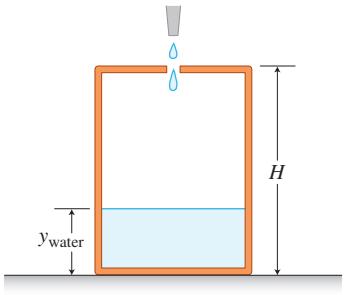


FIGURE Q8.10

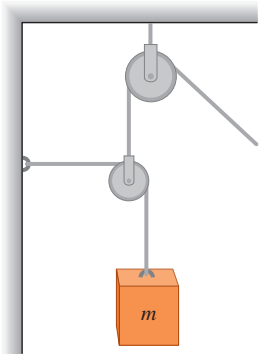
   (a) 26.6°
   (b) 18.4°
   (c) 14.0°
   (d) 9.4°
   (e) None of the above

11. Water starts dripping at a constant rate into an empty plastic can through a small opening at the top, as shown in **Figure Q8.11**. Which graph shows the correct qualitative dependence of the vertical position of the center of mass of the water-can system (y_{cm}) on the height of the water level in the can (y_{water})?

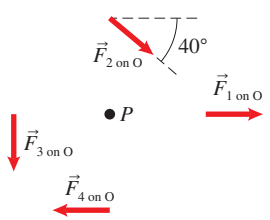
FIGURE Q8.11



Conceptual Questions

12. Is it possible for an object not to be in equilibrium when the net force exerted on it by other objects is zero? Give an example.
13. Explain the meaning of torque so that a friend not taking physics can understand.
14. Something is wrong with the orientation of the ropes shown in **Figure Q8.14**. Use the first condition of equilibrium for the hanging pulley to help explain this error, and then redraw the sketch as you would expect to see it.
15. What are the two conditions of equilibrium? What happens if one or the other condition is not satisfied?
16. Give three examples of situations in which an object is starting to rotate even though the sum of the forces exerted on the object is zero.
17. The force that the body muscles exert on bones that are used to lift various objects is usually five to ten times greater than the gravitational force that Earth exerts on the object being lifted. Explain and give an example.
18. A ladder leans against a wall. Construct a force diagram showing the direction of all forces exerted on the ladder. Identify two interacting objects for each force.
19. Using a crowbar, a person can remove a nail by exerting little force, whereas pulling directly on the nail requires a large force to remove it (you probably can't). Why? Draw a sketch to support your answer.
20. Is it more difficult to do a sit-up with your hands stretched in front of you or with them behind your head? Explain.
21. Sit on a chair with your feet straight down at the front of the chair. Keeping your back perpendicular to the floor, try to stand up without leaning forward. Explain why it is impossible to do it.
22. Can you balance the tip of a wooden ruler vertically on a fingertip? Why is it so difficult? Design a method to balance the ruler on your fingertip. Describe any extra material(s) you will use.
23. Try to balance a sharp wooden pencil on your fingertip, point down. (Hint: A small pocketknife might help by lowering the center of mass of the system.)
24. Design a device that you can use to successfully walk on a tightrope.
25. Explain why it is easier to keep your balance while jumping on two feet than while hopping on one.
26. A carpenter's trick to keep nails from bending when they are pounded into a hard material is to grip the center of the nail with pliers. Why does this help?

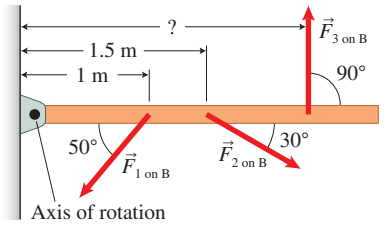
FIGURE Q8.14



Problems

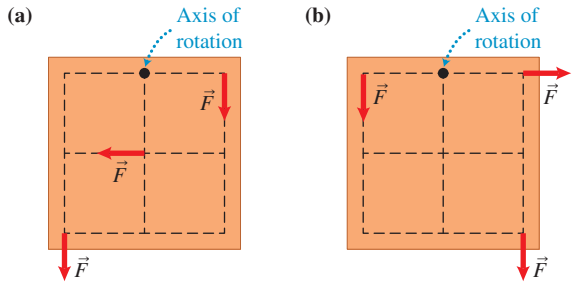
Below, BIO indicates a problem with a biological or medical focus. Problems labeled EST ask you to estimate the answer to a quantitative problem rather than derive a specific answer. Asterisks indicate the level of difficulty of the problem. Problems with no * are considered to be the least difficult. A single * marks moderately difficult problems. Two ** indicate more difficult problems.

8.2 Torque: a new physical quantity



1. Determine the torques about the axis of rotation *P* produced by each of the four forces shown in **Figure P8.1**. All forces have magnitudes of 120 N and are exerted a distance of 2.0 m from *P* on some unshown object O.

FIGURE P8.1



2. Three 200-N forces are exerted on the beam shown in **Figure P8.2**. (a) Determine the torques about the axis of rotation on the left produced by forces $\vec{F}_{1\text{ on B}}$ and $\vec{F}_{2\text{ on B}}$. (b) At what distance from the axis of rotation must $\vec{F}_{3\text{ on B}}$ be exerted to cause a torque that balances those produced by $\vec{F}_{1\text{ on B}}$ and $\vec{F}_{2\text{ on B}}$?

FIGURE P8.2

3. * A 2.0-m-long, 15-kg ladder is resting against a house wall, making a 30° angle with the vertical wall. The coefficient of static friction between the ladder feet and the ground is 0.40, and between the top of the ladder and the wall the coefficient is 0. Make a list of the physical quantities you can determine or estimate using this information and calculate them.
4. **Figure P8.4** shows two different situations where three forces of equal magnitude are exerted on a square board hanging on a wall, supported by a nail. For each case, determine the sign of the total torque that the three forces exert on the board.

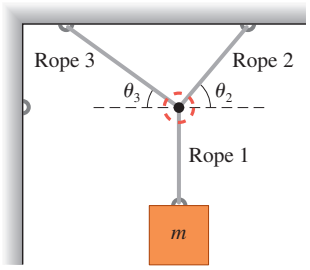


FIGURE P8.4

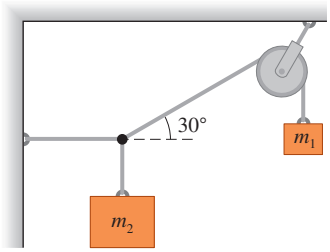
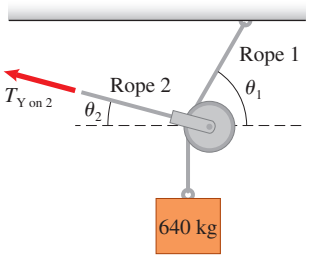
8.3 Conditions of equilibrium



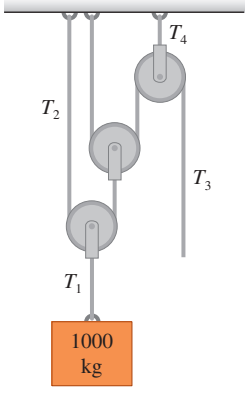
5. Three friends tie three ropes in a knot and pull on the ropes in different directions. Adrienne (rope 1) exerts a 20-N force in the positive x-direction, and Jim (rope 2) exerts a 40-N force at an angle 53° above the negative x-axis. Luis (rope 3) exerts a force that balances the first two so that the knot does not move. (a) Construct a force diagram for the knot. (b) Use equilibrium conditions to write equations that can be used to determine $F_{\text{L on K}\,x}$ and $F_{\text{L on K}\,y}$. (c) Use equilibrium conditions to write equations that can be used to determine the magnitude and direction of $\vec{F}_{\text{L on K}}$.
6. Adrienne from Problem 8.5 now exerts a 100-N force $\vec{F}_{\text{A on K}}$ that points 30° below the positive x-axis, and Jim exerts a 150-N force in the negative y-direction. How hard and in what direction does Luis now have to pull the knot so that it remains in equilibrium?
7. * Kate joins Jim, Luis, and Adrienne in the rope-pulling exercise described in the previous two problems. This time, they tie four ropes to a ring. The three friends each pull on one rope, exerting the following forces: $\vec{T}_{1\text{ on R}}$ (50 N in the positive y-direction), $\vec{T}_{2\text{ on R}}$ (20 N, 25° above the negative x-axis), and $\vec{T}_{3\text{ on R}}$ (70 N, 70° below the negative x-axis). Kate pulls rope 4, exerting a force $\vec{T}_{4\text{ on R}}$ so that the ring remains in equilibrium. (a) Construct a force diagram for the ring. (b) Use the first condition of equilibrium to write two equations that can be used to determine $T_{4\text{ on R}\,x}$ and $T_{4\text{ on R}\,y}$. (c) Solve these equations and determine the magnitude and direction of $\vec{T}_{4\text{ on R}}$.
8. You hang a light in front of your house using an elaborate system to keep the 1.2-kg light in static equilibrium (see **Figure P8.8**). What are the magnitudes of the forces that the ropes must exert on the knot connecting the three ropes if $\theta_2 = 37°$ and $\theta_3 = 0°$? Rope 3 can be tied to the hook on the wall.

FIGURE P8.8



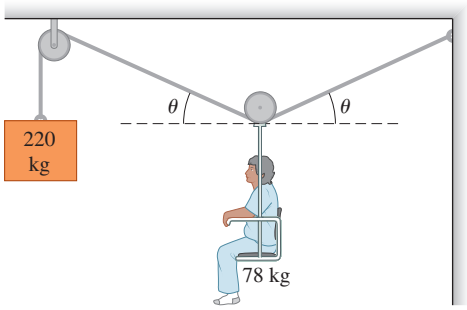
9. * Find the values of the forces the ropes exert on the knot if you replace the light in Problem 8.8 with a heavier 12-kg object and the ropes make angles of $\theta_2 = 63°$ and $\theta_3 = 45°$ (see Figure P8.8).
10. Redraw Figure P8.8 with $\theta_2 = 50°$ and $\theta_3 = 0°$. Rope 2 is found to exert a 100-N force on the knot. Determine m and the magnitudes of the forces that the other two ropes exert on the knot.
11. Determine the masses m_1 and m_2 of the two objects shown in **Figure P8.11** if the force exerted by the horizontal cable on the knot is 64 N.

FIGURE P8.11



12. * **Lifting an engine** You work in a machine shop and need to move a huge 640-kg engine up and to the left in order to slide a cart under it. You use the system shown in **Figure P8.12**. How hard and in what direction do you need to pull on rope 2 if the angle between rope 1 and the horizontal is $\theta_1 = 60°$?

FIGURE P8.12

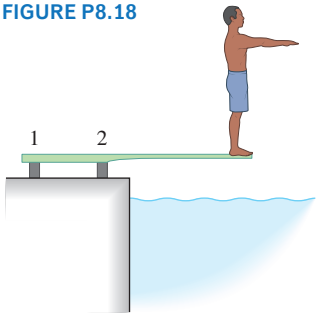


13. * **More lifting** You exert a 630-N force on rope 2 in the previous problem (Figure P8.12). Write the two equations (x and y) for the first condition of equilibrium using the pulley as the object of interest for a force diagram. Calculate θ_1 and θ_2. You may need to use the identity $(\sin\theta)^2 + (\cos\theta)^2 = 1$.
14. **Even more lifting** A pulley system shown in **Figure P8.14** will allow you to lift heavy objects in the machine shop by exerting a relatively small force. (a) Construct a force diagram for each pulley. (b) Use the equations of equilibrium and the force diagrams to determine T_1, T_2, T_3, and T_4.

FIGURE P8.14

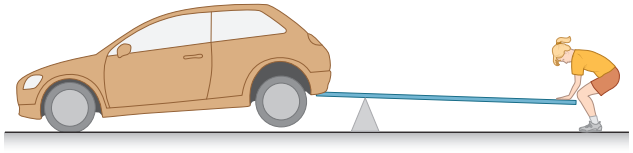
15. * **Tightrope walking** A tightrope walker wonders if her rope is safe. Her mass is 60 kg and the length of the rope is about 20 m. The rope will break if its tension exceeds 6700 N. What is the smallest angle at which the rope can bend up from the horizontal on either side of her to avoid breaking?
16. * **Lifting patients** An apparatus to lift hospital patients sitting at the sides of their beds is shown in **Figure P8.16**. At what angle above the horizontal does the rope going under the pulley bend while supporting the 78-kg person hanging from the pulley?

FIGURE P8.16



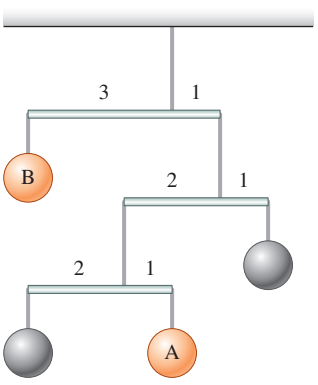
17. A father (80 kg), mother (56 kg), daughter (16 kg), and son (24 kg) try to occupy seats on the seesaw shown in **Figure P8.17** so that the seesaw is in equilibrium. Can they succeed? Explain.

FIGURE P8.17



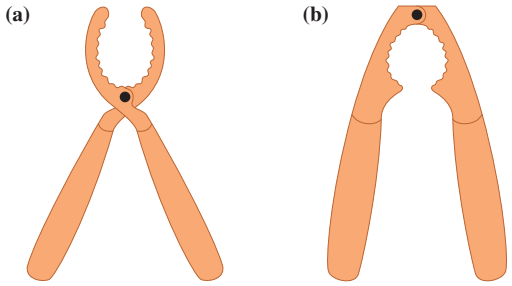
18. * You stand at the end of a uniform diving board a distance d from support 2 (similar to that shown in **Figure P8.18**). Your mass is m , and the distance between the two supports is a. What can you determine from this information? Make a list of physical quantities and show how you will determine them.

FIGURE P8.18



19. * You place a 3.0-m-long board symmetrically across a 0.5-m-wide chair to seat three physics students at a party at your house. If 70-kg Dan sits on the left end of the board and 50-kg Tahreen sits on the right end of the board, where should 54-kg Komila sit to keep the board stable? What assumptions did you make?
20. **Car jack** You've got a flat tire. To lift your car, you make a homemade lever (see **Figure P8.20**). A very light 1.6-m-long handle part is pushed down on the right side of the fulcrum and a 0.10-m-long part on the left side supports the back of the car. How hard must you push down on the handle so that the lever exerts an 8000-N force to lift the back of the car?

FIGURE P8.20

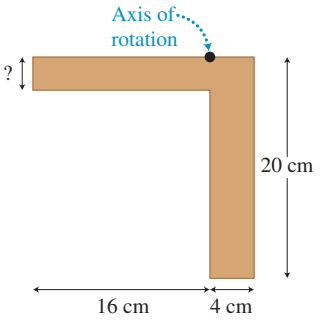


21. * **Mobile** You are building a toy mobile, copying the design shown in **Figure P8.21**. Object A has a 1.0-kg mass. What should be the mass of object B? The numbers in Figure P8.21 indicate the relative lengths of the rods on each side of their supporting cords.

FIGURE P8.21

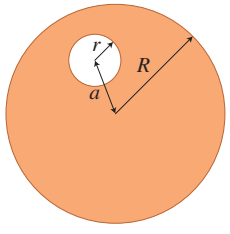
22. **Another mobile** You are building a toy mobile similar to that shown in Figure P8.21 but with different dimensions and replacing the objects with cups. The bottom rod is 20 cm long, the middle rod is 15 cm long, and the top rod is 8 cm long. You put one penny in the bottom left cup, three pennies in the bottom right cup, eleven pennies in the middle right cup, and five pennies in the top left cup. (a) Draw a force diagram for each rod. (b) Determine the cord attachment points and lengths on each side for each rod. (c) What assumptions did you make in order to solve the problem?
23. **EST** Compare the two different designs of nutcracker shown in **Figure P8.23** and decide which one is more efficient in cracking a nut. Estimate the forces exerted by each cracker on the nut when a 30-N force is exerted on each handle. Indicate any assumptions that you made. You will need a ruler to solve this problem.

FIGURE P8.23



24. Ray decides to paint the outside of his uncle's house. He uses a 4.0-m-long board supported by vertical cables at each end to paint the second floor. The board has a mass of 21 kg. Ray (70 kg) stands 1.0 m from the left cable. What are the forces that each cable exerts on the board?
25. * A 2.0-m-long uniform beam of mass 8.0 kg supports a 12.0-kg bag of vegetables at one end and a 6.0-kg bag of fruit at the other end. At what distance from the vegetables should the beam rest on your shoulder to balance? What assumptions did you make?
26. * A uniform beam of length l and mass m supports a bag of mass m_1 at the left end, another bag of mass m_2 at the right end, and a third bag m_3 at a distance l_3 from the left end ($l_3 < 0.5l$). At what distance from the left end should you support the beam so that it balances?

8.4 Center of mass

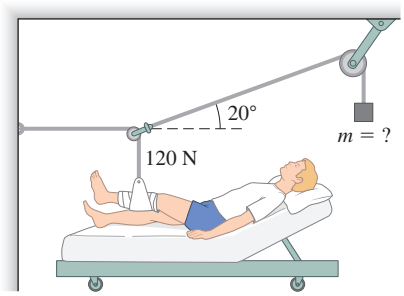


27. A person whose height is 1.88 m is lying on a light board placed on two scales so that scale 1 is under the person's head and scale 2 is under the person's feet. Scale 1 reads 48.3 kg and scale 2 reads 39.3 kg. Where is the center of mass of the person?
28. * A seesaw has a mass of 30 kg, a length of 3.0 m, and a fulcrum beneath its midpoint. It is balanced when a 60-kg person sits on one end and a 75-kg person sits on the other end. Locate the center of mass of the seesaw. Where is the center of mass of a uniform seesaw that is 3.0 m long and has a mass of 30 kg if two people of masses 60 kg and 75 kg sit on its ends?
29. * You decide to cut an L-shaped object out of cardboard so that the object is in static equilibrium if hung as shown in **Figure P8.29**. Find the missing dimension of the object. Cut the object out of some cardboard and check if your result is correct.

FIGURE P8.29

30. * You have a 1-m-wide, 2-m-long 14-kg wooden board. If you place a 5.0-kg pot of soup in one corner of the board, where is the center of mass of the board-pot system?
31. * An 80-kg clown sits on a 20-kg bike on a tightrope attached between two trees. The center of mass of the clown is 1.6 m above the rope, and the center of mass of the bike is 0.7 m above the rope. A load of what mass should be fixed onto the bike and hang 1.5 m below the rope so that the center of mass of the clown-bike-load system is 0.5 m below the rope? What is the force that the rope exerts on each tree if the angle between the rope and the horizontal is 10°?

FIGURE P8.32



32. ** **Figure P8.32** shows a disk of radius R with a circular hole of radius r cut a distance a from the center of the disk. Where is the disk's center of mass? (Hint: You can think of cutting the hole as adding material of negative mass to the original object.)

8.5 Skills for analyzing situations using equilibrium conditions

33. **Leg support** A person's broken leg is kept in place by the apparatus shown in Figure P8.33. If the rope pulling on the leg exerts a 120-N force on it, how massive should be the block hanging from the rope that passes over the pulley? First, derive a general expression for m in terms of relevant parameters and then determine the mass of the block.

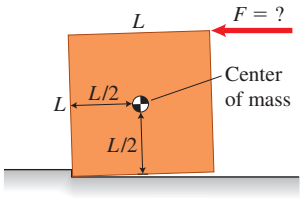


FIGURE P8.33

34. * **Diving board** The diving board shown in Figure P8.18 has a mass of 28 kg and its center of mass is at the board's geometrical center. Determine the forces that support posts 1 and 2 (separated by 1.4 m) exert on the board when a 60-kg person stands on the end of the board 2.8 m from support post 2.

35. ** A uniform cubical box of mass m and side L sits on the floor with its bottom left edge pressing against a ridge. Derive the expression for the least force you need to exert horizontally at the top right edge of the box that will cause its bottom right edge to be slightly off the floor, as shown in Figure P8.35. (Note: With the right edge slightly off the floor, the ground and ridge exert their forces on the bottom left edge of the box.)

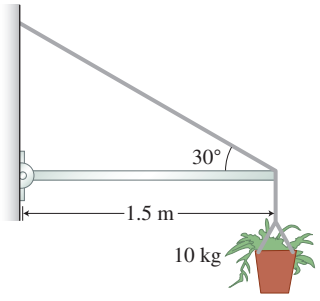

FIGURE P8.35

36. * If the force F shown in Figure P8.35 is 840 N and the bottom right edge of the box is slightly off the ground, what is the mass of the cubical box of side 1.2 m?

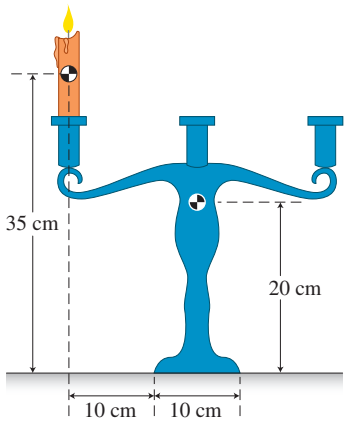
37. * You decide to hang a new 10-kg flowerpot using the arrangement shown in Figure P8.37. Can you use a slanted rope attached from the wall to the end of the beam if that rope breaks when the tension exceeds 170 N? The mass of the beam is not known, but it looks light.

FIGURE P8.37

38. * You decide to hang another plant from a 1.5-m-long 2.0-kg horizontal beam that is attached by a hinge to the wall on the left. A cable attached to the right end goes 37° above the beam to a connecting point above the hinge on the wall. You hang a 100-N pot from the beam 1.4 m away from the wall. What is the force that the cable exerts on the beam?

39. * Now you decide to change the way you hang the pot described in Problems 8.37 and 8.38. You orient the beam at a 37° angle above the horizontal and orient the cable horizontally from the wall to the end of the beam. The beam still holds the 2.0-kg pot and plant hanging 0.1 m from its end. Now determine the force that the cable exerts on the beam and the force that the wall hinge exerts on the beam (its x- and y-components and the magnitude and direction of that force).

40. * What mechanical work must you do to lift a log that is 3.0 m long and has a mass of 100 kg from the horizontal to a vertical position? (Hint: Use the work-energy principle.) You are lifting one end of the log while the other end is on the ground all the time.



8.6 Stability of equilibrium

41. * A 70-g meter stick has a 30-g piece of modeling clay attached to the end. Where should you drill a hole in the meter stick so that you can hang the stick horizontally in equilibrium on a nail in the wall? Draw a picture to help explain your decision.

42. * You are trying to tilt a very tall refrigerator (2.0 m high, 1.0 m deep, 1.4 m wide, and 100 kg) so that your friend can put a blanket underneath to slide it out of the kitchen. Determine the force that you need to exert on the front of the refrigerator at the start of its tipping. You push horizontally 1.4 m above the floor.

43. Can you put a 0.2-kg candle on a 0.6-kg candleholder, as shown in Figure P8.43, without tipping the candleholder over? Explain. The centers of mass of the candle and candleholder are marked on the figure.

FIGURE P8.43

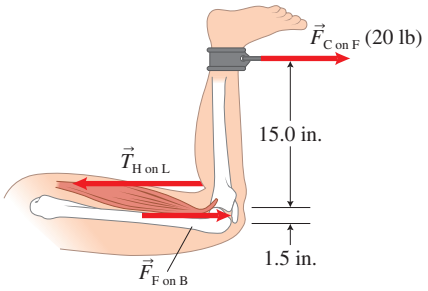
44. * You have an Atwood machine (see Figure 4.9) with two blocks each of mass m attached to the ends of a string of length l. The string passes over a frictionless pulley down to the blocks hanging on each side. While pulling down on one block, you release it. Both blocks continue to move at constant speed, one up and the other down. Is the system still in equilibrium? Find the vertical component of the center of mass of the two-block system. Indicate all of your assumptions and the coordinate system used.

45. * EST You stand sideways in a moving train. Estimate how far apart you should keep your feet so that when the train accelerates at 2.0 m/s^2 you can still stand without holding anything. List all your assumptions.

General Problems

46. EST Your hand holds a liter of milk (mass about 1 kg) while your arm is bent at the elbow in a 90° angle. Estimate the torque caused by the milk on your arm about the elbow joint. Indicate all numbers used in your calculations. This is an estimate, and your answer may differ by 10 to 50% from the answers of others.

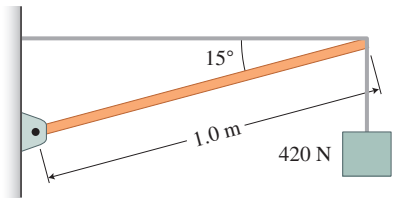
47. EST **Body torque** You hold a 4.0-kg computer. Estimate the torques exerted on your forearm about the elbow joint caused by the downward force exerted by the computer on the forearm and the upward 340-N force exerted by the biceps muscle on the forearm. Ignore the mass of the arm. Indicate any assumptions you make.



48. * **Using biceps to hold a child** A man is holding a 16-kg child using both hands with his elbows bent in a 90° angle. The biceps muscle provides the positive torque he needs to support the child. Determine the force that each of his biceps muscles must exert on the forearm in order to hold the child safely in this position. Ignore the triceps muscle and the mass of the arm.

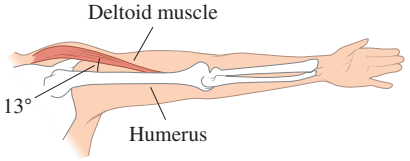
49. BIO **Using triceps to push a table** A man pushes on a table exerting a 20-N downward force with his hand. Determine the force that his triceps muscle must exert on his forearm in order to balance the upward force that the table exerts on his hand. Ignore the biceps muscle and the mass of the arm. If you did not ignore the mass of the arm, would the force you determined be smaller or larger? Explain.

50. * BIO **Using biceps to hold a dumbbell** Find the force that the biceps muscle shown in Example 8.5 exerts on the forearm when you lift a 16-kg dumbbell with your hand. Also determine the force that the bone in the upper arm (the humerus) exerts on the bone in the forearm at the elbow joint. The mass of the forearm is about 5.0 kg and its center of mass is 16 cm from the elbow joint. Ignore the triceps muscle.



51. * BIO **Hamstring** You are exercising your hamstring muscle (the large muscle in the back of the thigh). You use an elastic cord attached to a hook on the wall while keeping your leg in a bent position (**Figure P8.51**). Determine the magnitude of the tension force $\vec{T}_{\text{H on L}}$ exerted by the hamstring muscles on the leg and the magnitude of compression force $\vec{F}_{\text{F on B}}$ at the knee joint that the femur exerts on the calf bone. The cord exerts a 20-lb force $\vec{F}_{\text{C on F}}$ on the foot.

FIGURE P8.51



52. * BIO **Lift with bent legs** You injure your back at work lifting a 420-N radiator. To understand how it happened, you model your back as a weightless beam (**Figure P8.52**), analogous to the backbone of a person in a bent position when lifting an object. (a) Determine the tension force that the horizontal cable exerts on the beam (which is analogous to the force the back muscle exerts on the backbone) and the force that the wall exerts on the beam at the hinge (which is analogous to the force that a disk in the lower back exerts on the backbone). (b) Why do doctors recommend lifting objects with the legs bent?

FIGURE P8.52

53. * BIO **Dumbbell lift I** A woman lifts a 3.6-kg dumbbell in each hand with her arm in a horizontal position at the side of her body and holds it there for 3 s (see **Figure P8.53**). What force does the deltoid muscle in her shoulder exert on the humerus bone while holding the dumbbell? The deltoid attaches 13 cm from the shoulder joint and makes a 13° angle with the humerus. The dumbbell in her hand is 0.55 m from the shoulder joint, and the center of mass of her 4.0-kg arm is 0.24 m from the joint.

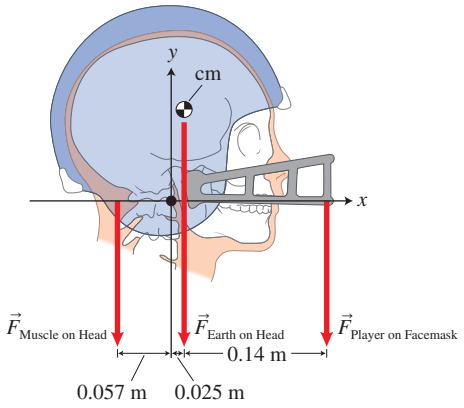


FIGURE P8.53

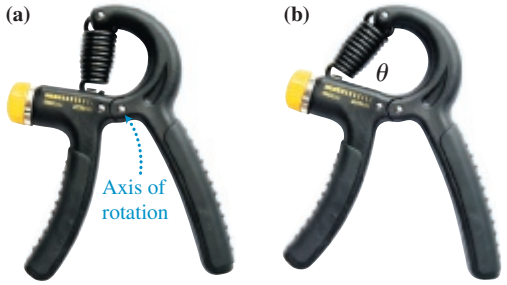
54. ** BIO **Dumbbell lift II** Repeat the previous problem with a 7.2-kg dumbbell. Determine both the force that the deltoid exerts on the humerus and the force that the lifter's shoulder joint exerts on her humerus.

55. * BIO **Facemask penalty** The head of a football running back (see **Figure P8.55**) can be considered as a lever with the vertebra at the bottom of the skull as a fulcrum (the axis of rotation). The center of mass is about 0.025 m in front of the axis of rotation. The torque caused by the force that Earth exerts on the 8.0-kg head/helmet is balanced by the torque caused by the downward forces exerted by a complex muscle system in the neck. That muscle system includes the trapezius and levator scapulae muscles, among others (effectively 0.057 m from the axis of rotation). (a) Determine the magnitude of the force exerted by the neck muscle system pulling down to balance the torque caused by the force exerted by Earth on the head. (b) If an opposing player exerts a downward 180-N (40-lb) force on the facemask, what muscle force would these neck muscles now need to exert to keep the head in equilibrium?

FIGURE P8.55

56. * Eiichi has purchased an adjustable hand grip to use for strengthening hands, fingers, and wrists. The hand grip consists of two handles that can rotate around a common axis and a spring that connects the handles (see **Figure P8.56**). The force needed to squeeze the hand grip can be adjusted from small (Figure P8.56a) to large (Figure P8.56b) by changing the position at which the lower end of the spring is hooked to the left handle. Eiichi, Yuko, and Lars have different explanations for why it is harder to squeeze the hand grip in case (b) compared to (a).



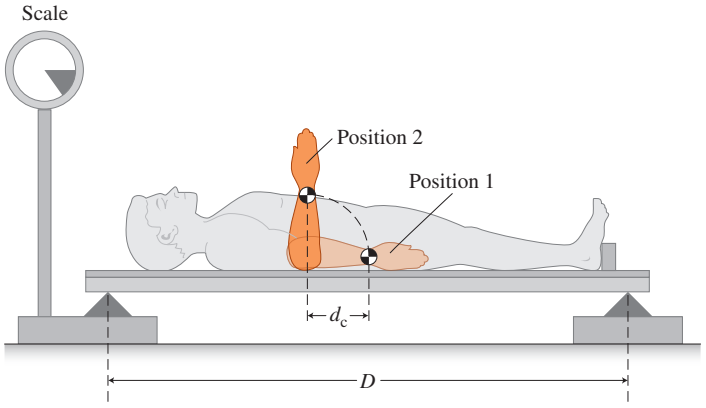
Eiichi: It is harder to squeeze the hand grip because the distance between the axis of rotation and the point where the force is exerted on the left handle by the spring is larger in case (b) than in case (a).

Yuko: It is harder to squeeze the hand grip because the extension of the spring in case (b) is larger than in case (a).

Lars: It is harder to squeeze the hand grip because the angle θ in case (b) is smaller than in case (a).

First, comment on the students' explanations and decide whose ideas are correct and whose aren't. Then construct a complete correct explanation. Indicate any assumptions that you made.

FIGURE P8.56



57. * BIO While browsing books on neurophysiology, you come across a book published in 1967 by Soviet neurophysiologist Nikolai Aleksandrovich Bernstein, *The Co-ordination and Regulation of Movements*, in which he describes a technique to determine the mass of a part of the human body if the position of the center of mass of that body part is known. His technique for determining the mass of the forearm is described as follows: The person lies on a support board, as shown in **Figure P8.57**. Two readings of the scale are taken: first with the forearm held in position 1 (m_1) and second with it in position 2 (m_2). Knowing the distance from the elbow to the center of mass of the forearm (d_c) and the distance between the knife edges supporting the board (D), the mass of the forearm and hand can be calculated from the following expression:

$$m_{fh} = \frac{D(m_2 - m_1)}{d_c}$$

(a) First, without deriving the expression, evaluate it to see if it is reasonable. Are the units correct? Is the sign of the expression positive? Are qualitative dependences reasonable? (b) Now derive the expression. (c) Why do you think it is important to place the support board on knife edges instead of rigid blocks?

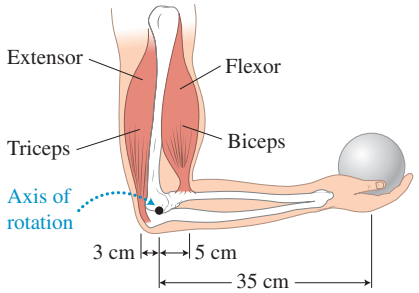
FIGURE P8.57

58. ** **Touch detector** You have two force sensors connected to a computer and a meter stick of known mass. The sensors are used to keep the stick horizontal; there are no other supports. You push on the stick with your finger in an arbitrary location. (a) Design an experimental setup that will allow you to determine the magnitude of your pushing force F and the location of your finger x based on the readings of the two force sensors. (b) Derive an expression that can be used as a computer algorithm to calculate x and F using the readings of the force sensors and the parameters of your setup. (c) Evaluate the expression, analyzing the limiting cases.

59. ** Design two experiments to determine the mass of a ruler, using different methods. Your available materials are the ruler, a spring, and a set of objects of standard mass: 50 g, 100 g, and 200 g. One of the methods should involve your knowledge of static equilibrium. After you design and perform the experiment, decide whether the two methods give you the same or different results.

60. * An 80-kg person stands at one end of a 130-kg boat. He then walks to the other end of the boat so that the boat moves 80 cm with respect to the bottom of the lake. (a) What is the length of the boat? (b) How much did the center of mass of the person-boat system move when the person walked from one end to the other? (Hint: Note that the total momentum of the person-boat system remains constant.)

61. EST Two people (50 kg and 75 kg) holding hands stand on Rollerblades 1.0 m apart. (a) Estimate the location of their center of mass. (b) The two people push each other and roll apart. Estimate the new location of the center of mass when they are 4.0 m apart. What assumptions did you make? (Hint: Note that the total momentum of the two people remains constant.)



62. ** Find the center of mass of an L-shaped object. The vertical leg has a mass of m_a of length a and the horizontal leg has a mass of m_b of length b. Both legs have the same width w, which is much smaller than a or b.

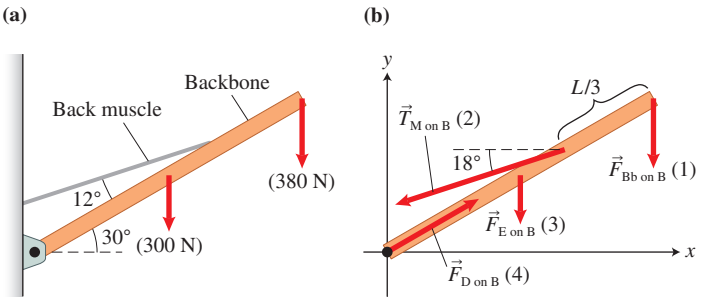
Reading Passage Problems

BIO **Muscles work in pairs** Skeletal muscles produce movements by pulling on tendons, which in turn pull on bones. Usually, a muscle is attached to two bones via a tendon on each end of the muscle. When the muscle contracts, it moves one bone toward the other. The other bone remains in nearly the original position. The point where a muscle tendon is attached to the stationary bone is called the *origin*. The point where the other muscle tendon is attached to the movable bone is called the *insertion*. The origin is like the part of a door spring that is attached to the doorframe. The insertion is similar to the part of the spring that is attached to the movable door.

During movement, bones act as levers and joints act as axes of rotation for these levers. Most movements require several skeletal muscles working in groups, because a muscle can only exert a pull and not a push. In addition, most skeletal muscles are arranged in opposing pairs at joints. Muscles that bring two limbs together are called flexor muscles (such as the biceps muscle in the upper arm in **Figure 8.25**). Those that cause the limb to extend outward are called extensor muscles (such as the triceps muscle in the upper arm). The flexor muscle is used when you hold a heavy object in your hand; the extensor muscle can be used, for example, to extend your arm when you throw a ball.

FIGURE 8.25 Muscles often come in flexor-extensor pairs.

63. You hold a 10-lb ball in your hand with your forearm horizontal, forming a 90° angle with the upper arm (Figure 8.25). Which type of muscle produces the torque that allows you to hold the ball?
(a) Flexor muscle in the upper arm
(b) Extensor muscle in the upper arm
(c) Flexor muscle in the forearm
(d) Extensor muscle in the forearm



64. In Figure 8.25, how far in centimeters from the axis of rotation are the forces that the ball exerts on the hand, that the biceps exerts on your forearm, and that the upper arm exerts on your forearm at the elbow joint?
(a) 0, 5, 35 (b) 35, 5, 0 (c) 35, 5, 3
(d) 35, 5, −3 (e) 30, 5, 0

65. Why is it easier to hold a heavy object using a bent arm than a straight arm?
(a) More flexor muscles are involved.
(b) The distance from the joint to the place where gravitational force is exerted by Earth on the object is smaller.
(c) The distance from the joint to the place where force is exerted by the object on the hand is smaller.
(d) There are two possible axes of rotation instead of one.

66. Why are muscles arranged in pairs at joints?
(a) Two muscles can produce a bigger torque than one.
(b) One can produce a positive torque and the other a negative torque.
(c) One muscle can pull on the bone and the other can push.
(d) Both a and b are true.

BIO Improper lifting and the back A careful study of human anatomy allows medical researchers to use the conditions of equilibrium to estimate the internal forces that body parts exert on each other while a person lifts in a bent position (see Figure 8.19). Suppose an 800-N (180-lb) person lifts a 220-N (50-lb) barbell in a bent position. The situation can be represented with a mechanical model (**Figure 8.26a**). The cable (the back muscle) exerts a tension force $\vec{T}_{\text{M on B}}$ on the backbone and the support at the bottom of the beam (the disk in the lower back) exerts a compression force $\vec{F}_{\text{D on B}}$ on the backbone. The backbone in turn exerts the same magnitude force on the 2.5-cm-diameter fluid-filled disks in the lower backbone. Such disk compression can cause serious back problems. A force diagram of this situation is shown in Figure 8.26b. The magnitude of the gravitational force $\vec{F}_{\text{E on B}}$ that Earth exerts on the center of mass of the upper stomach-chest region is 300 N. Earth exerts a 380-N force on the head, arms, and 220-N barbell held in the hands. Using the conditions of equilibrium, we estimate that the back muscle exerts a 3400-N (760-lb) force $\vec{T}_{\text{M on B}}$ on the backbone and that the disk in the lower back exerts a 3700-N (830-lb) force $\vec{F}_{\text{D on B}}$ on the backbone. This is like supporting a grand piano on the 2.5-cm-diameter disk.

FIGURE 8.26 Analysis of a person's backbone when lifting from a bent position.

67. Rank in order the magnitudes of the torques caused by the four forces exerted on the backbone (see Figure 8.26b), with the largest torque listed first.
(a) $1 > 2 > 3 > 4$ (b) $2 = 3 > 1 > 4$
(c) $3 > 2 > 1 > 4$ (d) $2 > 1 > 3 > 4$
(e) $1 = 2 = 3 = 4$

68. What are the signs of the torques caused by forces 1, 2, 3, and 4, respectively, about the origin of the coordinate system shown in Figure 8.26b?
(a) $+, +, +, +$ (b) $-, +, -, 0$
(c) $+, -, +, 0$ (d) $-, -, -, 0$
(e) $+, -, +, -$

69. Which expression below best describes the torque caused by force $F_3 = F_{\text{E on B}}$, the force that Earth exerts on the upper body at its center of mass for the backbone of length L?
(a) 0 (b) $F_3(2L/3)\sin 12°$
(c) $F_3(L/2)\cos 30°$ (d) $-F_3(2L/3)\sin 12°$
(e) $-F_3(L/2)\cos 30°$

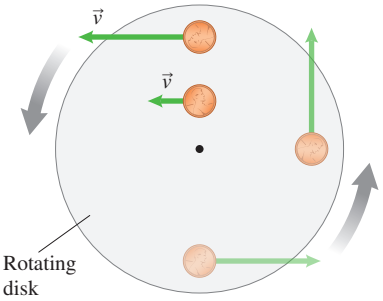
70. Which expression below best describes the torque caused by force $F_2 = T_{\text{M on B}}$ exerted by the muscle on the backbone?
(a) 0 (b) $F_2(2L/3)\sin 12°$
(c) $F_2(L)\cos 30°$ (d) $-F_2(2L/3)\sin 12°$
(e) $-F_2(L)\cos 30°$

9

Rotational Motion

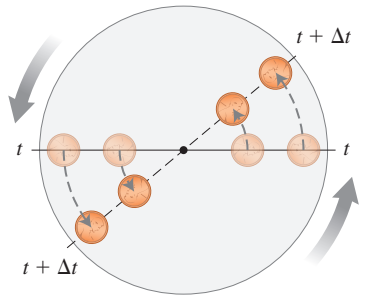
In 1967, a group of astrophysicists from the University of Cambridge in England was looking for quasars using an enormous radio telescope. Jocelyn Bell, a physics graduate student, noticed a series of regular radio pulses in the midst of a lot of receiver noise. It looked like somebody was sending a radio message, turning the signal on and off every 1.33 seconds. This is an incredibly small time for astronomical objects. At first, the astrophysicists believed that they had found signals from extraterrestrial life. The group had, in fact, discovered a new class of astronomical objects, called pulsars, which emit radio signals every second or so. The study of rotational motion explains how pulsars can emit signals so rapidly.

- **How can a star rotate 1000 times faster than a merry-go-round?**
- **Why is it more difficult to balance on a stopped bike than on a moving bike?**
- **How is the Moon slowing Earth's rate of rotation?**



IN THE LAST CHAPTER, we only analyzed rigid bodies that remained at rest. In many cases, however, objects do not remain at rest when torques are exerted—they rotate. Think about a car tire that rotates around the axle as the car moves. In this chapter, we will learn how to describe, explain, and predict such motions.

BE SURE YOU KNOW HOW TO:



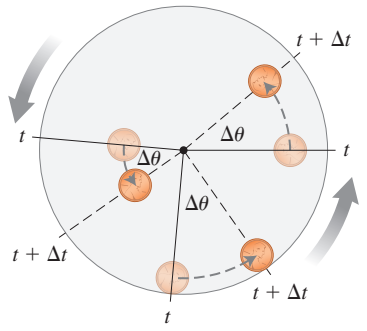
- Draw a force diagram for a system (Section 3.1).
- Determine the torque produced by a force (Section 8.2).
- Apply conditions of static equilibrium for a rigid body (Section 8.3).

FIGURE 9.1 Top views comparing the velocities of coins traveling on a rotating disk.

(a) The direction of the velocity $\vec{v}$ for each coin changes continually.

(b) Coins at the edge travel farther during Δt than those near the center. The speed v will be greater for coins near the edge than for coins near the center.

(c) All coins turn through the same angle in Δt, regardless of their position on the disk.



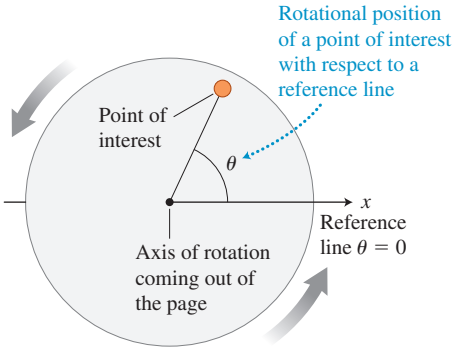


FIGURE 9.2 The rotational position of a point on a rotating disk.

9.1 Rotational kinematics

In order to understand the motion of rotating rigid bodies, we will follow the same strategy that we used for linear motion. We start by investigating how to describe rotational motion and to explain how forces and torques cause objects to rotate in the way they do. This will help us understand why a bicycle is so stable when moving, how the gravitational pull of the Moon slows the rotation of Earth, and many other interesting phenomena.

One common example of a rotating rigid body is a spinning disk, such as a turning DVD. Suppose a horizontal disk is rotating on a lab bench in front of you and you are looking down on it. You wish to describe the counterclockwise motion of the disk quantitatively. This is trickier than it might seem at first. When we investigated the motion of point-like objects, we did not have to specify which part of the object we were describing, since the object was located at a single point. With a rigid body, there are infinitely many points to choose from. For example, imagine that you place small coins at different locations on the disk, as shown in **Figure 9.1a**. As the disk turns, you observe that the direction of the velocity of each coin changes continually (see the coins on the outer edge of the disk in Figure 9.1a). In addition, a coin that sits closer to the edge moves faster and covers a longer distance during a particular time interval than a coin closer to the center (Figure 9.1b). This means that different parts of the disk move not only in different directions, but also at different speeds relative to you.

On the other hand, there are similarities between the motions of different points on a rotating rigid body. In Figure 9.1c, we see that during a particular time interval, all coins at the different points on the rotating disk turn through the same angle. Perhaps we should describe the rotational position of a rigid body using an angle.

Rotational (angular) position θ

Consider again a disk that rotates on a lab bench about a fixed point. The axis of rotation passes through the center of and is perpendicular to the disk (**Figure 9.2**). A fixed line *perpendicular* to the axis of rotation (like the positive x-axis in Figure 9.2) is used as a reference line. We can draw another line on the disk from the axis of rotation to a point of interest, for example, to a coin sitting on the rotating disk. The angle θ in the counterclockwise direction between the reference line and the line to the point of interest is the **rotational position** (or **angular position**) of the point of interest. The observer is stationary beside the lab bench and looking down on the disk.

Rotational position θ The rotational position θ of a point on a rotating object (sometimes called the angular position) is defined as an angle in the counterclockwise direction between a reference line (usually the positive x-axis) and a line drawn from the axis of rotation to that point. The units of rotational position can be either degrees or radians.

Units of rotational position

The degree (°) is the most familiar unit of rotational position. There are 360° in a circle. If a point on the turning object is at the top of the circle, its position is 90° from a horizontal, positive x-axis. When at the bottom of the circle, its position is 270° or, equivalently, −90°.

The unit for rotational position that is most useful in physics is the **radian**. It is defined in terms of the two lengths shown in **Figure 9.3**. The **arc length** s is the path length in the counterclockwise (CCW) direction along the circumference of the circle from the positive x-axis to the position of a point on the circumference of the rotating

object. The other length is the radius r of the circle. The angle θ in units of radians (rad) is the ratio of s and r:

$$\theta \text{ (in radians)} = \frac{s}{r} \tag{9.1}$$

Note that the radian unit has no dimensions; it is the ratio of two lengths. We can multiply by the radian unit or remove the radian unit from an equation with no consequence. If we put the unit **rad** in the equation, it is usually because it is a reminder that we are using radians for angles.

TIP From Eq. (9.1) we see that the arc length for a 1-rad angle equals the radius of the circle. For example, the 1-rad angle shown in **Figure 9.4** is the ratio of the 2-cm arc length and the 2-cm radius and is simply 1. If you use a calculator to work with radians, make sure it is in the radian mode.

One complete rotation around a circle corresponds to a change in arc length of $2\pi r$ (the circumference of the circle) and a change in rotational position of

$$\theta \text{ (one complete rotation)} = \frac{s}{r} = \frac{2\pi r}{r} = 2\pi$$

Thus, there are 2π radians in one circle. We can now relate the two rotational position units:

$$360^\circ = 2\pi \text{ rad}$$

We can use this equation to convert between degrees and radians.

We can use Eq. (9.1) to find the arc length s if the radius and rotational position θ are known:

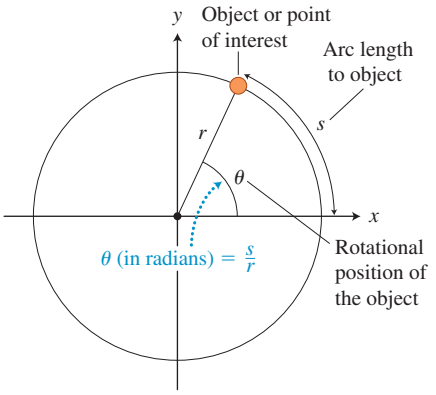
$$s = r\theta \text{ (for } \theta \text{ in radians only)}$$

For example, if a car travels 2.0 rad around a highway curve of radius 100 m, the car travels a path length along the arc equal to

$$s = r\theta = (100 \text{ m})(2.0 \text{ rad}) = 200 \text{ m}$$

We dropped the radian unit in the answer because angles measured in radians are dimensionless.

FIGURE 9.3 The rotational position θ in radians is the ratio of the arc length s and the radius r.



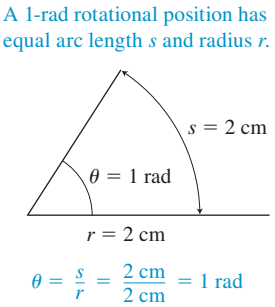


FIGURE 9.4 The arc length for a 1-rad angle equals the radius of the circle.

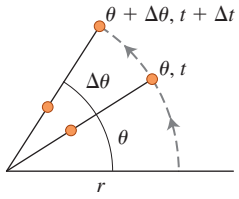
TIP You cannot calculate arc length using $s = r\theta$ when θ is measured in degrees. You must first convert θ to radians.

Rotational (angular) velocity ω



When we were investigating the motion of a point-like object along a single axis, we defined the translational velocity of that object as the rate of change of its linear position. Thus, it seems natural to define the **rotational (angular) velocity** ω of a rigid body as the rate of change of each point's rotational position. Because all points on the rigid body rotate through the same angle in the same period of time (see Figure 9.1c), each point on the rigid body has the same rotational velocity. This means we can just refer to the rotational velocity of the rigid body itself, rather than to any specific point within it.

Rotational velocity ω The average rotational velocity (sometimes called angular velocity) of a turning rigid body is the ratio of its change in rotational position $\Delta\theta$ and the time interval Δt needed for that change (see **Figure 9.5**):

$$\omega = \frac{\Delta\theta}{\Delta t} \tag{9.2}$$

The sign of ω (omega) is positive for counterclockwise turning and negative for clockwise turning, as seen looking along the axis of rotation. *Rotational (angular) speed* is the magnitude of the rotational velocity. The most common units for rotational velocity and speed are radians per second (rad/s) and revolutions per minute (rpm).

FIGURE 9.5 Each point on a rigid body has the same rotational velocity ω.

TIP Rotational velocity is the same for all points of a rotating rigid body. It is independent of the radius—the distance of a chosen point on the rigid body from the axis of rotation.

To distinguish the rotational velocity from the familiar velocity that characterizes the linear motion of an object, the latter is called linear velocity. When an object rotates, each point of the object has *linear* velocity. If you examine Figure 9.1a you see that the linear velocity vectors are tangent to the circle. Thus the linear velocity of a point on a rotating object is sometimes called **tangential velocity**.

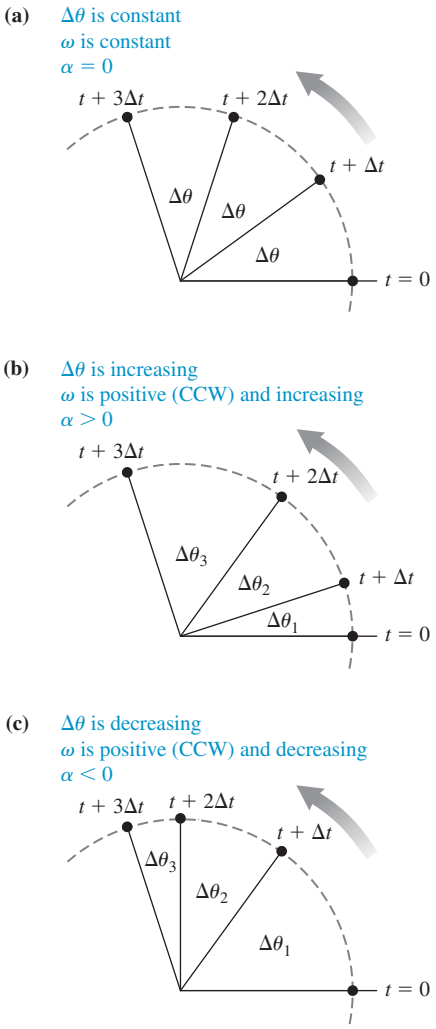
The **revolution** is a familiar unit from everyday life. One revolution (rev) corresponds to a complete rotation about a circle and equals 360°. The revolution is not a unit of rotational position. It is a unit of *change* in rotational position $\Delta\theta$. Revolutions are usually used to indicate change in rotational position per unit time. For example, a motor that makes 120 complete turns in 1 min is said to have a rotational speed of 120 revolutions per minute (120 rpm). Automobile engines rotate at about 2400 rpm.

TIP The definition of average rotational velocity or rotational speed becomes the instantaneous values of these quantities if you consider a small time interval in Eq. (9.2) and the corresponding small change in the rotational position. See our earlier discussion of instantaneous velocity in Section 2.7.

Rotational (angular) acceleration α

When we investigated the linear motion of a point-like object along a single axis, we developed the physical quantity acceleration to describe the object's change in velocity. This was translational acceleration, as it described the changing velocity of the object while moving from one position to another. We could apply the same translational acceleration idea to the center of mass of a rigid body that is moving as a whole from one position to another. But usually we are interested in the rate of change of the rigid body's rotational velocity, that is, its **rotational acceleration**. In other words, when the rotation rate of a rigid body increases or decreases, it has a nonzero rotational acceleration.

Rotational acceleration α The average rotational acceleration α (alpha) of a rotating rigid body (sometimes called angular acceleration) is its change in rotational velocity $\Delta\omega$ during a time interval Δt divided by that time interval:



$$\alpha = \frac{\Delta\omega}{\Delta t} \tag{9.3}$$

The unit of rotational acceleration is $(\text{rad/s})/\text{s} = \text{rad/s}^2$.

Figure 9.6 shows motion diagrams for three different types of rotational motion. Let's consider these rotational motion diagrams and try to develop a rule for how the sign of the rotational acceleration relates to the rotational velocity for a CCW-turning disk. Note that when the disk's rotational velocity is constant (the lengths of arcs between the dots are the same), its rotational acceleration is zero (Figure 9.6a). When its CCW rotational velocity (positive) is increasing (note that in Figure 9.6b the arcs between the dots increase in length), its rotational acceleration has the same sign (positive) as the rotational velocity. If the disk's CCW rotational velocity (positive) is decreasing (note that in Figure 9.6c the arcs between the dots are shrinking), its rotational acceleration has the opposite sign (negative). Similarly, when a disk is rotating CW (negative rotational velocity) faster and faster, its rotational acceleration has the same sign (negative). If the disk's clockwise rotational velocity (negative) is decreasing, its rotational acceleration has the opposite sign (positive).

What could we conclude about the signs of Earth's rotational velocity and acceleration if we were looking down on Earth from above the North Pole? The rotational velocity would have a positive sign (turning counterclockwise), and because the rotational velocity is constant, the rotational acceleration would be zero. (We will learn later that Earth's rotational velocity is not exactly constant.)

FIGURE 9.6 Three rotational motion diagrams and the corresponding signs of the rotational accelerations.

Relating translational and rotational quantities

Are there mathematical connections between physical quantities describing the rotational motion of a rigid body and the translational motion of different points on the body? Recall that the rotational position θ of a point on a turning object depends on the radial distance r of that point from the axis of rotation and the path length s measured along the arc connecting that point to the reference axis (see Figure 9.3):

$$s = r\theta \tag{9.1}$$

If the angle changes by $\Delta\theta$, the distance of the point of the object along the arc changes by Δs, so that

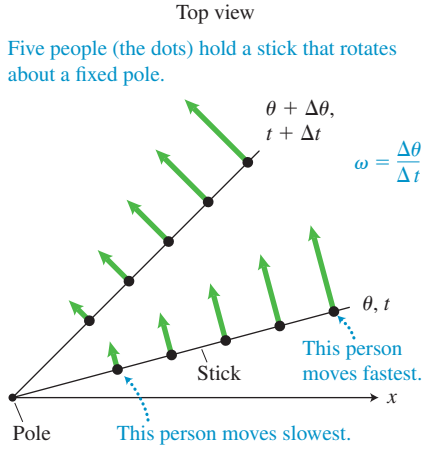
$$\Delta s = r\,\Delta\theta$$

Do similar relations exist for other quantities? Suppose, for example, that a point on the object changes rotational position by $\Delta\theta$ in a time interval Δt. Its rotational velocity is $\omega = \Delta\theta/\Delta t$. The change in arc length is Δs along its circular path, and its tangential speed (the speed of the object tangent to the circle, sometimes called linear speed) is $v_t = \Delta s/\Delta t$. Substituting for Δs, we get

$$v_t = \frac{\Delta s}{\Delta t} = \frac{r\,\Delta\theta}{\Delta t} = r\left(\frac{\Delta\theta}{\Delta t}\right) = r\omega \tag{9.4}$$

Notice that while the rotational speed of all points of the same rigid body is the same, the tangential (linear) speed of different points increases as their distance from the axis of rotation increases. A similar relationship can be derived that relates that point's acceleration a_t tangent to the circle and its rotational acceleration α:

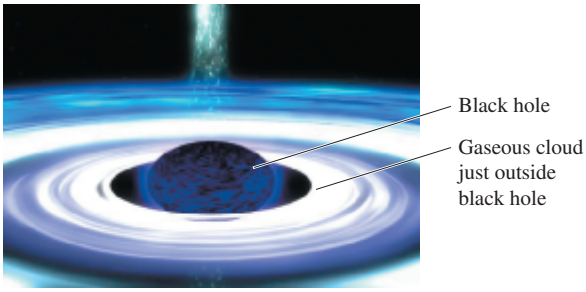
$$a_t = \frac{\Delta v_t}{\Delta t} = \frac{r\,\Delta\omega}{\Delta t} = r\left(\frac{\Delta\omega}{\Delta t}\right) = r\alpha \tag{9.5}$$



The signs of the rotational position and velocity are positive for counterclockwise turning, and the signs of the translational position and velocity are also positive for counterclockwise motion.

To visualize this relationship, imagine five people (the point objects in **Figure 9.7**) holding on to a long stick that can rotate horizontally about a vertical pole to which it is attached on one end. These people hold on to the stick as it completes a full circle. The person closest to the pole moves the slowest, the next person moves a little faster, and the one at the free end has to almost run to keep the stick in his hands. At a particular time, all of them have the same rotational position θ and the same rotational velocity ω. However, the linear distances and speeds are larger for the people farther from the axis of rotation (larger values of r).

Black holes are an extreme case of rotational motion. Black holes form when some stars at the end of their lives collapse, forming small, very dense objects. If the star was spinning when it was young, it continues to spin when it becomes a black hole, only much faster. The matter near the outer edge of the black hole is usually extremely hot gas that orbits the black hole with a tangential speed near the speed of light. The figure below is an artist's rendition of what such a black hole might look like, if we could see it.



TIP You get the familiar translational quantities for motion along the circular path by multiplying the corresponding angular rotational quantities by the radius r of the circle.

FIGURE 9.7 A top-view diagram of five people (represented by dots) holding on to a stick that rotates about a fixed pole.

QUANTITATIVE EXERCISE 9.1 **Orbiting a black hole**

Black hole GRS 1915+105 in the constellation Aquila (the Eagle) is about 35,000 light-years from Earth. It was formed when the core of a star with about 14 solar masses (mass of 14 times the mass of our Sun) collapsed. The boundary of the black hole, called the event horizon, is a sphere with radius about 25 km. Surrounding the black hole is a stable gaseous cloud with an innermost 30-km-radius stable circular orbit. This cloud moves in a circle about the black hole about 970 times per second. Determine the tangential speed of matter in this innermost stable orbit.

(CONTINUED)

Represent mathematically We model the cloud as a rotating disk with radius $r = 30{,}000$ m; to find the rotational speed we convert the rotations in revolutions per second into radians per second: $\omega = (970 \text{ rev/s})(2\pi \text{ rad/rev}) = 6100 \text{ rad/s}$. We need to find the tangential speed v_t of the particles of gas in orbit around the black hole, which is related to the radius r of the circular orbit and the rotational speed ω of the matter:

$$v_t = r\omega$$

Solve and evaluate The speed of the matter in the innermost stable orbit is

$$v_t = r\omega = (30{,}000 \text{ m})(6100 \text{ rad/s}) = 1.8 \times 10^8 \text{ m/s}$$

This is slightly more than half the speed of light! Actually, the physics we have developed is only moderately applicable in this environment of extreme gravitational forces and high speeds. Our answer is about 20% high compared to a more sophisticated analysis done using Einstein's theory of general relativity. Nevertheless, using ideas from uniform circular motion, we estimate that the radial acceleration of matter moving in that circular orbit is about $v^2/r \approx 10^{11}g$. It's not a good place to visit.

Try it yourself You ride a carnival merry-go-round and are 4.0 m from its center. A motion detector held by your friend next to the merry-go-round indicates that you are traveling at a tangential speed of 5.0 m/s. What are the rotational speed and time interval needed to complete one revolution on the merry-go-round?

Answer $\omega = 1.3 \text{ rad/s}; T = 5.0 \text{ s}.$

Rotational motion at constant acceleration

Earlier, we developed equations that related the physical quantities *t, x, v,* and *a,* which we used to describe the translational motion of a point-like object along a single axis with constant acceleration. Similar equations relate the rotational kinematics quantities t, θ, ω, and α, assuming the rotational acceleration is constant. We're not going to develop them based on observations in the way we did for the equations of translational motion, since the process will be nearly the same. Instead, we will rely on the connections we have seen between the translational and rotational quantities. The analogous rotational motion equations are provided in **Table 9.1** along with the corresponding translational motion equations. Because the quantities that describe motion depend on the choice of the reference frame, always note the location of the observer in a particular situation.

TABLE 9.1 Equations of kinematics for translational motion with constant acceleration and the analogous equations for rotational motion with constant rotational acceleration

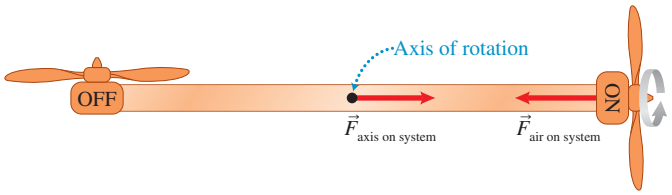
Translational motion	Rotational motion	
$v_x = v_{0x} + a_x t$	$\omega = \omega_0 + \alpha t$	(9.3)
$x = x_0 + v_{0x}t + \frac{1}{2}a_x t^2$	$\theta = \theta_0 + \omega_0 t + \frac{1}{2}\alpha t^2$	(9.6)
$2a_x(x - x_0) = v_x^2 - v_{0x}^2$	$2\alpha(\theta - \theta_0) = \omega^2 - \omega_0^2$	(9.7)

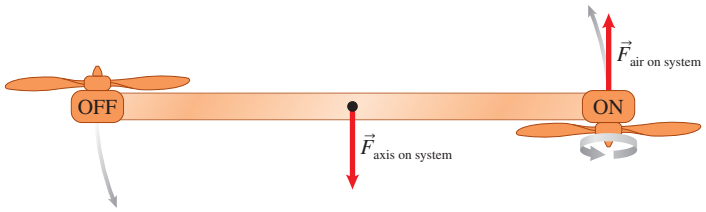
For rotational motion, θ_0 is an object's rotational position at time $t_0 = 0$; ω_0 is the object's rotational velocity at time $t_0 = 0$; θ and ω are the rotational position and rotational velocity at some later time t; and α is the object's constant rotational acceleration during the time interval from time zero to time t.

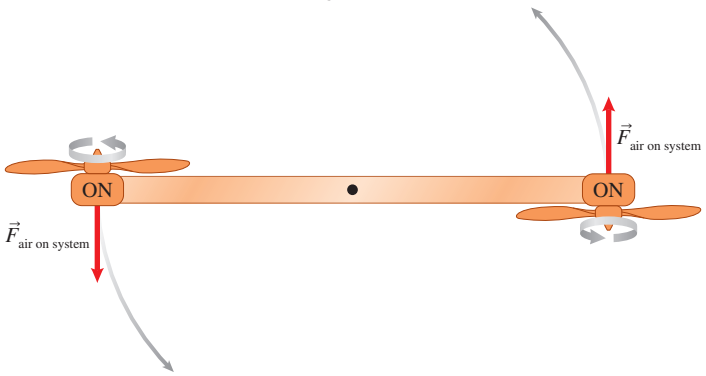
- The sign of the rotational position is positive for counterclockwise θ and negative for clockwise θ from the reference axis.
- The sign of the rotational velocity ω depends on whether the object is rotating counterclockwise $(+)$ or clockwise $(-)$.
- The sign of the rotational acceleration α depends on how the rotational velocity is changing; α has the same sign as ω if the magnitude of ω is increasing and the opposite sign of ω if ω's magnitude is decreasing.

REVIEW QUESTION 9.1 Visualize an ice skater rotating faster and faster in a clockwise direction. What are the signs of rotational velocity and rotational acceleration? As the skater starts slowing down, what are the signs of rotational velocity and acceleration?

9.2 Physical quantities affecting rotational acceleration

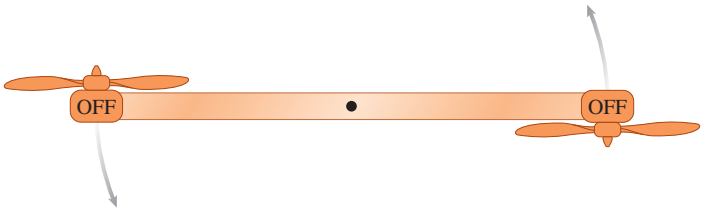






What causes a rigid body to have a particular rotational acceleration? When we investigated translational motion we learned that the acceleration of a point-like object was determined by its interactions with other objects, that is, forces that objects in the environment exerted on it. Perhaps there is an analogous way to think about what causes rotational acceleration. In the last chapter, we learned that the net torque produced by forces exerted on a system had to equal zero for the object to remain in static equilibrium, to not start rotating. What happens when the net torque isn't zero? Let's investigate this. In Observational Experiment **Table 9.2**, we perform experiments with a metal arm that can rotate freely around a vertical axis. We attach to the arm two fans that we can turn on and off and move along the arm (**Figure 9.8**).

FIGURE 9.8 The equipment for the experiments in Table 9.2.



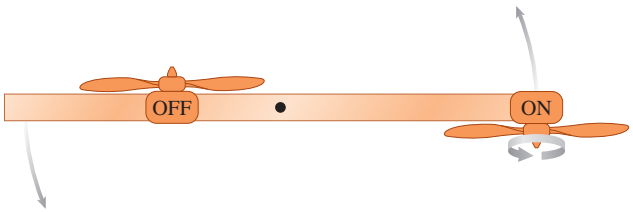
OBSERVATIONAL EXPERIMENT TABLE 9.2 Turning effects of forces exerted on a rotating arm

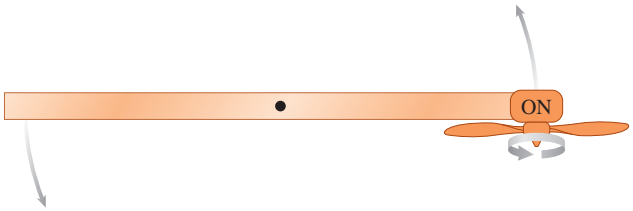
VIDEO OET 9.2

Observational experiment	Analysis
Experiment 1. Two fans are fixed on the arm. One fan is switched on, and it pushes air along the arm. The arm does not rotate. (Note that all figures show the top view of the experimental setup.) 	The arm with the fans is the system. The horizontal forces are shown in the figure at left. Because the arm does not accelerate translationally, $\vec{a}_1 = 0$. This is only possible when $\Sigma\vec{F} = 0$. The force exerted by the air on the system and the force exerted by the axis on the system therefore add to zero. The arm does not rotate ($\omega_1 = 0$) or accelerate rotationally ($\alpha_1 = 0$). This is only possible when $\Sigma\tau = 0$; in this case, the torques produced by both forces are equal to zero.
Experiment 2. The turned-on fan rotates so that it pushes air perpendicular to the arm. When the fan is on, the arm rotates faster and faster. We determine its rotational acceleration by measuring the change in rotational velocity and the time interval. 	The air exerts a force on the fan and the arm and causes a positive torque, $\tau_2 > 0$. The arm has increasing positive rotational velocity and a positive rotational acceleration, $\alpha_2 > 0$. The arm does not accelerate translationally, $\vec{a}_2 = 0$; this is only possible when the sum of the forces exerted on it is zero, $\Sigma\vec{F} = 0$.
Experiment 3. Both fans are turned on so that air pushes on the fans and the arm in opposite directions. The arm rotates faster and faster, with the rotational acceleration twice as large as before. 	The air pushing on the fans and the arm creates two torques of the same magnitude that are both positive: $\Sigma\vec{F} = 0$ $\vec{a}_3 = 0$ $\tau_2 + \tau_3 = 2\tau_2$ $\alpha_3 = 2\alpha_2$

(CONTINUED)

Observational experiment	Analysis
Experiment 4. While the arm is rotating, you simultaneously turn off the fans. The arm continues to rotate at a constant rotational velocity. 	$\Sigma\vec{F} = 0$ $\vec{a}_4 = 0$ $\Sigma\tau = 0$ $\alpha_4 = 0$ $\omega \neq 0$





Patterns

- An external force that produces a zero torque on the arm does not change the arm's rotational velocity. If the arm is at rest, it remains at rest.
- When there are no external forces exerting torques on a rotating arm, its rotational velocity remains constant.
- External forces that produce a nonzero net torque on the arm cause rotational acceleration. Doubling the net torque doubles the rotational acceleration of the arm.

Using these patterns, we can hypothesize that the rotational acceleration of an object with fixed axis of rotation depends on the external net torque exerted on the object. But is it just the torque that determines the acceleration? In translational motion, the other quantity affecting translational acceleration was the mass of the object. What is the analogous quantity in rotational motion? Could it be the mass, too? Let's test the hypothesis that the rotational acceleration depends on the sum of the external torques and the mass of the object in Testing Experiment **Table 9.3**.

TESTING EXPERIMENT TABLE 9.3  **Testing the hypothesis that mass affects rotational acceleration**

VIDEO TET 9.3

Testing experiment	Prediction	Outcome
Experiment 1. Repeat Experiment 2 from Table 9.2, but this time move the turned-off fan closer to the axis of rotation. 	If the rotational acceleration depends on the external torques and the mass of the system and we have the same fans as in Experiment 2 from Table 9.2, then changing the location of the turned-off fan should not change the rotational acceleration of the system.	The rotational acceleration of the arm is greater than in Experiment 2 from Table 9.2.
Experiment 2. Remove the turned-off fan from the arm and repeat Experiment 2 from Table 9.2. 	Because the mass of the system decreases, the rotational acceleration should increase.	The rotational acceleration of the arm is greater than in Experiment 2 from Table 9.2 and greater than in Experiment 1 above.

Conclusion

Although we found that the mass of the system affects its rotational acceleration, we rejected the hypothesis that the rotational acceleration depends *only* on the net exerted torque and the mass of the object. We found that the distribution of mass with respect to the axis of rotation is important, too.

We found that the distribution of mass with respect to the axis of rotation affects an object's rotational acceleration. A simple experiment that you can perform in your kitchen helps you "feel" the effect of mass distribution with respect to the axis of rotation. Lay a broom on a hard, smooth floor. First, try to increase the broom's rotational speed about a vertical axis by spinning it with one hand holding the broomstick near the end opposite the broom head. Then do it again while holding the broom in the middle, nearer the broom head. It is much easier to increase the rotational speed while holding it in the middle. You are turning the same mass, but the location of that mass with respect to the axis of rotation makes a difference—just as we found in Table 9.3.

We can now summarize two patterns that we have discovered so far:

Changes in rotational velocity Rotational acceleration depends on net torque. The greater the net torque, the greater the rotational acceleration. Rotational acceleration also depends on the total mass of the object and the mass distribution with respect to the axis of rotation.

Let us focus on the *distribution* of mass of the rotating object. The closer the mass of the object to the axis of rotation, the easier it is to change its rotational motion. We call the physical quantity characterizing the location of the mass relative to the axis of rotation the **rotational inertia** (also known as the **moment of inertia**) of the object. Rotational inertia I depends on both the total mass of the object and the distribution of that mass about its axis of rotation. For objects of the same mass, the more mass that is located near the axis of rotation, the smaller the object's rotational inertia will be. Likewise, the more mass that is located farther away from the axis of rotation, the greater the object's rotational inertia will be. For objects of different mass but the same mass distribution, the more massive object has more rotational inertia. The higher the rotational inertia of an object, the harder it is to change its rotational motion. In summary, this quantity is the rotational equivalent of mass.

We have now found two factors that affect the rotational acceleration of an object:

- The rotational inertia of the object
- The net torque produced by forces exerted on the object

Notice how this is similar to what we learned when studying translational motion. A nonzero net force (sum of the forces) needs to be exerted on an object to cause its velocity to change. The greater the net force, the greater the translational acceleration of the object. The mass of the object affects its acceleration, too—the greater the mass, the smaller the acceleration for the same net force.

Remember that in all of the experiments we have performed so far in this chapter, rotational motion was all that was possible. Each rigid body was rotating about a fixed axis through its center of mass. If the rigid body were not held fixed, then a change in both translational and rotational motion could occur. The translational acceleration of the center of mass of such an object is determined by Newton's second law $\vec{a} = \Sigma\vec{F}/m$. The rotational acceleration around its center of mass will be determined by the ideas we will investigate over the next several sections.

REVIEW QUESTION 9.2 A solid wooden ball and a smaller solid metal ball have equal mass (the metal ball is smaller because it is much denser than wood). Both can rotate on an axis going through their centers. You exert a force on each that produces the same torque about the axis of rotation. Which sphere's rotational motion will change the least? Explain.

9.3 Newton's second law for rotational motion

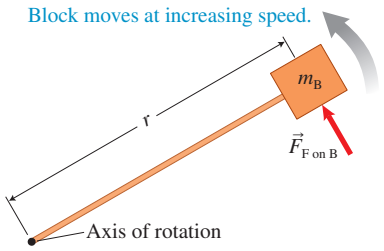


FIGURE 9.9 A top view of an experiment to relate torque and rotational acceleration.

To construct a quantitative relation between rotational acceleration, net torque, and rotational inertia we start with a simple example of rotational motion: a small block attached to a light stick that can move on a smooth surface in a circular path (**Figure 9.9**). The axis of rotation passes through a pin at the other end of the stick. After we analyze this case, we will generalize the result to the rotation of an extended rigid body. You push the block with your finger, exerting a small force $\vec{F}_{\text{F on B}}$ on the block tangent to the circular path. This push causes a torque, which in turn causes the block and stick's rotational velocity about the pin to increase.

The torque produced by the force $\vec{F}_{\text{F on B}}$ is

$$\tau = rF_{\text{F on B}} \sin\theta = rF_{\text{F on B}} \sin 90^\circ = rF_{\text{F on B}}$$

Since the block is small, we can reasonably model it as a point-like object. This allows us to apply Newton's second law. Since the mass of the block is much larger than the mass of the stick, we assume that the stick has no mass. The finger exerts a force of constant magnitude pushing lightly in a direction tangent to the block's circular path. Thus, the tangential component of Newton's second law for the block is

$$a_t = \frac{F_{\text{F on B}}}{m_B}$$

There is a mathematical way to get the torque produced by the pushing force. Rearrange the above equation to get

$$m_B a_t = F_{\text{F on B}}$$

Then multiply both sides of the equation by r, the radius of the circular path:

$$m_B\, r\, a_t = rF_{\text{F on B}}$$

Recall from Eq. (9.5) that $a_t = r\alpha$. Thus,

$$m_B\, r\, (r\alpha) = rF_{\text{F on B}}$$

The right side of this equation equals the torque τ caused by $\vec{F}_{\text{F on B}}$:

$$(m_B r^2)\, \alpha = \tau$$

$$\Rightarrow \alpha = \frac{\tau}{m_B r^2}$$

Examine the above equation and compare it to Newton's second law for the same object—the block not only acquires translational acceleration a_t due to the force exerted on it by the finger, but also acquires rotational acceleration around the axis caused by the torque produced by that same force. This rotational acceleration is directly proportional to the torque produced by the force and inversely proportional to the mass of the block times the square of the distance between the block and the axis of rotation. The latter makes sense—we found experimentally that the farther the mass of the object is from the axis of rotation, the harder it is to change its rotational velocity. Thus the denominator in the equation above is an excellent candidate for the rotational inertia of the block about the pin (the axis of rotation in this situation).

In the above thought experiment, there was just a single force exerted on the object producing a torque about the axis of rotation. More generally, there could be several forces producing torques. It's reasonable that we should add the torques produced by all forces exerted on the object to determine its rotational acceleration:

$$\alpha = \frac{1}{m_B r^2} \Sigma\tau = \frac{1}{m_B r^2} (\tau_1 + \tau_2 + \dots) \tag{9.8}$$

where $\tau_1, \tau_2, \dots$ are the torques produced by forces $\vec{F}_{1\text{ on O}}, \vec{F}_{2\text{ on O}}, \dots$ exerted on the object.

Analogy between translational motion and rotational motion

Notice how similar Eq. (9.8)

$$\alpha = \frac{1}{m_B r^2}\Sigma\tau$$

is to Newton's second law for translational motion

$$\vec{a} = \frac{1}{m}\Sigma\vec{F}$$

When forces are exerted on a point-like object, we can describe its motion using two acceleration-type quantities—translational and rotational acceleration when the axis around which the object rotates is located outside the object. The translational acceleration is determined by Newton's second law, and the rotational acceleration is determined by Eq. (9.8), called **Newton's second law for rotational motion**. There is a strong analogy between each of the three quantities in the two equations (see **Table 9.4**).

For translational motion, mass is a measure of an object's resistance to the changes in its translational motion. For the rotational motion of a point-like object, the object's mass times the square of its distance r from the axis of rotation (mr^2) is a measure of the object's resistance to the changes in its rotational motion. In summary, the quantity mr^2 is the rotational inertia I of a point-like object of mass m around the axis that is the distance r from the location of the object.

For translational motion, the net force $\Sigma\vec{F}$ exerted on an object of interest by other objects causes that object's velocity to change—it has a translational acceleration $(\vec{a} = \Delta\vec{v}/\Delta t)$. For rotational motion, the net torque $\Sigma\tau$ produced by forces exerted on the object causes its rotational velocity to change—it has a rotational acceleration $(\alpha = \Delta\omega/\Delta t)$.

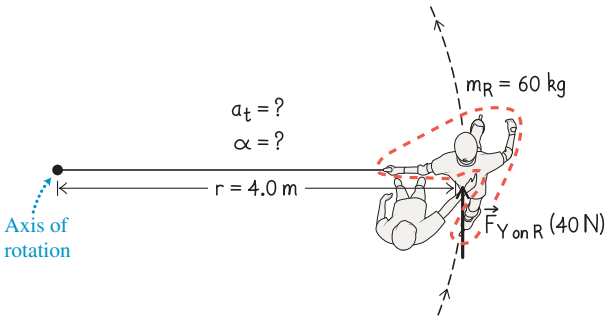

TABLE 9.4 Analogy between translational and rotational quantities in Newton's second law

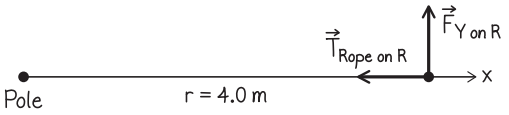
	Translational motion	Rotational motion
Inertia of a point-like object	m	mr^2
Cause of acceleration	$\Sigma\vec{F}$	$\Sigma\tau$
Acceleration	$\vec{a}$	α



EXAMPLE 9.2 Pushing a Rollerblader

A 60-kg Rollerblader holds a 4.0-m-long rope that is loosely tied around a metal pole. You push the Rollerblader, exerting a 40-N force on her, which causes her to move increasingly fast in a counterclockwise circle around the pole. The surface she skates on is smooth, and the wheels of her Rollerblades are well oiled. Determine the tangential and rotational acceleration of the Rollerblader.

Sketch and translate We sketch the situation as shown below. We choose the Rollerblader as the object of interest.

Simplify and diagram Since the size of the Rollerblader is small compared to the length of the rope, we can model her as a point-like object. The following figure shows a force diagram for the Rollerblader (viewed from above). Her tangential acceleration has no vertical component along a vertical axis (which would extend up and out of the page in the figure). The upward normal force $\vec{N}_{F\text{ on }R}$ that the floor exerts on her balances the downward gravitational force $\vec{F}_{E\text{ on }R}$ exerted by Earth on her (these forces are not shown in the figure). The tension force exerted by the rope on the Rollerblader $\vec{T}_{\text{Rope on R}}$ points directly toward the axis of rotation, so that force produces no torque.

Represent mathematically From the force diagram we conclude that your push $\vec{F}_{Y\text{ on R}}$ on the Rollerblader is the only force that produces a nonzero torque $\tau = rF_{Y\text{ on R}}\sin 90° = rF_{Y\text{ on R}}$, where r is the radius of the Rollerblader's circular path.

Use Newton's second law in the tangential direction to determine the Rollerblader's tangential acceleration:

$$a_t = \frac{1}{m_R}\Sigma F_t = \frac{F_{Y\text{ on R}}}{m_R}$$

Use Newton's second law for rotational motion [Eq. (9.8)] to determine the Rollerblader's rotational acceleration:

$$\alpha = \frac{1}{m_R r^2}\Sigma\tau = \frac{1}{m_R r^2}\tau_{Y\text{ on R}} = \frac{1}{m_R r^2}(rF_{Y\text{ on R}}) = \frac{F_{Y\text{ on R}}}{m_R r}$$

Solve and evaluate For the tangential acceleration:

$$a_t = \frac{F_{Y\text{ on R}}}{m_R} = \frac{40\text{ N}}{60\text{ kg}} = 0.67\text{ m/s}^2$$

(CONTINUED)

For the rotational acceleration:

$$\alpha = \frac{F_{\text{Y on R}}}{m_R r} = \frac{40\text{ N}}{(60\text{ kg})(4.0\text{ m})} = 0.17\text{ rad/s}^2$$

Let's check the units; note that $\frac{\text{N}}{\text{kg m}} = \frac{\text{kg}\cdot\text{m}}{\text{s}^2\cdot\text{kg m}} = \frac{1}{\text{s}^2}$. Remember that the radian is not an actual unit. It is dimensionless. It is just a reminder that this is the angle unit appropriate for these calculations. So the units are correct, and the magnitudes for both results are reasonable. The Rollerblader would have a rotational velocity of 0.17 rad/s after 1 s, 0.34 rad/s after 2 s, and so forth—the rotational velocity increases 0.17 rad/s each second.

Try it yourself Suppose you exerted the same force on your friend, but the friend is holding an 8.0-m-long rope instead of a 4.0-m-long rope. How will this affect the rotational acceleration?

Answer The tangential acceleration will not change, but the rotational acceleration will be half as large. The torque will be doubled because the distance from the axis of rotation to the point where the force is applied will be doubled. But the rotational inertia (mr^2) in the denominator will be quadrupled because of the r^2. The combination will be a reduction of the rotational acceleration by half—0.08 rad/s^2.

Newton's second law for rotational motion applied to rigid bodies

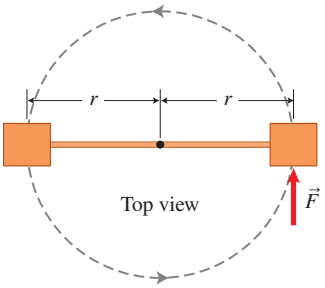
We know that the mass of an object composed of many small objects with masses m_1, m_2, m_3, etc. is the sum of the masses of its parts: $m = m_1 + m_2 + m_3 + \ldots$. Mass is a scalar quantity and therefore is always positive. The rotational inertia of a point-like object with respect to some axis of rotation is a scalar quantity. Thus, it is reasonable to think that the same rule applies to rigid bodies: the rotational inertia of a rigid body about some axis of rotation is the sum of the rotational inertias of the individual point-like objects that make up the rigid body.

To test this idea, we can use it to calculate the rotational inertia of a lightweight stick with a block attached to each end, as shown in **Figure 9.10a**. The axis of rotation is at the middle of the stick. If our reasoning is correct, the rotational inertia of this two-block rigid body should be twice the rotational inertia of a single block at the end of a stick that is half the length (Figure 9.10b): $I_{\text{Two block}} = 2I_{\text{One block}}$.

If this is correct, and we exert the same torque ($\tau = rF\sin 90° = rF$) on the two-block–stick system, the rotational acceleration of this system should be half the rotational acceleration of the one-block–stick system:

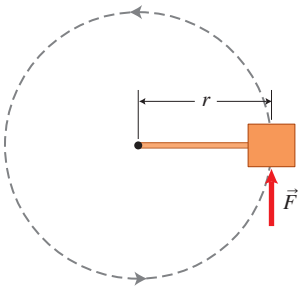
$$\alpha_{\text{Two block}} = \frac{\tau}{I_{\text{Two block}}} = \frac{\tau}{2I_{\text{One block}}} = \frac{1}{2}\left(\frac{\tau}{I_{\text{One block}}}\right) = \frac{1}{2}\alpha_{\text{One block}}$$

We check this prediction by performing a testing experiment. We exert the same force on the two-block system and the one-block system, thus producing the same torque, and measure the angular acceleration of each system. The outcome matches the above prediction. The rotational inertia of the two-block system is twice that of the one-block system.



It appears that the rotational inertia of a rigid body that consists of several point-like parts located at different distances from the axis of rotation is the sum of the mr^2 terms for each part:

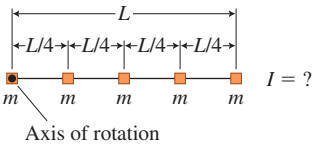
$$I = m_1 r_1^2 + m_2 r_2^2 + \ldots$$



Let's apply this idea.

FIGURE 9.10 Comparing the effect of rotational inertia on rotational acceleration.

(a) The rotational inertia I of the two-block system should be twice that of the one-block system.



(b)

Thus, we predict that with equal torque and using $\alpha = \tau/I$, $\alpha_{\text{One block}} = 2\alpha_{\text{Two block}}$.

QUANTITATIVE EXERCISE 9.3 **Rotational inertia of a rigid body**

Use what you learned about rotational inertia to write an expression for the rotational inertia of the rigid body shown at right. Each of the five blocks has mass m. They are connected with lightweight sticks of equal length $L/4$.

Represent mathematically Each block of mass m contributes differently to the rotational inertia of the system. The farther the block from the axis of rotation, the greater its contribution to the rotational inertia of the system of blocks. We can add the rotational inertia of each block of mass m about the axis of rotation:

$$I = m(0)^2 + m(L/4)^2 + m(2L/4)^2 + m(3L/4)^2 + m(4L/4)^2$$

Solve and evaluate When added together, the rotational inertia of the five-block system is $I = 1.88mL^2$. Each block (except the one located at the axis of rotation) contributes to the system's rotational inertia. However, blocks farther from the axis of rotation contribute much more than those near the axis. In fact, the block at the right side of the rod contributes more to the rod's rotational inertia (mL^2) than the other four blocks combined ($0.88mL^2$).

Try it yourself Calculate the rotational inertia of the same system altered so that the axis of rotation passes perpendicular through the central block.

Answer $0.625mL^2$.

Calculating rotational inertia

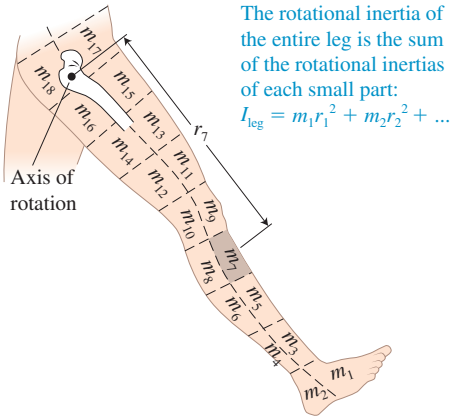
We can calculate the rotational inertia of a rigid body about a specific axis of rotation in about the same way we determined the rotational inertia of the five-block system in Quantitative Exercise 9.3, by adding the rotational inertias of each part of the entire system. However, for most rigid bodies, the parts are not separate objects but are instead parts in a continuous distribution of mass—like in a door or baseball bat. In such a case, we break the continuous distribution of mass into very small pieces and add the rotational inertias for all of the pieces. Consider the person's leg shown in **Figure 9.11**, which we model as a rigid body if none of the joints bend. For example, mass element 7 contributes an amount $m_7r_7^2$ to the rotational inertia of the leg. The rotational inertia of the whole leg is then

$$I = m_1r_1^2 + m_2r_2^2 + \ldots + m_7r_7^2 + \ldots + m_{18}r_{18}^2 \qquad (9.9)$$

All r's in the above are from the same axis of rotation. The rotational inertia would be different if we chose a different axis of rotation. There are other ways to do the summation process in Eq. (9.9); often it is done using integral calculus, and sometimes I is determined experimentally.

Table 9.5 gives the rotational inertias of some common *uniform* objects (a uniform object is made of the same material throughout) for specific axes of rotation. Notice the coefficients in front of the mR^2 and mL^2 expressions for the objects of different shapes. The value of the coefficient is determined by the mass distribution inside the object and the location of the axis of rotation.

FIGURE 9.11 Add the mr^2 of all the small parts to find the rotational inertia I of the leg.



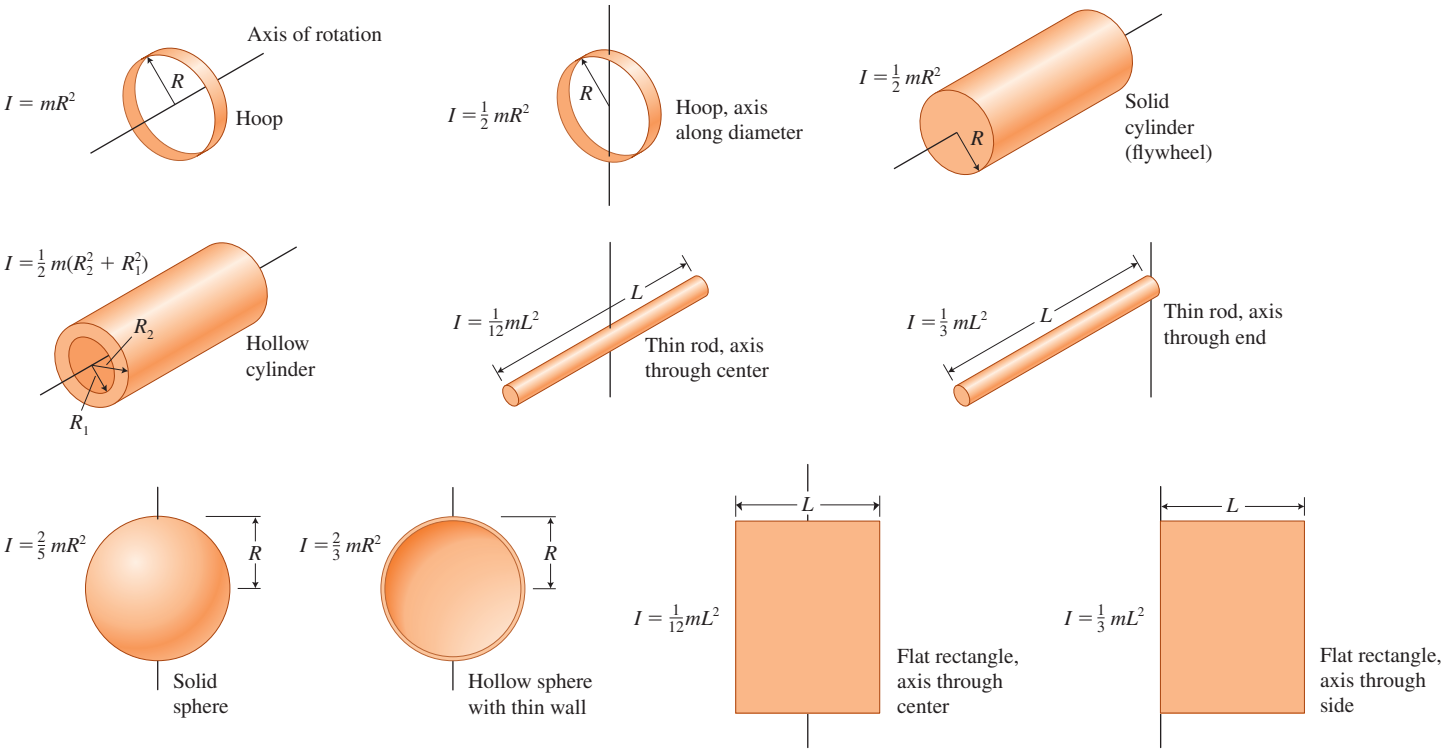


TABLE 9.5 Expressions for the rotational inertia of standard shape objects

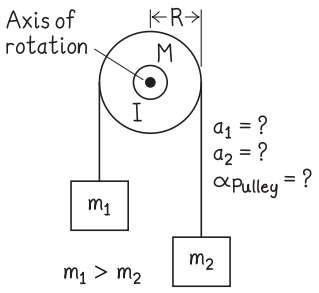
We can now rewrite the rotational form of Newton's second law in terms of the rotational inertia of the rigid body.

Rotational form of Newton's second law One or more objects exert forces on a rigid body with rotational inertia I that can rotate about some axis. The sum of the torques $\Sigma\tau$ due to these forces about that axis causes the object to have a rotational acceleration α:

$$\alpha = \frac{1}{I}\Sigma\tau \tag{9.10}$$

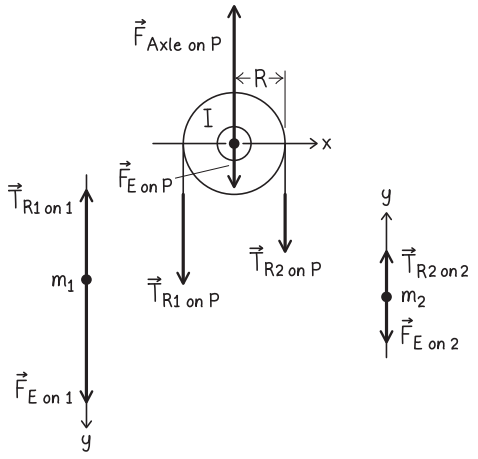
TIP By writing Newton's second law in the form

$$\vec{a}_S = \frac{1}{m_S}\Sigma\vec{F}_{\text{on S}} = \frac{\vec{F}_{O_1\text{ on S}} + \vec{F}_{O_2\text{ on S}} + \ldots + \vec{F}_{O_n\text{ on S}}}{m_S}$$



we see the cause-effect relationship between the net force $\Sigma\vec{F}_{\text{on S}}$ exerted on the system and the system's resulting translational acceleration $\vec{a}_S$. The same idea is seen in Eq. (9.10), only applied to the rotational acceleration:

$$\alpha_S = \frac{1}{I_S}\Sigma\tau = \frac{\tau_1 + \tau_2 + \ldots + \tau_n}{I_S}$$



EXAMPLE 9.4 Atwood machine

In an Atwood machine, a block of mass m_1 and a less massive block of mass m_2 are connected by a string that passes over a pulley of mass M and radius R. What are the translational accelerations a_1 and a_2 of the two blocks and the rotational acceleration α of the pulley?

Sketch and translate A sketch of the situation is shown here. You might recall that we analyzed a similar situation previously (in Section 4.4). However, at that time we assumed that the pulley had negligible (zero) mass. We had no choice but to make that assumption because we had not yet developed the physics for rotating rigid bodies. Now that we have, we can analyze the situation in different ways depending on the choice of system. We analyze the situation using three separate systems: block 1, block 2, and the pulley, and then combine the analyses to answer the questions.

Simplify and diagram We model the blocks as point-like objects and the pulley as a rigid body. Force diagrams for all three objects are shown at top right. A string wrapped around the rim of a pulley (or any disk/cylinder) pulls purely tangentially, so the torque it produces is simply the product of the magnitude of the force and the radius of the pulley. Previously, we assumed that the force exerted by the string pulling down on each side of the massless and frictionless pulley was the same—the pulley just changed the direction of the string but not the tension it exerted on the blocks below. Now, with a pulley with nonzero mass, the forces that the string exerts on two sides are different. If they were not, the pulley would not have a rotational acceleration. We assume that the string does not stretch (the translational acceleration of the blocks will have the same magnitude $a_1 = a_2 = a$) and that the string does not slip on the pulley (a point on the edge of the pulley has the same translational acceleration as the blocks). We also assume that the pulley's axle is oiled enough that the frictional torque can be ignored.

The translational acceleration of the hanging objects is due to the difference between the gravitational force that Earth exerts on them and the tension force that the string exerts on them. The rotational acceleration of the pulley is due to a nonzero net torque produced by the two tension forces exerted on the pulley.

We consider the pulley to be similar to a solid cylinder. Then according to Table 9.5, its rotational inertia around the axis that passes through its center is $I = \frac{1}{2}MR^2$, where R is the radius of the pulley and M is its mass.

Represent mathematically The force diagrams help us apply Newton's second law in component form for the two blocks and the rotational form for the pulley. The coordinate systems used in each case are shown. We choose the coordinate systems so the translational accelerations of both blocks are positive.

Block on the left: $m_1 a = +m_1 g + (-T_{\text{R1 on 1}})$

Block on the right: $m_2 a = -m_2 g + T_{\text{R2 on 2}}$

The pulley: $T_{\text{R1 on P}} R + (-T_{\text{R2 on P}} R) = I\alpha = \left(\frac{MR^2}{2}\right)\left(\frac{a}{R}\right)$

$$\Rightarrow (T_{\text{R1 on 1}})R - (T_{\text{R2 on 2}})R = \frac{MRa}{2}$$

$$\Rightarrow T_{\text{R1 on 1}} - T_{\text{R2 on 2}} = \frac{Ma}{2}$$

We now have three equations with three unknowns—the two tension forces exerted by the rope on the pulley and the magnitude of the acceleration a of the blocks. We can write expressions for $T_{\text{R1 on 1}}$ and $T_{\text{R2 on 2}}$ using the first two equations. We then have

$$T_{\text{R1 on 1}} = m_1 g - m_1 a$$

$$T_{\text{R2 on 2}} = m_2 g + m_2 a$$

After substituting these expressions for the rope forces into the pulley equation, we get

$$(m_1 g - m_1 a) - (m_2 g + m_2 a) = Ma/2$$

Solve and evaluate This equation can be rearranged to get an expression for the translational acceleration of the blocks:

$$a = \frac{m_1 - m_2}{\frac{1}{2}M + m_1 + m_2} g$$

Notice that if we neglect the mass of the pulley, the acceleration becomes

$$a = \frac{m_1 - m_2}{m_1 + m_2} g$$

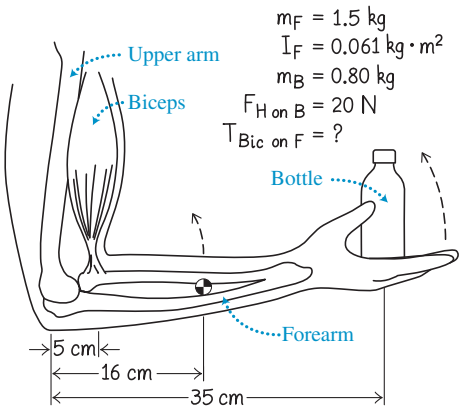
a larger acceleration than with the pulley (and consistent with the result we got in Chapter 4). Thus, the massive pulley decreases the acceleration of the blocks, which makes sense. If the pulley mass M is much heavier than the masses of the hanging objects m_1 and m_2, the acceleration becomes very small—it is almost like the blocks are hanging from a fixed massive object and not moving at all. We can find the rotational acceleration of the pulley by dividing the translational acceleration by the radius of the pulley because the string does not slip on the pulley.

$$\alpha = \frac{a}{R} = \left(\frac{m_1 - m_2}{\frac{1}{2}M + m_1 + m_2}\right)\frac{g}{R}$$

Try it yourself Determine the translational acceleration of the blocks and the rotational acceleration of the pulley for the following given information: $m_1 = 1.2$ kg, $m_2 = 0.8$ kg, $M = 1.0$ kg, and $R = 0.20$ m.

Answer $a = 1.6\ \text{m/s}^2$ and $\alpha = 7.8\ \text{rad/s}^2$.

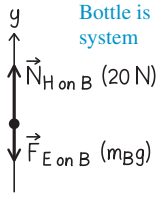
Notice the calculations of the translational acceleration of the blocks in Example 9.4. The acceleration is equal to the sum of the forces divided by an effective total mass of the system.



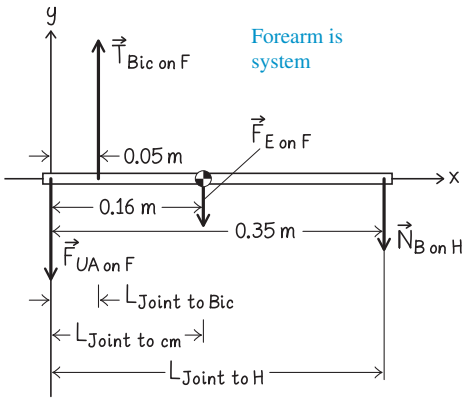
$$a = \frac{m_1 - m_2}{\frac{1}{2}M + m_1 + m_2} g$$

Here you see that the pulley only contributes half of its mass due to its mass distribution. We can say that the pulley's "effective mass" is $M/2$ because of how its mass is distributed.

EXAMPLE 9.5 Throwing a bottle



A woman tosses a 0.80-kg soft drink bottle vertically upward to a friend on a balcony above. At the beginning of the toss, her forearm rotates upward from the horizontal so that her hand exerts a 20-N upward force on the bottle. Determine the force that her biceps exerts on her forearm during this initial instant of the throw. The mass of her forearm is 1.5 kg, and its rotational inertia about the elbow joint is 0.061 kg · m^2. The attachment point of the biceps muscle is 5.0 cm from the elbow joint, the hand is 35 cm away from the elbow, and the center of mass of the forearm/hand is 16 cm from the elbow.



Sketch and translate A sketch of the situation is shown at right. There is no information given about the kinematics of the process (for example, no way to directly determine the rotational acceleration of her arm). How can we use the rotational form of Newton's second law to determine the unknown force that the biceps muscle exerts on the woman's forearm during the throw? We do know the force her hand exerts on the bottle and the bottle's mass. So, in the first part of the problem, we can first use the translational form of Newton's second law with the bottle as the system to find the bottle's vertical acceleration at the beginning of the throw. We can then use this acceleration to find the angular acceleration of the arm and then finally use the rotational form of Newton's second law to find the force that the biceps muscle exerts on her arm during the throw. For this second part of the problem, we choose the lower arm and hand as the system of interest. The axis of rotation is at the elbow joint between the upper arm and the forearm.

(CONTINUED)

Simplify and diagram The figure at right is a force diagram for the bottle as a system. Earth exerts a downward 7.8-N gravitational force $\vec{F}_{\text{E on B}}$ on the bottle and the woman's hand exerts an upward 20-N normal force $\vec{N}_{\text{H on B}}$ on the bottle. Since these forces do not cancel, the bottle has an initial upward acceleration. Next, consider the forearm and hand as the system. Assume that the forearm and hand form a rigid body. The bottle exerts a downward 20-N force on her hand $\vec{N}_{\text{B on H}}$. Earth exerts a downward gravitational force $\vec{F}_{\text{E on F}}$ on the forearm at its center of mass. Her biceps muscle exerts an upward tension force $\vec{T}_{\text{Bic on F}}$. The upper arm presses down on the forearm at the joint, exerting a force $\vec{F}_{\text{UA on F}}$. If the upper arm did not push down, the forearm at the joint would fly upward when the biceps muscle pulled up on it.

Represent mathematically We first analyze the bottle's motion to determine its translational acceleration; then determine the rotational acceleration of the forearm and hand system; and finally apply the rotational form of Newton's second law to find the force that the biceps needs to exert on the system to cause this rotational acceleration. Consider the initial instant of the bottle's upward trip. The *y*-component form of Newton's second law applied to the bottle can be used to determine the vertical acceleration $a_{\text{B}y}$ for the bottle:

$$a_{\text{B}y} = \frac{N_{\text{H on B}\,y} + F_{\text{E on B}\,y}}{m_{\text{B}}} = \frac{N_{\text{H on B}} + (-m_{\text{B}}g)}{m_{\text{B}}}$$

The rotational acceleration of the forearm/hand system at that instant is related to the vertical acceleration of the bottle:

$$\alpha_{\text{F}} = \frac{a_{\text{B}y}}{r}$$

where r is the distance from the axis of rotation to the hand. The magnitude of the force that the biceps muscle exerts on the forearm ($T_{\text{Bic on F}}$) can be determined using the rotational form of Newton's second law applied to the forearm/hand. Notice that here the system consists of different parts joined together.

$$T_{\text{Bic on F}}L_{\text{Joint to Bic}} + (-F_{\text{E on F}}L_{\text{Joint to cm}}) + (-N_{\text{B on H}}L_{\text{Joint to H}}) = I_{\text{F}}\alpha_{\text{F}}$$

Solve and evaluate We now use the known values of the quantities to solve the problem:

$$a_{\text{B}y} = \frac{N_{\text{H on B}} - m_{\text{B}}g}{m_{\text{B}}} = \frac{20\text{ N} - (0.80\text{ kg})(9.8\text{ N/kg})}{(0.80\text{ kg})} = 15.2\text{ m/s}^2$$

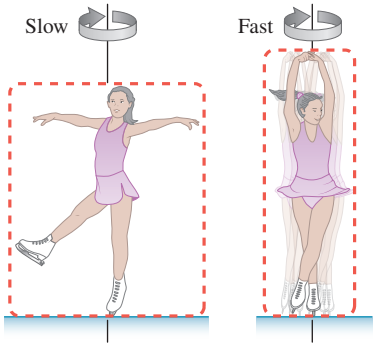
$$\alpha_{\text{F}} = \frac{a_{\text{B}y}}{r} = \frac{(15.2\text{ m/s}^2)}{(0.35\text{ m})} = +43.4\text{ rad/s}^2$$

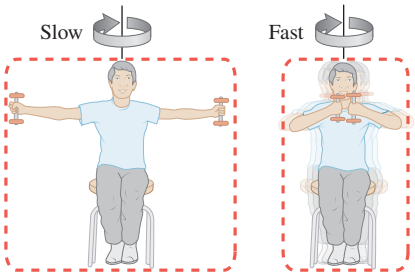
$$T_{\text{Bic on F}}(0.05\text{ m}) - [(1.5\text{ kg})(9.8\text{ N/kg})](0.16\text{ m}) - (20\text{ N})(0.35\text{ m}) = (0.061\text{ kg}\cdot\text{m}^2)(43.4\text{ rad/s}^2)$$

Solving the above equation, we find that $T_{\text{Bic on F}} = 240\text{ N} = 54\text{ lb}$, a reasonable magnitude for this force.

Try it yourself Determine the force that the woman's biceps exerts on her forearm during the initial instant of a vertical toss of a 100-g rubber ball if she is exerting a 10-N force on the ball.

Answer 430 N.





REVIEW QUESTION 9.3 How is Newton's second law for rotational motion similar to Newton's second law for translational motion? How is it different?

9.4 Rotational momentum

Earlier in this textbook (Chapters 6 and 7), we constructed powerful principles for momentum and energy that allowed us to analyze complex processes that involved translational motion. Is it possible to find analogous principles for the rotational (angular) momentum and rotational energy of extended bodies? Consider the experiments in Observational Experiment Table 9.6.

OBSERVATIONAL EXPERIMENT TABLE 9.6 Observations concerning rotational motion

VIDEO OET 9.6

Observational experiment		Analysis
Experiment 1. A figure skater initially spins slowly with a leg and two arms extended. Then she pulls her leg and arms close to her body, and her spinning rate increases dramatically.		*Initial situation:* Large rotational inertia I and small rotational speed ω. *Final situation:* Smaller rotational inertia I and larger rotational speed ω.
Experiment 2. A man sitting on a chair that can spin with little friction initially holds dumbbells far from his body and spins slowly. When he pulls the dumbbells close to his body, the spinning rate increases dramatically.		*Initial situation:* Large rotational inertia I and small rotational speed ω. *Final situation:* Smaller rotational inertia I and larger rotational speed ω.

Pattern

- There are no external forces exerted on either person—no torques.
- As the mass distribution of the system moves closer to the axis of rotation, the system's rotational inertia I decreases and the system's rotational speed ω increases (even though the net torque on the system is zero).

For each experiment in Table 9.6, the rotational inertia I of the spinning person decreased (the mass moved closer to the axis of rotation). Simultaneously, the rotational speed ω of the person increased. When I increases and ω decreases (or vice versa), $I\omega$ remains constant. We tentatively propose that when the rotational inertia I of an extended body in an isolated system decreases, its rotational speed ω increases, and vice versa.

Below we will continue to explore this idea quantitatively and then test it experimentally.

Rotational momentum is constant for an isolated system

Note that I is the rotational analog of the mass m of a point-like object and ω is the rotational analog of the translational velocity $\vec{v}$. The linear momentum of an object is the product of its mass m and its velocity $\vec{v}$. Let's propose that a turning object's **rotational momentum** L (analogous to linear momentum $\vec{p} = m\vec{v}$) is defined as

$$L = I\omega \tag{9.11}$$

In the chapter on linear momentum (Chapter 6) we derived a relationship [Eq. (6.4)] between the net force exerted on an object and the change in its linear momentum:

$$\Sigma\vec{F}(t_f - t_i) = \vec{p}_f - \vec{p}_i \tag{6.4}$$

where $\vec{p} = m\vec{v}$. Torque τ is analogous to force $\vec{F}$. Thus, using the analogy between rotational and translational motion, we write

$$\Sigma\tau(t_f - t_i) = L_f - L_i$$

where $L = I\omega$. If a system with one rotating body is isolated, then the external torque exerted on the object is zero. In such a case, the rotational momentum of the object does not change $(0 = L_f - L_i)$, and the object's rotational momentum is constant $(L_f = L_i)$, or

$$I_i\omega_i = I_f\omega_f$$

Note that this is consistent with our tentative qualitative rule. If the final value of one quantity (I or ω) increases for an isolated system, then the other quantity must decrease.

The similarity between the reasoning concerning rotational momentum of an isolated system and the reasoning we used to study linear momentum leads us to believe that we can use the bar chart representation to analyze rotational situations. We can also hypothesize that the change of rotational momentum of a system that is not isolated should be equal to the rotational equivalent of impulse. When a sum of forces $\Sigma\vec{F}$ is exerted on an system over a time interval Δt, the momentum of the system changes by the amount of $\Sigma\vec{F} \cdot \Delta t$. We can use the analogy between translational and rotational motion to say that **when a sum of torques $\Sigma\tau$ is exerted on a system over a time interval Δt, the rotational momentum of the system changes by the rotational impulse $\Sigma\tau\,\Delta t$.**

Rotational momentum and rotational impulse We now have a quantitative relation between rotational momentum $L = I\omega$ and rotational impulse.

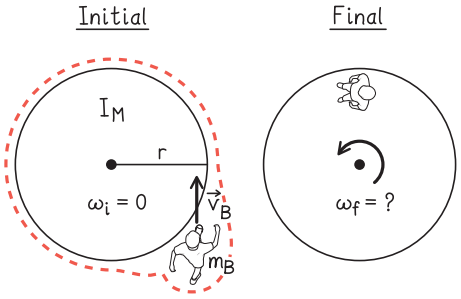
$$L_i + \Sigma\tau\Delta t = L_f \qquad (9.12)$$

The initial rotational momentum of a turning object plus the product of the net external torque exerted on the object and the time interval during which it is exerted equals the final rotational momentum of the object.

If the net torque that external objects exert on the turning object is zero, or if the torques add to zero, then the rotational momentum L of the turning object remains constant:

$$L_f = L_i \quad \text{or} \quad I_f\omega_f = I_i\omega_i \qquad (9.13)$$

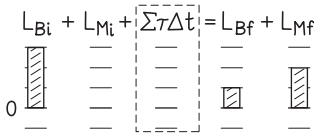
TIP Rotational momentum is sometimes called angular momentum.



To explain most of the applications of torque and rotational momentum in this book, we account for their directions using positive or negative signs:

- A torque is positive if it tends to rotate the object counterclockwise and negative if it tends to rotate the object clockwise about the axis of rotation.
- A body rotating counterclockwise has positive rotational momentum and one rotating clockwise has negative rotational momentum.

EXAMPLE 9.6 **Jumping on a merry-go-round**



A boy of mass m_B running at speed v_B steps tangentially onto the stationary circular platform of a merry-go-round that can rotate on a frictionless bearing about its central shaft. The radius of the platform is r and the rotational inertia of the merry-go-round is I_M. After stepping onto the platform, the boy stops moving with respect to the merry-go-round. Derive an expression for the rotational velocity of the merry-go-round ω_f after the boy steps on it.

Sketch and translate A sketch of the situation is shown at right. We choose the boy and the merry-go-round as the system and place the axis of rotation along the shaft of the merry-go-round. The initial state is just before the running boy steps onto the platform, and the final state is when the boy and the platform are rotating together.

Simplify and diagram We model the boy as a point-like object. The process in the problem is similar to an inelastic collision of two objects.

The vertical forces exerted on the system by Earth and the ground cannot exert torques on the system because they are parallel to the axis of rotation. At the moment when the boy steps onto the platform, the ground exerts a horizontal static friction force on the axis (preventing the merry-go-round from moving translationally), but because this force is exerted on the axis of the merry-go-round, it exerts no torque on the system. Therefore, the sum of all torques exerted on the system is zero, and the rotational momentum of the boy and the merry-go-round should remain constant. We can represent the process with a rotational momentum bar chart as shown in the figure below. The external impulse is zero because the torque is zero; thus the initial momentum of the boy is equal to the final momentum of the boy and merry-go-round together. Because the boy does not move with respect to the merry-go-round after that, and there are no external torques, the rotational momentum of the system and therefore the speed of the system are constant. Here we have a process in which the linear momentum of the system is not constant but the rotational momentum is.

Represent mathematically We use the bar chart to write the mathematical representation of the process: the initial and final rotational momenta of the system should be equal ($L_i = L_f$). Thus,

$$L_{Bi} + L_{Mi} = L_{B\text{ and }M\,f}$$

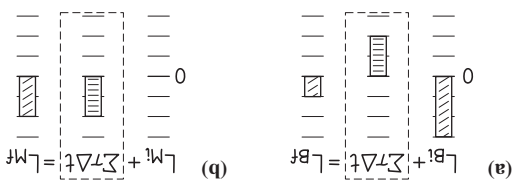
From the bar chart: $L_{Mi} = 0$. The initial rotational momentum of the boy with respect to the axis of rotation (which is outside his body), just before he jumps onto the merry-go-round, can be expressed as

$$L_{Bi} = I_B\omega_B = m_B r^2 \cdot \frac{v_B}{r} = m_B v_B r$$

In the final state, the boy and the merry-go-round rotate as one rigid body. Therefore, the final rotational momentum of the system can be expressed as $L_{B\text{ and }M\,f} = (m_B r^2 + I_M)\omega_f$.

Solve and evaluate Combining the equations above, we get

$$m_B v_B r = (m_B r^2 + I_M)\omega_f$$



and finally

$$\omega_f = \frac{m_B v_B r}{m_B r^2 + I_M}$$

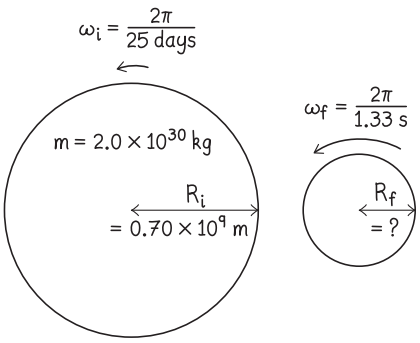
To evaluate the expression we need to examine it for extreme cases. The expression predicts that the faster the boy runs, the larger the final rotational velocity of the merry-go-round—this makes sense. The larger the rotational inertia of the merry-go-round, the smaller the final rotational velocity—this prediction makes sense, too. Checking the units for ω_f in our expression, we get $\frac{\text{kg} \times \text{m/s} \times \text{m}}{\text{kg} \times \text{m}^2} = \frac{1}{\text{s}}$. The units for rotational velocity are rad/s, but as we noted earlier, radians have no dimension and so our unit analysis confirms the expression for ω_f.

Try it yourself In the example, we chose the boy and the merry-go-round as the system. How will the rotational momentum bar charts change if we choose (a) the boy as the system or (b) the merry-go-round as the system? Draw these two bar charts.

Answer

Rotational momentum of a shrinking object

At the beginning of the chapter, we described the discovery of pulsars, astronomical objects that rotate very quickly and emit repetitive radio signals with a very small time interval between them. The signals from the first discovered pulsar had a period of approximately 1.33 s. Astronomers could not explain at first how pulsars could rotate so rapidly. Most stars, including our Sun, rotate very much the way Earth does, usually taking several days to complete one rotation (about a month for our Sun).



However, as a star's core collapses and its mass moves closer to the axis of rotation, its rotational velocity increases because its rotational momentum is constant (assuming the star does not interact with any other objects). How much does a star need to shrink so that its period of rotation becomes seconds instead of days?

TIP Remember that the notation for period is T. Do not confuse this with T also used for the tension force.

EXAMPLE 9.7 **A pulsar**

Imagine that our Sun ran out of nuclear fuel and collapsed. What would its radius have to be in order for its period of rotation to be the same as the first discovered pulsar described above? The Sun's current period of rotation is 25 days.

Sketch and translate First, sketch the process. The Sun is the system. We can convert the present period of rotation of the Sun into seconds ($T_i = 25$ days $= 2.16 \times 10^6$ s). Its mass is $m = 2.0 \times 10^{30}$ kg and its radius is $R_i = 0.70 \times 10^9$ m. After the Sun collapses, its period of rotation will be $T_f = 1.33$ s. What will be its radius?

(CONTINUED)

Simplify and diagram Assume that the Sun is a sphere with its mass distributed uniformly. Assume also that it does not lose any mass as it collapses.

Represent mathematically Now, apply the principle of rotational momentum conservation (Eq. 9.13) to the Sun's collapse:

$$I_i\omega_i = I_f\omega_f$$

From Table 9.5 we find that the rotational inertia of a sphere rotating around an axis passing through its center is

$$I = \tfrac{2}{5}mR^2$$

The rotational velocity of an object is

$$\omega = \frac{\Delta\theta}{\Delta t} = \frac{2\pi}{T}$$

where T is the period for one rotation. Combining the above three equations, we get

$$\left(\tfrac{2}{5}mR_i^2\right)\frac{2\pi}{T_i} = \left(\tfrac{2}{5}mR_f^2\right)\frac{2\pi}{T_f}$$

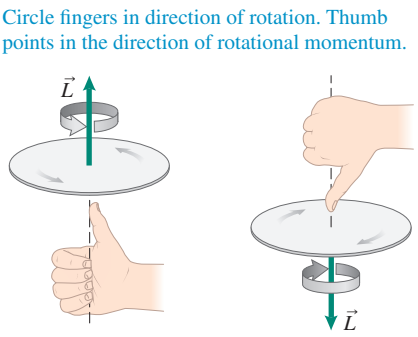
Dividing by the $2/5$, 2π, and m on each side of the equation, we get

$$\frac{R_i^2}{T_i} = \frac{R_f^2}{T_f}$$

Solve and evaluate Multiply both sides of the above by T_f and take the square root:

$$R_f = \sqrt{\frac{R_i^2 T_f}{T_i}}$$
$$= \sqrt{\frac{(0.70 \times 10^9\ \text{m})^2(1.33\ \text{s})}{2.16 \times 10^6\ \text{s}}}$$
$$= 5.5 \times 10^5\ \text{m} = 550\ \text{km}$$

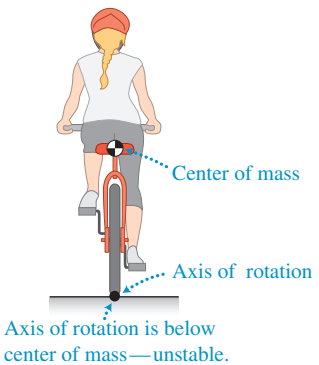
Although this is much smaller than the radius of Earth, models of stellar evolution actually do predict that the Sun's core will eventually shrink to this size and possibly smaller.



Try it yourself When massive stars explode, the collapse can shrink their radii to about 10 km. What would be the period of rotation of such a star if it originally had a mass twice the mass of the Sun, a radius that was 1.3 times the Sun's radius, and the same initial period of rotation as the Sun (25 days)?

Answer 2.6×10^{-4} s.

Vector nature of torque, rotational velocity, and rotational momentum

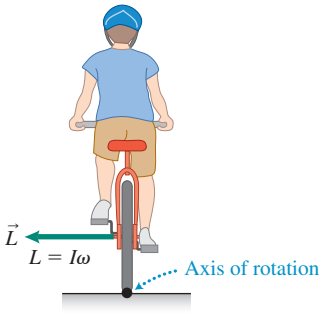


So far, we have treated torque, rotational velocity, and rotational momentum as scalar quantities, but at the same time we assigned signs to them reflecting CW or CCW direction of rotation. Thus the value of these quantities depends on the direction of rotation. In fact, all of those quantities are vector quantities, but for most applications in this chapter we do not need to treat them as such. However, there are a few applications for which the vector nature of torque, rotational velocity, and rotational momentum is important. The vector direction of both rotational velocity and rotational momentum can be determined using **a right-hand rule**.

FIGURE 9.12 Using the right-hand rule to determine the direction of an object's rotational momentum $\vec{L}$.

Right-hand rule for determining the direction of torque, rotational velocity, and rotational momentum Curl the four fingers of your right hand in the direction of rotation of the turning object. Your thumb, held perpendicular to the fingers, then points in the direction of both the object's rotational velocity and rotational momentum (**Figure 9.12**). To determine the **vector direction** of the torque that a force produces on an object (as opposed to the clockwise/counterclockwise way of describing it) about an axis of rotation, first imagine that the object is at rest and that the torque you are interested in is the only torque exerted on the object. Next, curl the fingers of your right hand in the direction that the torque would make the object rotate. Your thumb, held perpendicular to the fingers, shows the direction of this torque.

FIGURE 9.13 A bicycle that is not moving is in unstable equilibrium.



Bicycling We can use the vector nature of torque and rotational momentum to understand why a bicycle is much more stable when moving fast—especially if the bicycle has massive tires. Consider an axis of rotation parallel to the ground that passes through the two contact points of the tires with the ground. This axis of rotation is below the center of mass of the stationary bike—an unstable equilibrium (**Figure 9.13**). When the bicycle is moving quickly, the rotating tires (and therefore the bicycle + rider system) have considerable rotational momentum, which will change only when an unbalanced torque

is exerted on the system. When a bicycle is moving on a smooth road, the rotational velocity and the rotational momentum vectors are perpendicular to the plane of rotation of the bike tires (**Figure 9.14**), and they are large due to the rapid rotation of the tires.

When the bike + rider system is balanced, the gravitational force exerted by Earth on the system produces no torque since that force points directly at the axis of rotation. If the rider's balance shifts a bit, or the wind blows, or the road is uneven, the system will start tilting. As a result, the gravitational force exerted on the system will produce a torque. However, since the rotational momentum of the system is large, this torque does not change its direction by much right away, but it takes only several tenths of a second for the torque to change the rotational momentum significantly. This is enough time for an experienced rider to make corrections to rebalance the system. The faster the person is riding the bike, the greater the rotational momentum of the system and the more easily the rider can keep the system balanced.

FIGURE 9.14 Rotating bicycle tires have rotational momentum that stabilizes the bicycle.

Gyroscopes Guidance systems for spaceships rely on the constancy of rotational momentum in isolated systems to help them maintain their chosen course. Once the ship is pointed in the desired direction, one or more heavy gyroscopes start rotating. The gyroscope is a wheel whose axis of rotation keeps the ship oriented in the chosen direction. The gyroscope is similar to the rotating bicycle tires that help keep a rider upright without tipping or changing direction. Gyroscopes are also used in cameras to prevent them from vibrating or moving while the camera lens is open.

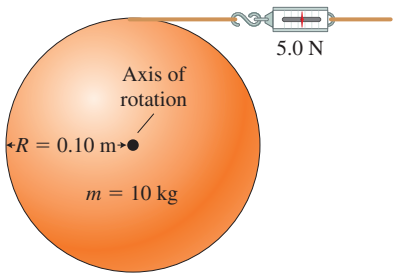
REVIEW QUESTION 9.4 After a playground merry-go-round is set in motion, its rotational speed decreases noticeably if another person jumps on it. However, if a person riding the merry-go-round steps off, the rotational speed seems not to change at all. Explain.

9.5 Rotational kinetic energy

We are familiar with the kinetic energy $(1/2)mv^2$ of a single particle moving along a straight line or in a circle. It would be useful to calculate the kinetic energy of a rotating body—like Earth. Doing so would allow us to use the work-energy approach to solving problems involving rotation. Let's start by deriving an expression for the **rotational kinetic energy** of a single particle of mass m moving in a circle of radius r at speed v. According to the kinematics in Section 9.1, its linear speed v and rotational speed ω are related:

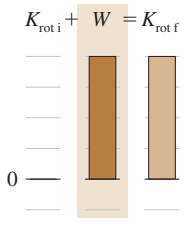
$$v = r\omega$$

Thus, the kinetic energy of this particle moving in a circle can be written as



$$K_{\text{rot}} = \tfrac{1}{2}mv^2 = \tfrac{1}{2}m(r\omega)^2 = \tfrac{1}{2}(mr^2)\omega^2 = \tfrac{1}{2}I\omega^2$$

where $I = mr^2$ is the rotational inertia of a particle moving a distance r from the center of its circular path. The expression for the translational kinetic energy $(1/2)mv^2$ of a particle is similar to the rotational version, which involves the product of a mass-like term I and the square of a speed-like term ω. Can we use the expression $\frac{1}{2}I\omega^2$ for the rotational kinetic energy of a rotating rigid body?



To test this idea, consider a solid sphere of known radius R and mass m that can rotate freely on an axis. We wrap a string around the sphere and pull the string with a force probe exerting a constant force of a known magnitude so that the sphere starting at rest completes 5.0 revolutions (**Figure 9.15a**). After we stop pulling, we measure the rotational speed ω of the sphere. But before measuring it, we predict its value using this expression for rotational kinetic energy. If we choose the sphere as the system, the string is the only external object that exerts a force that causes a nonzero torque on the sphere. This string force does work, which changes the sphere's kinetic energy from zero to some new value (Figure 9.15b). Thus, the initial rotational kinetic energy of

FIGURE 9.15 A string pulls a solid sphere (top view).

(a)

(b) Work done by the string causes the rotational kinetic energy of the sphere to increase.

the sphere (zero) plus the work done by the string on the sphere during these five turns equals the final rotational kinetic energy of the sphere:

$$K_{\text{rot i}} + W = K_{\text{rot f}}$$

The string pulls parallel to the displacement of the edge of the sphere during the entire time. We can use the expression for the rotational kinetic energy under test to predict the magnitude of the final rotational speed:

$$0 + F_{\text{String on Sphere}}(5 \cdot 2\pi R)\cos 0 = \tfrac{1}{2} I\omega^2$$

where $5 \cdot 2\pi R$ is the distance the string is pulled—five circumferences of the sphere. The above leads to a prediction of the final rotational speed:

$$\omega_{\text{f}} = \sqrt{\frac{F_{\text{String on Sphere}} \cdot 20\pi R}{I}}$$

From Table 9.5 we know that the rotational inertia of a solid sphere of radius R and mass m is $I = (2/5)mR^2$ (the axis passes through the center of the sphere); in our sphere, $m = 10$ kg and $R = 0.10$ m. Thus, the rotational inertia is

$$I = (2/5)mR^2 = (2/5)(10\text{ kg})(0.10\text{ m})^2 = 0.040\text{ kg}\cdot\text{m}^2$$

We pull the string so that it exerts a 5.0-N force on the edge of the sphere. Thus, the sphere's final speed should be

$$\omega_{\text{f}} = \sqrt{\frac{(5.0\text{ N})(20\,\pi)(0.10\text{ m})}{(0.040\text{ kg}\cdot\text{m}^2)}} = \left(28\,\frac{\text{rad}}{\text{s}}\right)\left(\frac{1\text{ rev}}{2\pi\text{ rad}}\right) = 4.5\,\frac{\text{rev}}{\text{s}}$$

When we measure the final angular velocity, it is about 4.5 rev/s.

We can apply our new understanding of rotational kinetic energy to predict the outcome of the experiment shown in **Figure 9.16a**. A solid cylinder and a hoop of the same radius and mass start rolling at the top of an inclined plane. Which object reaches the bottom of the plane first? What is the ratio of their speeds at the bottom?

Both Earth-object systems start with the same gravitational potential energy. As they roll, both acquire translational and rotational kinetic energies. We can represent the process in a work-energy bar chart (Figure 9.16b). The bar chart helps us construct a mathematical description:

$$mgy_{\text{i}} = \tfrac{1}{2}mv_{\text{f}}^2 + \tfrac{1}{2}I\omega_{\text{f}}^2$$

Since the objects are rolling without skidding, the rotational speed ω and translational speed v are related as $\omega = v/r$. We substitute this into the above energy equation and then rearrange:

$$mgy_{\text{i}} = \tfrac{1}{2}\left(m + \frac{I}{r^2}\right)v_{\text{f}}^2$$

$$\Rightarrow v_{\text{f}} = \sqrt{\frac{2mgy_{\text{i}}}{\left(m + \dfrac{I}{r^2}\right)}}$$

This expression for v_{f} suggests that at the bottom of the inclined plane, the object with greater rotational inertia I will have the smaller translational speed v_{f}. Using the information in Table 9.5, we have $I_{\text{cylinder}} = \frac{1}{2}mr^2$ and $I_{\text{hoop}} = mr^2$. Thus $I_{\text{hoop}} > I_{\text{cylinder}}$, giving the conclusion that the cylinder should reach the bottom first.

We can now find the ratio of their final speeds. We insert the expressions for the rotational inertia of the solid cylinder and of the hoop to find their final speeds. For the cylinder, $v_{\text{f}} = \sqrt{\frac{4}{3}gy_{\text{i}}}$, and for the hoop, $v_{\text{f}} = \sqrt{gy_{\text{i}}}$. The ratio of their final speeds is $\sqrt{\frac{4}{3}}$, with the cylinder moving faster. When we perform the experiment (see the video), we see that the cylinder reaches the bottom of the plane first.

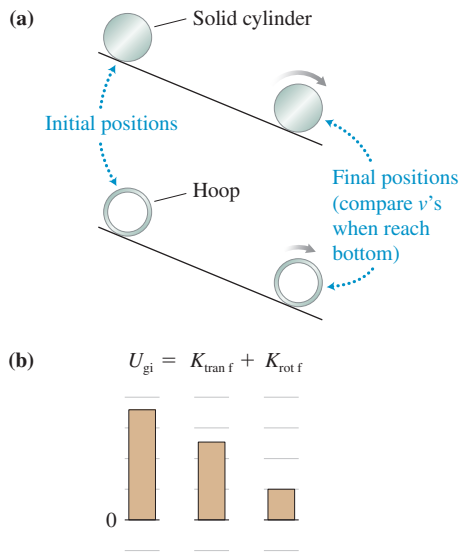


FIGURE 9.16 A race between a hoop and a cylinder of the same mass.

VIDEO 9.1

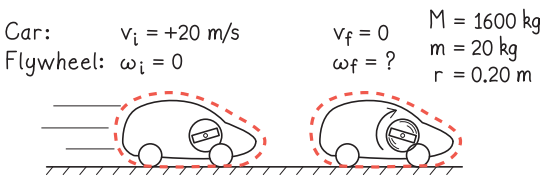
This is the second testing experiment involving rotational kinetic energy in which the outcome matched the prediction. Given this support for our prediction and the lack of counterevidence, we will use this mathematical expression for a rigid body's rotational kinetic energy.

Rotational kinetic energy The rotational kinetic energy of an object with rotational inertia I turning with rotational speed ω is

$$K_{\text{rot}} = \tfrac{1}{2} I\omega^2 \tag{9.14}$$

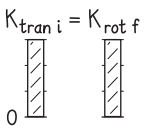
TIP When you encounter a new physical quantity, always check whether its units make sense. In this particular case, the units for I are $\text{kg}\cdot\text{m}^2$ and the units for ω^2 are $1/\text{s}^2$. Thus, the unit for kinetic energy is $\text{kg}\cdot\text{m}^2/\text{s}^2 = (\text{kg}\cdot\text{m}/\text{s}^2)\,\text{m} = \text{N}\cdot\text{m} = \text{J}$, the correct unit for energy.

Flywheels for storing and providing energy



You stop your car at a stoplight. Before stopping, the car had considerable kinetic energy; after stopping, the kinetic energy is zero. It has been converted to internal energy due to friction in the brake pads. Unfortunately, this thermal energy cannot easily be converted back into a form that is useful. Is there a way to convert that translational kinetic energy into some other form of energy that would help the car regain translational kinetic energy when the light turns green?

Efforts are under way to use the rotational kinetic energy of flywheels (rotating disks) for this purpose. Instead of rubbing a brake pad against the wheel and slowing it down, the braking system would, through a system of gears or through an electric generator, convert the car's translational kinetic energy into the rotational kinetic energy of a flywheel. As the car's translational speed decreases, the flywheel's rotational speed increases. This rotational kinetic energy could then be used to help the car start moving, rather than relying entirely on the chemical potential energy of gasoline.



EXAMPLE 9.8 Flywheel rotational speed

A 1600-kg car traveling at 20 m/s approaches a stop sign. If it could transfer all of its translational kinetic energy to a 0.20-m-radius, 20-kg flywheel while stopping, what rotational speed would the flywheel acquire?

Sketch and translate A sketch of the situation is shown below. The system of interest is the car, including the flywheel.

Simplify and diagram The process is represented at right with a bar chart. The initial energy of the system is the car's translational kinetic energy; the final energy is the flywheel's rotational kinetic energy. Braking converts car's initial kinetic energy into the flywheel's rotational energy, which is saved for future use. Assume that the flywheel is a solid disk with rotational inertia of $(1/2)mr^2$ (see Table 9.5).

Represent mathematically Use the bar chart to help construct an energy conservation equation:

$$K_{\text{tran i}} = K_{\text{rot f}}$$

$$\tfrac{1}{2}Mv_i^2 = \tfrac{1}{2}I\omega_f^2$$

Multiplying both sides of the equation by 2 and dividing by I, we get

$$\omega_f^2 = \frac{Mv_i^2}{I}$$

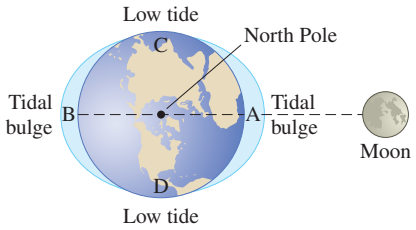
The rotational inertia of the disk (a solid cylinder) is $I_{\text{cylinder}} = (1/2)mr^2$. Thus,

$$\omega_f^2 = \frac{Mv_i^2}{I} = \frac{Mv_i^2}{\frac{1}{2}mr^2} = \frac{2Mv_i^2}{mr^2}$$

Solve and evaluate To find the rotational speed, take the square root of both sides of the above equation:

$$\omega_f = \frac{v_i}{r}\sqrt{\frac{2M}{m}} = \frac{20\ \text{m/s}}{0.20\ \text{m}}\sqrt{\frac{2(1600\ \text{kg})}{(20\ \text{kg})}} = 1300\ \text{rad/s}$$

$$= 200\ \text{rev/s} = 12{,}000\ \text{rpm}$$



Try it yourself Could you store more energy in a rotating hoop or in a rotating solid cylinder, assuming they have the same mass, radius, and rotational speed?

Answer The hoop has a greater rotational inertia and therefore would have a greater rotational kinetic energy at the same rotational speed.

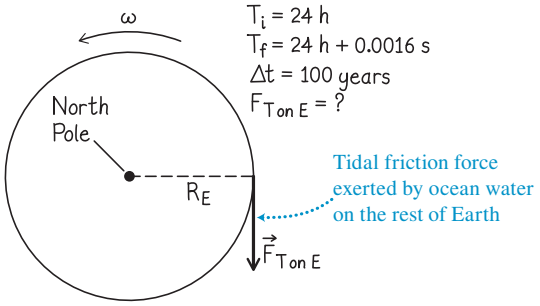
REVIEW QUESTION 9.5 Will a can of watery chicken noodle soup roll slower or faster down an inclined plane than an equal-mass can of thick English clam chowder?

9.6 Tides and Earth's day

FIGURE 9.17 The ocean bulges on both sides of Earth along a line toward the Moon.

The level of the ocean rises and falls by an average of 1 m twice each day, a phenomenon known as the tides. Many scientists, including Galileo, tried to explain this phenomenon and suspected that the Moon was a part of the answer. Isaac Newton was the first to explain how the motion of the Moon actually creates tides. He noted that at any moment, different parts of Earth's surface are at different distances from the Moon and that the distance from a given location on Earth to the Moon varied as Earth rotated. As illustrated in **Figure 9.17**, point A is closer to the Moon than the center of Earth or point B are, and therefore the gravitational force exerted by the Moon on point A is greater than the gravitational force exerted on point B. Due to the difference in forces, Earth elongates along the line connecting its center to the Moon's. This makes water rise to a high tide at point A and surprisingly also at B. The water "sags" a little at points C and D, forming low tides at those locations. When the Sun is aligned with the Moon and Earth, the bulging is especially pronounced.

As the solid Earth rotates beneath the tidal bulges, it attempts to drag the bulges with it. A large amount of friction is produced, which converts the rotational kinetic energy of Earth into internal energy. The time interval needed for Earth to complete one turn on its axis increases by 0.0016 s every 100 years. In other words, the Earth day is slowly getting longer. In a very long time, Earth will stop turning relative to the Moon and an unmoving tidal bulge will face toward and away from the Moon. This "tidal locking" has already occurred on the Moon (although it is solid, the same principle applies), which is why on Earth we only see one side of the Moon. It rotates around its axis with the same period as it moves around Earth.



Let's use our new understanding of rotational dynamics to estimate the friction force the tides exert on Earth, causing Earth's rotation rate to decrease.

EXAMPLE 9.9 **Tides slow Earth's rotation**

Estimate the effective tidal friction force exerted by ocean water on Earth that causes a 0.0016-s increase in Earth's rotation time every 100 years.

Sketch and translate The situation is already sketched in Figure 9.17. The solid Earth is the system; the water covering most of its surface is considered an external object for this estimate. Earth rotates counterclockwise, taking 24 hours for one revolution (one period), as seen looking down on the North Pole. Remember that when an object rotates counterclockwise, its angular velocity is considered to be positive. Since Earth's rotation is gradually slowing, the tidal friction force is producing a negative torque, opposite the positive sign of the rotational velocity. We need to find the magnitude of the force that would increase the time of one revolution by 0.0016 s in 100 years.

Simplify and diagram Assume that the solid Earth is a sphere covered uniformly with water on its surface. Assume also that the frictional force exerted by the water on Earth is constant in magnitude and exerted at the equator. The force exerted by the tidal bulge on Earth produces a torque that opposes Earth's rotation.

Represent mathematically To estimate the friction force exerted by the oceans on Earth, we need to determine the torque produced by that force. We can use the rotational form of Newton's second law if we can determine the rotational inertia of Earth and its rotational acceleration. The rotational acceleration of Earth is

$$\alpha = \frac{\Delta\omega}{\Delta t} = \frac{\omega_f - \omega_i}{\Delta t} = \frac{\left(+\frac{2\pi}{T_f}\right) - \left(+\frac{2\pi}{T_i}\right)}{\Delta t}$$

$$= \frac{2\pi}{\Delta t}\left(\frac{1}{T_f} - \frac{1}{T_i}\right)$$

where $T_i = 24\text{ h}\left(\frac{3600\text{ s}}{1\text{ h}}\right) = 86{,}400\text{ s}$, $T_f = T_i + \Delta T =$ $86{,}400\text{ s} + 0.0016\text{ s}$, and $\Delta t = 100\text{ years}\left(\frac{365\text{ days}}{1\text{ year}}\right)\left(\frac{86{,}400\text{ s}}{1\text{ day}}\right)$ $= 3.15 \times 10^9\text{ s}$.

Because T_f and T_i are so close, your calculator will likely evaluate the rotational acceleration of Earth to be zero. To deal with this, we put the equation into another form.

$$\alpha = \frac{2\pi}{\Delta t}\left(\frac{1}{T_f} - \frac{1}{T_i}\right) = \frac{2\pi}{\Delta t}\left(\frac{T_i - T_f}{T_i T_f}\right)$$
$$= \frac{2\pi}{\Delta t}\left(\frac{-\Delta T}{T_i(T_i + \Delta T)}\right) = \frac{2\pi}{\Delta t}\left(\frac{-\Delta T}{T_i^2 + T_i\,\Delta T}\right)$$

Now look at the two terms in the denominator, T_i^2 and $T_i\,\Delta T$. Because ΔT is so small, the second term is much less than the first term. This means the second term can be dropped without affecting the result in any significant way. Thus,

$$\alpha = -\frac{2\pi\,\Delta T}{\Delta t T_i^2}$$

We can use the rotational form of Newton's second law to get an alternative expression for Earth's rotational acceleration:

$$\alpha = \frac{1}{I}\Sigma\tau = \frac{1}{\frac{2}{5}mR_E^2}\left(F_{T\text{ on }E}R_E \sin 90°\right)$$

The R_E in the numerator is the distance from the axis of rotation to the surface where the friction force is exerted, the radius of Earth. The R_E in the denominator is also the radius of Earth.

$$\alpha = \frac{1}{\frac{2}{5}mR_E^2}\left(F_{T\text{ on }E}R_E \sin 90°\right) = \frac{5F_{T\text{ on }E}}{2mR_E}$$

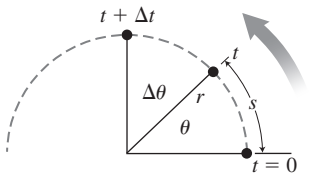
Setting the two expressions for the magnitude of the rotational acceleration equal to each other, we get

$$\frac{2\pi\,\Delta T}{\Delta t T_i^2} = \frac{5F_{T\text{ on }E}}{2mR_E}$$

Solve and evaluate Solve the previous equation for the force of the tides on Earth:

$$F_{T\text{ on }E} = \frac{4\pi mR_E\,\Delta T}{5\,\Delta t T_i^2}$$
$$= \frac{4\pi(5.97 \times 10^{24}\text{ kg})(6.38 \times 10^6\text{ m})(0.0016\text{ s})}{5(3.15 \times 10^9\text{s})(86{,}400\text{ s})^2}$$
$$= 6.5 \times 10^9\text{ N}$$

The magnitude of this friction force seems big, and it is. But when exerted on an object of such large mass $(5.97 \times 10^{24}\text{ kg})$, the effect is extremely tiny. By comparison, the gravitational force that the Sun exerts on Earth is $3.5 \times 10^{22}\text{ N}$.



Try it yourself Estimate the time interval in years that it will take for Earth's rotation to change from 24 hours to 27 days.

Answer Using Eq. (9.3), we find $t = (\omega - \omega_0)/\alpha \approx -\omega_0/\alpha =$ $(-7 \times 10^{-5}\text{ rad/s})/(-4 \times 10^{-22}\text{ rad/s}^2) = 2 \times 10^{17}\text{ s}$, almost 10 billion years.

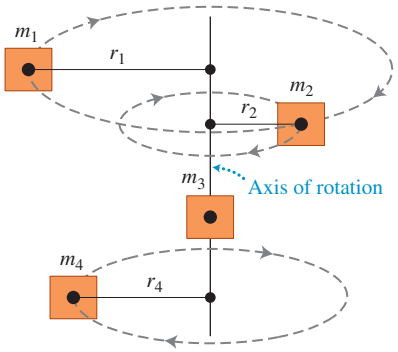
REVIEW QUESTION 9.6 How can you explain the increasing length of a day on Earth?

Summary

Rotational kinematics The rotational motion of a rigid body can be described using quantities similar to those for translational motion—rotational position θ, rotational velocity ω, and rotational acceleration α. (Section 9.1)

- Rotational position (in radians)

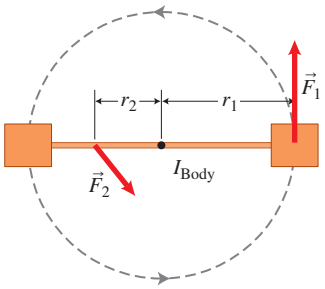
$$\theta = s/r \qquad \text{Eq. (9.1)}$$



- Rotational velocity (in rad/s)

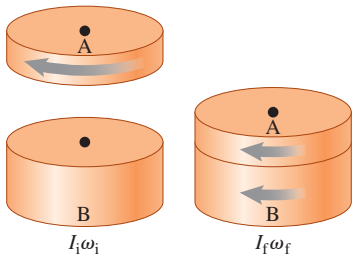
$$\omega = \Delta\theta/\Delta t \qquad \text{Eq. (9.2)}$$

- Rotational acceleration (in rad/s^2)

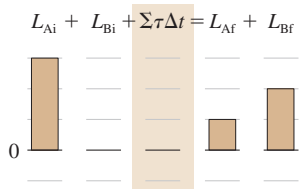


$$\alpha = \Delta\omega/\Delta t \qquad \text{Eq. (9.3)}$$

Rotational inertia I is the physical quantity equal to the sum of the mr^2 terms for each part of an object and depends on the distribution of mass relative to an axis of rotation. (Sections 9.2 and 9.3)



$$I = \Sigma mr^2 \qquad \text{Eq. (9.9)}$$



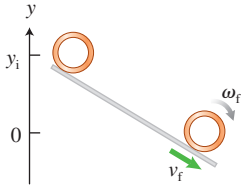
Rotational dynamics A rigid body's rotational acceleration equals the net torque produced by forces exerted on the body divided by its rotational inertia. (Section 9.3)

$$\alpha = \frac{1}{I}\Sigma\tau \qquad \text{Eq. (9.10)}$$

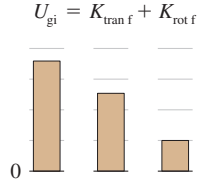
Rotational momentum L is the product of the rotational inertia I of an object and its rotational velocity ω, positive for counterclockwise rotation and negative for clockwise rotation. For an isolated system (zero net torque exerted on it), the rotational momentum of the system is constant. (Section 9.4)

$$L = I\omega \qquad \text{Eq. (9.11)}$$

Translational motion equivalent:



$$\vec{p} = m\vec{v} \qquad \text{Eq. (6.1)}$$



For isolated system,

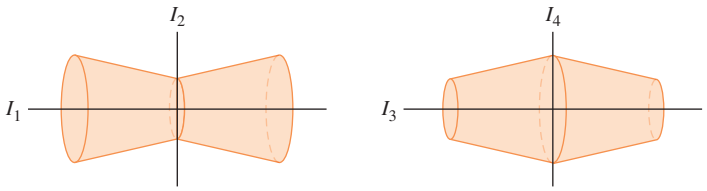
$$I_i\omega_i = I_f\omega_f \qquad \text{Eq. (9.13)}$$

For nonisolated systems, rotational impulse $\Sigma\tau\,\Delta t$ is nonzero.

Rotational kinetic energy K_{rot} of a rigid body is energy due to the rotation of the object about a particular axis. This is another form of kinetic energy that is included in the work-energy principle. (Section 9.5)

$$K_{\text{rot}} = \tfrac{1}{2}I\omega^2 \qquad \text{Eq. (9.14)}$$

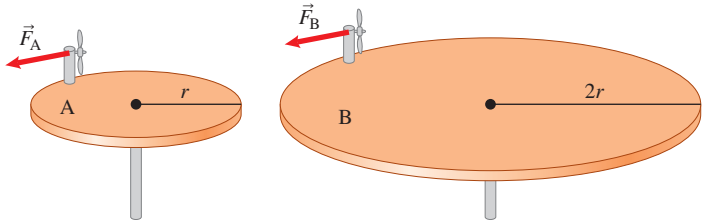
Translational motion equivalent:



$$K_{\text{tran}} = \tfrac{1}{2}mv^2 \qquad \text{Eq. (7.5)}$$

Questions

Multiple Choice Questions



1. Is it easier to open a door that is made of a solid piece of wood or a door of the same mass made of light fiber with a steel frame?
   (a) Wooden door
   (b) Fiber door with a steel frame
   (c) The same difficulty
   (d) Not enough information to answer
2. You push a child on a swing. Why doesn't the child continue in a vertical loop over the top of the swing?
   (a) The torque of the force that Earth exerts on the child pulls him back.
   (b) The swing does not have enough kinetic energy when at the bottom.
   (c) The swing does not have enough rotational momentum.
   (d) All of the above are correct.
3. In terms of the torque needed to rotate your leg as you run, would it be better to have a long calf and short thigh, or vice versa?
   (a) Long calf and short thigh
   (b) Short calf and long thigh
   (c) Does not matter
4. Suppose that two bicycles have equal overall mass, but one has thin lightweight tires while the other has heavier tires made of the same material. Why is the bicycle with thin tires easier to accelerate?
   (a) Thin tires have less area of contact with the road.
   (b) With thin tires, less mass is distributed at the rims.
   (c) With thin tires, you don't have to raise the large mass of the tire at the bottom to the top.
5. When riding a 10-speed bicycle up a hill, a cyclist shifts the chain to a larger-diameter gear attached to the back wheel. What must be true when the cyclist shifts to a larger gear?
   (a) The torque exerted by the chain on the gear is larger.
   (b) The force exerted by the chain on the gear is larger.
   (c) The cyclist pedals more frequently to travel the same distance.
   (d) Both a and c are correct.
6. The objects in **Figure Q9.6** are made of two identical paper cups glued together. Rank the rotational inertias I_1, I_2, I_3, and I_4 about the indicated axes using the signs $=$, $>$, and $<$. Explain.

FIGURE Q9.6

7. Select all the pairs below in which the two physical quantities have the same units.
   (a) Rotational velocity and translational velocity
   (b) Rotational kinetic energy and translational kinetic energy
   (c) Linear momentum and rotational momentum
   (d) Work and torque
   (e) Power and energy
   (f) Impulse (that changes linear momentum) and rotational impulse
8. If you turn on a coffee grinding machine sitting on a smooth tabletop, what do you expect it to do?
   (a) Start rotating in the same direction as the blades rotate
   (b) Start rotating in the direction opposite the blade rotation
   (c) Grind the coffee without any rotation of the machine
9. A bowling ball is rolling without skidding down an incline. While accelerating down the incline, the ratio of translational kinetic energy to rotational kinetic energy of the ball
   (a) remains constant and equal to about 0.4.
   (b) remains constant and equal to about 2.5.
   (c) remains constant; the value depends on the radius of the ball.
   (d) decreases.
   (e) increases.
10. The Mississippi River carries sediment from higher latitudes toward the equator. How does this affect the length of the day?
    (a) Increases the day
    (b) Decreases the day
    (c) Does not affect the day
    (d) There is no relation between the mass distribution and the length of the day.
11. Two disks are cut from the same uniform board. The radius of disk B is twice the radius of the disk A. The disks can rotate around axes with negligible friction. Two very light battery-powered fans are attached to the disks, as shown in **Figure Q9.11**. When switched on, the fans exert equal forces on the disks. Which of the following correctly compares and explains the rotational accelerations of the disks after the fans are switched on?
    (a) $\alpha_A = 4\alpha_B$ because $F_B = F_A$ and $m_B = 4m_A$.
    (b) $\alpha_A = \alpha_B$ because $\tau_B = 2\tau_A$ and $I_B = 2I_A$.
    (c) $\alpha_A = 2\alpha_B$ because $\tau_B = 2\tau_A$ and $I_B = 4I_A$.
    (d) $\alpha_A = 4\alpha_B$ because $\tau_B = 2\tau_A$ and $I_B = 8I_A$.
    (e) $\alpha_A = 8\alpha_B$ because $\tau_B = 2\tau_A$ and $I_B = 16I_A$.

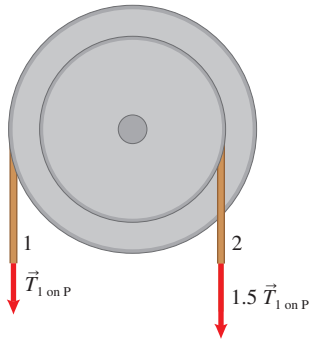
FIGURE Q9.11

Conceptual Questions

12. Explain your choices for Questions 1–11 (your instructor will choose which ones).
13. A spinning raw egg, if stopped momentarily and then released by the fingers, will resume spinning. Explain. Will this happen with a hard-boiled egg? Explain.
14. Compare the magnitude of Earth's rotational momentum about its axis to that of the Moon about Earth. The tides exert a torque on Earth and the Moon so that eventually they will rotate with the same period. The object with the greater rotational momentum will experience the smaller percent change in the period of rotation. Will Earth's solar day increase more than the Moon's period of rotation decreases? Explain.
15. You lay a pencil on a smooth desk (ignore sliding friction). You push the pencil, exerting a constant force first directly at its center of mass and then close to the tip of the pencil. In both cases, the force is exerted perpendicular to the body of the pencil. If the forces that you exert on the pencil are exactly the same in magnitude and direction, in which case is the translational acceleration of the pencil greater in magnitude?
16. If you watch the dive of an Olympic diver, you note that she continues to rotate after leaving the board. However, her center of mass follows a parabolic curve. Explain why.
17. Explain why you do not tip over when riding a bicycle but do tip when stationary at a stoplight.
18. Sometimes a door is not attached properly and it will open by itself or close by itself. But it will never do both. Why?
19. Why do tightrope walkers carry long, heavy bars?

Problems

Below, BIO indicates a problem with a biological or medical focus. Problems labeled EST ask you to estimate the answer to a quantitative problem rather than derive a specific answer. Asterisks indicate the level of difficulty of the problem. Problems with no * are considered to be the least difficult. A single * marks moderately difficult problems. Two ** indicate more difficult problems.



9.1 Rotational kinematics

1. The sweeping second hand on your wall clock is 20 cm long. What is (a) the rotational speed of the second hand, (b) the translational speed of the tip of the second hand, and (c) the rotational acceleration of the second hand? Assume the second hand moves smoothly.
2. You find an old record player in your attic. The turntable has two readings: 33 rpm and 45 rpm. What do they mean? Express these quantities in different units.
3. * Consider again the turntable described in the last problem. Determine the magnitudes of the rotational acceleration in each of the following situations. Indicate the assumptions you made for each case. (a) When on and rotating at 33 rpm, it is turned off and slows and stops in 60 s. (b) When off and you push the play button, the turntable attains a speed of 33 rpm in 15 s. (c) You switch the turntable from 33 rpm to 45 rpm, and it takes about 2.0 s for the speed to change. (d) In the situation in part (c), what is the magnitude of the average tangential acceleration of a point on the turntable that is 15 cm from the axis of rotation?
4. You step on the gas pedal in your car, and the car engine's rotational speed changes from 1200 rpm to 3000 rpm in 3.0 s. What is the engine's average rotational acceleration?
5. You pull your car into your driveway and stop. The drive shaft of your car engine, initially rotating at 2400 rpm, slows with a constant rotational acceleration of magnitude 30 rad/s^2. How long does it take for the drive shaft to stop turning?
6. An old wheat-grinding wheel in a museum actually works. The sign on the wall says that the wheel has a rotational acceleration of 190 rad/s^2 as its spinning rotational speed increases from zero to 1800 rpm. How long does it take the wheel to attain this rotational speed?
7. **Centrifuge** A centrifuge at the same museum is used to separate seeds of different sizes. The average rotational acceleration of the centrifuge according to a sign is 30 rad/s^2. If starting at rest, what is the rotational velocity of the centrifuge after 10 s?
8. * **Potter's wheel** A fly sits on a potter's wheel 0.30 m from its axle. The wheel's rotational speed decreases from 4.0 rad/s to 2.0 rad/s in 5.0 s. Determine (a) the wheel's average rotational acceleration, (b) the angle through which the fly turns during the 5.0 s, and (c) the distance traveled by the fly during that time interval.
9. * During your tennis serve, your racket and arm move in an approximately rigid arc with the top of the racket 1.5 m from your shoulder joint. The top accelerates from rest to a speed of 20 m/s in a time interval of 0.10 s. Determine (a) the magnitude of the average tangential acceleration of the top of the racket and (b) the magnitude of the rotational acceleration of your arm and racket.
10. * An ant clings to the outside edge of the tire of an exercise bicycle. When you start pedaling, the ant's speed increases from zero to 10 m/s in 2.5 s. The wheel's rotational acceleration is 13 rad/s^2. Determine everything you can about the motion of the wheel and the ant.
11. * The speedometer on a bicycle indicates that you travel 60 m while your speed increases from 0 to 10 m/s. The radius of the wheel is 0.30 m. Determine three physical quantities relevant to this motion.
12. * You pedal your bicycle so that its wheel's rotational speed changes from 5.0 rad/s to 8.0 rad/s in 2.0 s. Determine (a) the wheel's average rotational acceleration, (b) the angle through which it turns during the 2.0 s, and (c) the distance that a point 0.60 m from the axle travels.
13. **Mileage gauge** The odometer on an automobile actually counts axle turns and converts the number of turns to miles based on knowledge that the diameter of the tires is 0.62 m. How many turns does the axle make when traveling 10 miles?
14. * **Speedometer** The speedometer on an automobile measures the rotational speed of the axle and converts that to a linear speed of the car, assuming the car has 0.62-m-diameter tires. What is the rotational speed of the axle when the car is traveling at 20 m/s (45 mph)?
15. * **Ferris wheel** A Ferris wheel starts at rest, acquires a rotational velocity of ω rad/s after completing one revolution and continues to accelerate. Write an expression for (a) the magnitude of the wheel's rotational acceleration (assumed constant), (b) the time interval needed for the first revolution, (c) the time interval required for the second revolution, and (d) the distance a person travels in two revolutions if he is seated a distance l from the axis of rotation.
16. * You push a disk-shaped platform tangentially on its edge 2.0 m from the axle. The platform starts at rest and has a rotational acceleration of 0.30 rad/s^2. Determine the distance you must run while pushing the platform to increase its speed at the edge to 7.0 m/s.
17. ** EST Estimate what Earth's rotational acceleration would be in rad/s^2 if the length of a day increased from 24 h to 48 h during the next 100 years.

9.3 Newton's second law for rotational motion

18. A 0.30-kg ball is attached at the end of a 0.90-m-long stick. The ball and stick rotate in a horizontal circle. Because of air resistance and to keep the ball moving at constant speed, a continual push must be exerted on the stick, causing a 0.036-N · m torque. Determine the magnitude of the resistive force that the air exerts on the ball opposing its motion. What assumptions did you make?
19. **Centrifuge** A centrifuge with a 0.40-kg · m^2 rotational inertia has a rotational acceleration of 100 rad/s^2 when the power is turned on. (a) Determine the minimum torque that the motor supplies. (b) What time interval is needed for the centrifuge's rotational velocity to increase from zero to 5000 rad/s?
20. **Airplane turbine** What is the average torque needed to accelerate the turbine of a jet engine from rest to a rotational velocity of 160 rad/s in 25 s? The turbine's rotating parts have a 32-kg · m^2 rotational inertia.
21. * A turntable turning at rotational speed 33 rpm stops in 50 s when turned off. The turntable's rotational inertia is 1.0×10^{-2} kg · m^2. How large is the resistive torque that slows the turntable?
22. * The solid pulley in Figure P9.22 consists of a two-part disk, which initially rotates counterclockwise. Two ropes pull on the pulley as shown. The inner part has a radius of 1.5a, and the outer part has a radius of 2.0a. (a) Construct a force diagram for the pulley with the origin of the coordinate system at the center of the pulley. (b) Determine the torque produced by each force (including the sign) and the resultant torque exerted on the pulley. (c) Based on the results of part (b), decide on the signs of the rotational velocity and the rotational acceleration.

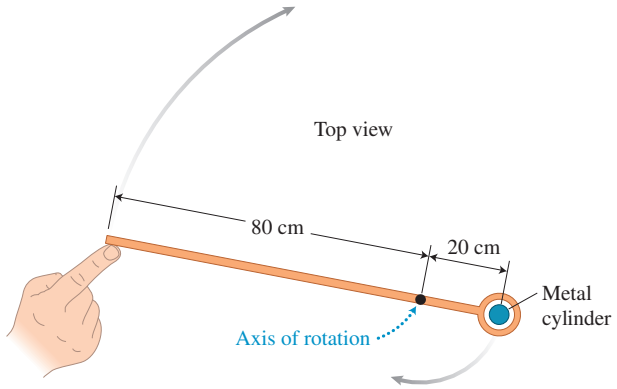


FIGURE P9.22

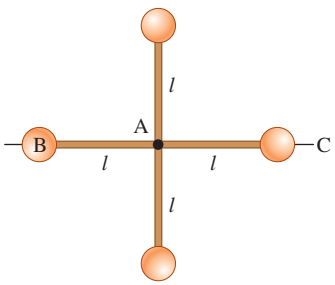
23. * The pulley shown in Figure P9.22 is initially rotating clockwise. Compare the forces exerted by the ropes on the disk in order for the wheel's rotational velocity to (a) remain constant, (b) increase in magnitude, and (c) decrease in magnitude. The outer radius is 2.0a compared to 1.5a for the inner radius.
24. The pulley shown in Figure P9.22 is initially rotating in the clockwise direction. The force that the rope on the right exerts on it is 1.5F and the force that the rope on the left exerts on it is F. Determine the ratio of the maximum radius of the inner circle compared to that of the outer circle in order for the wheel's rotational speed to decrease.

25. A 2.0-kg metal cylinder on a table is placed inside a hoop that is fixed at the end of a meter stick. The stick can rotate around a vertical axis that is located 20 cm from the cylinder (see **Figure P9.25**). By exerting a force on the stick, you can make the cylinder rotate in a horizontal plane, with the bottom surface of the cylinder sliding on the rough table. The coefficient of kinetic friction between the cylinder and the table is 0.3. (a) Determine the magnitude of the force that you need to exert on the end of the stick (perpendicular to it) so that the cylinder moves with a constant speed. (b) Determine the work done by your hand on the stick while your hand makes one full turn around the axis. Then determine the work done by the stick on the cylinder during the same time. Compare the two values and comment on the result. Does the result surprise you?

FIGURE P9.25

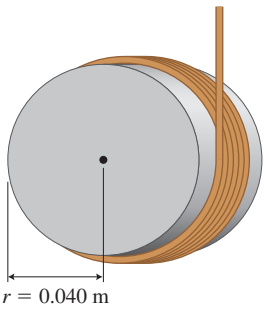
26. * **Equation Jeopardy 1** The equation below describes a rotational dynamics situation. Draw a sketch of a situation that is consistent with the equation and construct a word problem for which the equation might be a solution. There are many possibilities.



$$-(2.2\text{ N})(0.12\text{ m}) = [(1.0\text{ kg})(0.12\text{ m})^2]\alpha$$

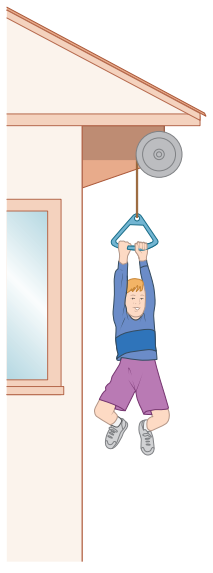
27. * **Equation Jeopardy 2** The equation below describes a rotational dynamics situation. Draw a sketch of a situation that is consistent with the equation and construct a word problem for which the equation might be a solution. There are many possibilities.

$$-(2.0\text{ N})(0.12\text{ m}) + (6.0\text{ N})(0.06\text{ m}) = [(1.0\text{ kg})(0.12\text{ m})^2]\alpha$$



28. Derive an expression for the rotational inertia of the four balls shown in **Figure P9.28** about an axis perpendicular to the paper and passing through point A. The mass of each ball is m. Ignore the mass of the rods to which the balls are attached.

FIGURE P9.28



29. * Repeat the previous problem for an axis perpendicular to the paper through point B.
30. Repeat the previous problem for axis BC, which passes through two of the balls.
31. * **Merry-go-round** A mechanic needs to replace the motor for a merry-go-round. What torque specifications must the new motor satisfy if the merry-go-round should accelerate from rest to 1.5 rad/s in 8.0 s? You can consider the merry-go-round to be a uniform disk of radius 5.0 m and mass 25,000 kg.
32. * A small 0.80-kg train propelled by a fan engine starts at rest and goes around a circular track with a 0.80-m radius. The air exerts a 2.0-N force on the train. Determine (a) the rotational acceleration of the train and (b) the time interval needed for it to acquire a speed of 3.0 m/s. Indicate any assumptions you made.
33. * **Motor** You wish to buy a motor that will be used to lift a 20-kg bundle of shingles from the ground to the roof of a house. The shingles are to have a 1.5-m/s^2 upward acceleration at the start of the lift. The very light pulley on the motor has a radius of 0.12 m. Determine the minimum torque that the motor must be able to provide.
34. ** A string wraps around a 6.0-kg wheel of radius 0.20 m. The wheel is mounted on a frictionless horizontal axle at the top of an inclined plane tilted 37° below the horizontal. The free end of the string is attached to a 2.0-kg block that slides down the incline without friction. The block's acceleration while sliding down the incline is 2.0 m/s^2. (a) Draw separate force diagrams for the wheel and for the block. (b) Apply Newton's second law (either the translational form or the rotational form) for the wheel and for the block. (c) Determine the rotational inertia for the wheel about its axis of rotation.
35. * Elena, a black belt in tae kwon do, is experienced in breaking boards with her fist. A high-speed video indicates that her forearm is moving with a rotational speed of 40 rad/s when it reaches the board. The board breaks in 0.0040 s and her arm is moving at 20 rad/s just after breaking the board. Her fist is 0.32 m from her elbow joint and the rotational inertia of her forearm is 0.050 kg · m^2. Determine the average force that the board exerts on her fist while breaking the board (equal in magnitude to the force that her fist exerts on the board). Ignore the gravitational force that Earth exerts on her arm and the force that her triceps muscle exerts on her arm during the break.
36. ** **Like a yo-yo** Sam wraps a string around the outside of a 0.040-m-radius 0.20-kg solid cylinder and uses it like a yo-yo (**Figure P9.36**). When released, the cylinder accelerates downward at $(2/3)g$. (a) Draw a force diagram for the cylinder and apply the translational form of Newton's second law to the cylinder in order to determine the force that the string exerts on the cylinder. (b) Determine the rotational inertia of the solid cylinder. (c) Apply the rotational form of Newton's second law and determine the cylinder's rotational acceleration. (d) Is your answer to part (c) consistent with the application of $a = r\alpha$, which relates the cylinder's linear acceleration and its rotational acceleration? Explain.

FIGURE P9.36

37. * **Fire escape** A unique fire escape for a three-story house is shown in **Figure P9.37**. A 30-kg child grabs a rope wrapped around a heavy flywheel outside a bedroom window. The flywheel is a 0.40-m-radius uniform disk with a mass of 120 kg. (a) Make a force diagram for the child as he moves downward at increasing speed and another for the flywheel as it turns faster and faster. (b) Use Newton's second law for translational motion and the child force diagram to obtain an expression relating the force that the rope exerts on him and his acceleration. (c) Use Newton's second law for rotational motion and the flywheel force diagram to obtain an expression relating the force the rope exerts on the flywheel and the rotational acceleration of the flywheel. (d) The child's acceleration a and the flywheel's rotational acceleration α are related by the equation $a = r\alpha$, where r is the flywheel's radius. Combine this with your equations in parts (b) and (c) to determine the child's acceleration and the force that the rope exerts on the wheel and on the child.

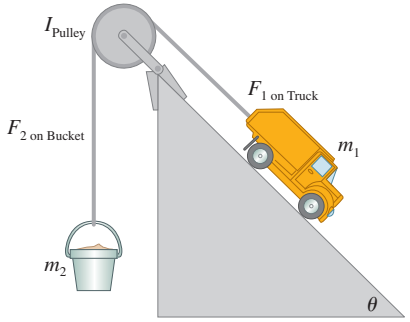


FIGURE P9.37

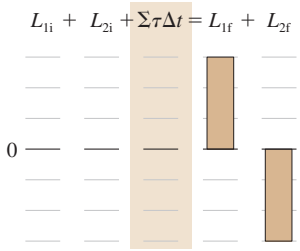
38. ** An Atwood machine is shown in Example 9.4. Use $m_1 = 0.20$ kg, $m_2 = 0.16$ kg, $M = 0.50$ kg, and $R = 0.10$ m. (a) Construct separate force diagrams for block 1, for block 2, and for the solid cylindrical pulley. (b) Determine the rotational inertia of the pulley. (c) Use the force diagrams for blocks 1 and 2 and Newton's second law to write expressions relating the unknown accelerations of the blocks. (d) Use the pulley force diagram and the rotational form of Newton's second law to write an expression for the rotational acceleration of the pulley. (e) Noting that $a = R\alpha$ for the pulley, use the three equations from parts (c) and (d) to determine the magnitude of the acceleration of the hanging blocks.

39. ** A physics problem involves a massive pulley, a bucket filled with sand, a toy truck, and an incline (see **Figure P9.39**). You push lightly on the truck so it moves down the incline. When you stop pushing, it moves down the incline at constant speed and the bucket moves up at constant speed. (a) Construct separate force diagrams for the pulley, the bucket, and the truck. (b) Use the truck force diagram and the bucket force diagram to help write expressions in terms of quantities shown in the figure for the forces $F_{1\text{ on Truck}}$ and $F_{2\text{ on Bucket}}$ that the rope exerts on the truck and that the rope exerts on the bucket. (c) Use the rotational form of Newton's second law to determine if the tension force $F_{1\text{ on Pulley}}$ that the rope on the right side exerts on the pulley is the same, greater than, or less than the force $F_{2\text{ on Pulley}}$ that the rope exerts on the left side.

FIGURE P9.39

40. * A thin rod of length L and mass m rotates around an axis perpendicular to the rod, passing through the rod's left end. Treat the rod as an object made up of five rods of length $L/5$. Derive an expression for the rotational inertia of this five-piece object around the same axis, assuming each piece is a point-like object with mass $m/5$. Compare your result with the expression for the rotational inertia of the one-piece rod ($I = \frac{1}{3}mL^2$). Discuss the similarities and the differences.



9.4 Rotational momentum

41. * (a) Determine the rotational momentum of a 10-kg disk-shaped flywheel of radius 9.0 cm rotating with a rotational speed of 320 rad/s. (b) With what magnitude rotational speed must a 10-kg solid sphere of 9.0 cm radius rotate to have the same rotational momentum as the flywheel?
42. **Ballet** A ballet student with her arms and a leg extended spins with an initial rotational speed of 1.0 rev/s. As she draws her arms and leg in toward her body, her rotational inertia becomes 0.80 kg · m^2 and her rotational velocity is 4.0 rev/s. Determine her initial rotational inertia.
43. * A 0.20-kg block moves at the end of a 0.50-m string along a circular path on a frictionless air table. The block's initial rotational speed is 2.0 rad/s. As the block moves in the circle, the string is pulled down through a hole in the air table at the axis of rotation. Determine the rotational speed and tangential speed of the block when the string is 0.20 m from the axis.
44. * **Puck on a string** You attach a 100-g puck to a string and let the puck glide in a circle on a horizontal, frictionless air table. The other end of the string passes through a hole at the center of the table. You pull down on the string so that the puck moves along a circular path of radius 0.40 m. It completes one revolution in 4.0 s. If you pull harder on the string so the radius of the circle slowly decreases to 0.20 m, what is the new period of revolution?
45. * **Equation Jeopardy 3** The equation below describes a process. Draw a sketch representing the initial and final states of the process and construct a word problem for which the equation could be a solution.

$$\left(\frac{2}{5}mR^2\right)\left(\frac{2\pi}{30\text{ days}}\right) = \left[\frac{2}{5}m\left(\frac{R}{100}\right)^2\right]\left(\frac{2\pi}{T_f}\right)$$

46. ** A student sits motionless on a stool that can turn friction-free about its vertical axis (total rotational inertia I). The student is handed a spinning bicycle wheel, with rotational inertia I_{wheel}, that is spinning about a vertical axis with a counterclockwise rotational velocity ω_0. The student then turns the bicycle wheel over (that is, through 180°). Estimate, in terms of ω_0, the final rotational velocity acquired by the student.
47. * **Neutron star** An extremely dense neutron star with mass equal to that of the Sun has a radius of about 10 km—about the size of Manhattan Island. These stars are thought to rotate once about their axis every 0.03 to 4 s, depending on their size and mass. Suppose that the neutron star described in the first sentence rotates once every 0.040 s. If its volume then expanded to occupy a uniform sphere of radius 1.4×10^8 m (most of the Sun's mass is in a sphere of this size) with no change in mass or rotational momentum, what time interval would be required for one rotation? By comparison, the Sun rotates once about its axis each month.
48. * A boy of mass m is standing on the edge of a merry-go-round platform, which is initially rotating with a constant rotational velocity ω_i (initial state). The rotational inertia of the merry-go-round is I, and the radius of the platform is r. After the boy steps down from the platform, tangentially to its edge, the merry-go-round continues rotating with a smaller rotational velocity ω_f, and the boy continues moving away from the platform with constant speed v (final state). (a) Draw three rotational momentum bar charts, choosing the boy, the merry-go-round, and both of them as a system. (b) Derive the expression for ω_f in terms of the relevant quantities.
49. * **Bar chart jeopardy** The rotational momentum bar chart in **Figure P9.49** describes a rotational dynamics situation. Draw a sketch of a situation that is consistent with the equation and write a word problem to which the bar chart could apply.

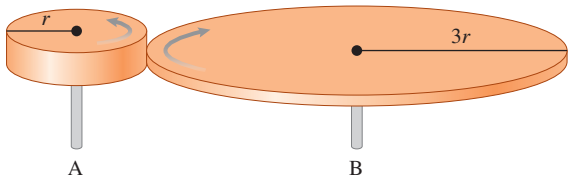


FIGURE P9.49

9.5 Rotational kinetic energy

50. A grinding wheel with rotational inertia I gains rotational kinetic energy K after starting from rest. Determine an expression for the wheel's final rotational speed.
51. * The rotational speed of a flywheel increases by 40%. By what percent does its rotational kinetic energy increase? Explain your answer.
52. ** Two uniform disks are made from the same material and have equal masses. The radius of disk B is three times larger than the radius of disk A. The disks touch each other and rotate at constant angular speed without skidding (**Figure P9.52**). Determine (a) the ratio of the disks' thicknesses d_B/d_A, (b) the ratio of the disks' angular velocities ω_B/ω_A, (c) the ratio of the disks' rotational inertias I_B/I_A, (d) the ratio of the disks' rotational momenta L_B/L_A, and (e) the ratio of the disks' rotational kinetic energies $K_{\text{rot B}}/K_{\text{rot A}}$.

FIGURE P9.52

53. * **Flywheel energy for car** The U.S. Department of Energy had plans for a 1500-kg automobile to be powered completely by the rotational kinetic energy of a flywheel. (a) If the 300-kg flywheel (included in the 1500-kg mass of the automobile) had a 6.0-kg · m^2 rotational inertia and could turn at a maximum rotational speed of 3600 rad/s, determine the energy stored in the flywheel. (b) How many accelerations from a speed of zero to 15 m/s could the car make before the flywheel's energy was dissipated, assuming 100% energy transfer and no flywheel regeneration during braking? Ignore rotational kinetic energy of car wheels.

54. * **Flywheel energy** Engineers at the University of Texas at Austin are developing an Advanced Locomotive Propulsion System that uses a gas turbine and perhaps the largest high-speed flywheel in the world in terms of the energy it can store. The flywheel can store 4.8×10^8 J of energy when operating at its maximum rotational speed of 15,000 rpm. At that rate, the perimeter of the rotor moves at approximately 1,000 m/s. Determine the radius of the flywheel and its rotational inertia.

55. * **Equation Jeopardy 4** The equations below represent the initial and final states of a process (plus some ancillary information). Construct a sketch of a process that is consistent with the equations and write a word problem for which the equations could be a solution.

$$(80\text{ kg})(9.8\text{ N/kg})(16\text{ m}) = \tfrac{1}{2}(80\text{ kg})v_f^2 + \tfrac{1}{2}(240\text{ kg}\cdot\text{m}^2)\omega_f^2$$
$$v_f = (0.40\text{ m})\omega_f$$

56. ** **Rotating student** A student sitting on a chair on a circular platform of negligible mass rotates freely on an air table at initial rotational speed 2.0 rad/s. The student's arms are initially extended with 6.0-kg dumbbells in each hand. As the student pulls her arms in toward her body, the dumbbells move from a distance of 0.80 m to 0.10 m from the axis of rotation. The initial rotational inertia of the student's body (not including the dumbbells) with arms extended is 6.0 kg · m^2, and her final rotational inertia is 5.0 kg · m^2. (a) Determine the student's final rotational speed. (b) Determine the change of kinetic energy of the system consisting of the student together with the two dumbbells. (c) Determine the change in the kinetic energy of the system consisting of the two dumbbells alone without the student. (d) Determine the change of kinetic energy of the system consisting of the student alone without the dumbbells. (e) Compare the kinetic energy changes in parts (b) through (d).

57. * A turntable whose rotational inertia is 1.0×10^{-3} kg · m^2 rotates on a frictionless air cushion at a rotational speed of 2.0 rev/s. A 1.0-g beetle falls to the center of the turntable and then walks 0.15 m to its edge. (a) Determine the rotational speed of the turntable with the beetle at the edge. (b) Determine the kinetic energy change of the system consisting of the turntable and the beetle. (c) Account for this energy change.

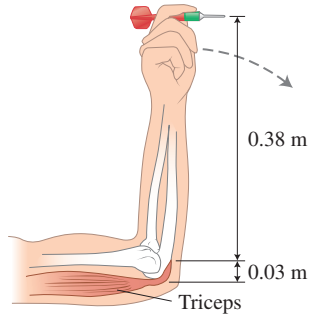
58. ** Repeat the previous problem, only assume that the beetle initially falls on the edge of the turntable and stays there.

59. * A bug of a known mass m stands at a distance d cm from the axis of a spinning disk (mass m_d and radius r_d) that is rotating at f_i revolutions per second. After the bug walks out to the edge of the disk and stands there, the disk rotates at f_f revolutions per second. (a) Use the information above to write an expression for the rotational inertia of the disk. (b) Determine the change of kinetic energy in going from the initial to the final situation for the total bug-disk system.

60. * **Merry-go-round** A carnival merry-go-round has a large disk-shaped platform of mass 120 kg that can rotate about a center axle. A 60-kg student stands at rest at the edge of the platform 4.0 m from its center. The platform is also at rest. The student starts running clockwise around the edge of the platform and attains a speed of 2.0 m/s relative to the ground. (a) Determine the rotational velocity of the platform. (b) Determine the change of kinetic energy of the system consisting of the platform and the student.

61. * EST You hold an apple by its stem between your thumb and index finger and spin it so that the apple is rotating at approximately constant speed. Estimate the rotational kinetic energy and the rotational momentum of the apple. Indicate any assumptions that you made.

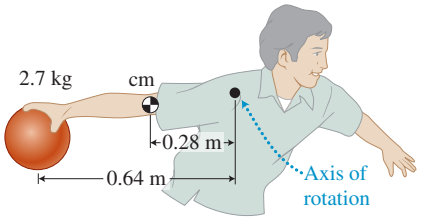
General Problems



62. * **Stopping Earth's rotation** Suppose that Superman wants to stop Earth so it does not rotate. He exerts a force on Earth $\vec{F}_{S\text{ on }E}$ at Earth's equator tangent to its surface for a time interval of 1 year. What magnitude force must he exert to stop Earth's rotation? Indicate any assumptions you make when completing your estimate.

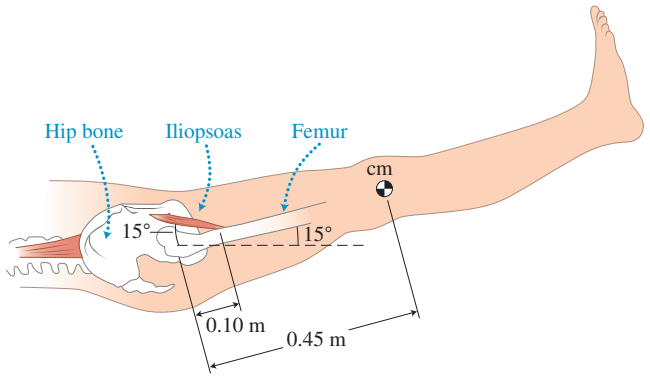
63. * BIO EST **Punting a football** Estimate the tangential acceleration of the foot and the rotational acceleration of the leg of a football punter during the time interval that the leg starts to swing forward in an arc until the instant just before the foot hits the ball. Indicate any assumptions that you make and be sure that your method is clear.

64. * EST Estimate the average rotational acceleration of a car tire as you leave an intersection after a light turns green. Discuss the choice of numbers used in your estimate.



65. * BIO **Triceps and darts** Your upper arm is horizontal and your forearm is vertical with a 0.010-kg dart in your hand (Figure P9.65). When your triceps muscle contracts, your forearm initially swings forward with a rotational acceleration of 35 rad/s^2. Determine the force that your triceps muscle exerts on your forearm during this initial part of the throw. The rotational inertia of your forearm is 0.12 kg · m^2 and the dart is 0.38 m from your elbow joint. Your triceps muscle attaches 0.03 m from your elbow joint.

FIGURE P9.65



66. * BIO **Bowling** At the start of your throw of a 2.7-kg bowling ball, your arm is straight behind you and horizontal (Figure P9.66). Determine the rotational acceleration of your arm if the muscle is relaxed. Your arm is 0.64 m long, has a rotational inertia of 0.48 kg · m^2, and has a mass of 3.5 kg with its center of mass 0.28 m from your shoulder joint.

FIGURE P9.66

67. ** BIO **Leg lift** You are doing one-leg leg lifts (Figure P9.67) and decide to estimate the force that your iliopsoas muscle exerts on your upper leg bone (the femur) when being lifted (the lifting involves a variety of muscles). The mass of your entire leg is 15 kg, its center of mass is 0.45 m from the hip joint, and its rotational inertia is 4.0 kg · m^2, and you estimate that the rotational acceleration of the leg being lifted is 35 rad/s^2. For calculation purposes assume that the iliopsoas attaches to the femur 0.10 m from the hip joint. Also assume that the femur is oriented 15° above the horizontal and that the muscle is horizontal. Estimate the force that the muscle exerts on the femur.

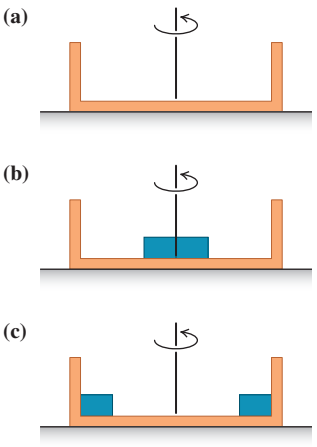


FIGURE P9.67

68. * A horizontal, circular platform can rotate around a vertical axis at its center with negligible friction. You decide to use the rotating platform to design a procedure that will allow you to determine the unknown rotational inertias of different objects, for example, a bowl. You know the rotational inertia of the platform I_P. Which of the following procedures would best serve your task? (More than one answer could be correct.) Comment on the procedures that are not suitable and explain what is wrong with them.
   (a) Exert a constant torque τ on the empty platform and measure its angular acceleration α_P. Then place the bowl on the platform at its center and repeat the previous experiment, obtaining α_{PB}. Calculate the rotational inertia of the bowl using the expression $I_B = \dfrac{\tau}{\alpha_{PB} - \alpha_P}$.
   (b) Perform the same experiment as in (a) but use the expression $I_B = I_P\left(\dfrac{\alpha_P}{\alpha_{PB}} - 1\right)$.
   (c) Spin the empty platform and measure its angular velocity ω_i. While the platform is rotating, place the bowl carefully on the platform at its center. Wait until the bowl rotates together with the platform. Measure the final angular velocity of the bowl-platform system ω_f. Calculate the rotational inertia of the bowl using the expression $I_B = I_P\left(\dfrac{\omega_i}{\omega_f} - 1\right)$.
   (d) Perform the same experiment as in (c) but use the expression $I_B = I_P\left(\dfrac{\omega_i^2}{\omega_f^2} - 1\right)$.
   (e) Measure the mass of the platform m_P, the mass of the bowl m_B, the radius of the platform r_P, and the radius of the bowl r_B. Calculate the rotational inertia of the bowl using the expression $I_B = I_P \cdot \dfrac{m_B r_B^2}{m_P r_P^2}$.

69. * You have an empty cylindrical metal can and two metal nuts. In your first experiment, you spin the can around its axis and place it on a rough table (**Figure P9.69a**). The can slows down due to friction, with the rotational acceleration $\alpha_1 = 30\ \text{rad/s}^2$ until it stops rotating. In your second experiment, you first fix two nuts near the center of the can (Figure P9.69b) and spin it again before placing it on the table. In this case, the can slows down with the rotational acceleration $\alpha_2 = 38\ \text{rad/s}^2$. In your third experiment, you spin the can with the nuts fixed at opposite sides of the can (Figure P9.69c). Now the can slows down with rotational acceleration $\alpha_3 = 26\ \text{rad/s}^2$. Explain (a) why $\alpha_2 > \alpha_1$, (b) why $\alpha_3 < \alpha_2$, and (c) why $\alpha_3 < \alpha_1$.

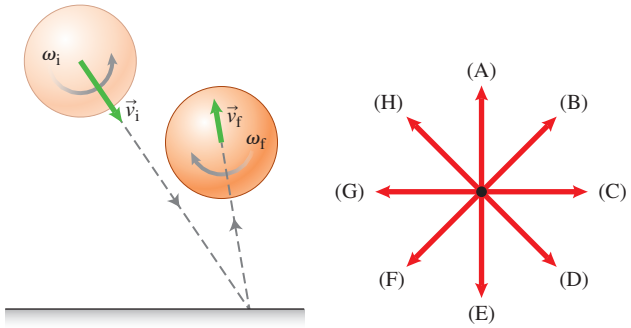

FIGURE P9.69

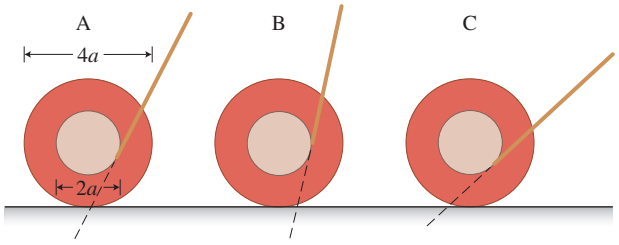
70. ** In the previous problem, each nut has a mass of 8.0 g. The distances between the centers of mass of the nuts and the axis of rotation are 0.8 cm in Experiment 2 and 3.5 cm in Experiment 3. Determine the rotational inertia of the can (without nuts). Indicate any assumptions that you made. (Hint: The torque due to the kinetic friction force in Experiments 2 and 3 is the same.)

71. * **Superball** If you give a superball backspin and throw it toward a horizontal floor, it is possible that the ball bounces backward, as shown in **Figure P9.71**. If the ball has a color pattern or stripes, you may also notice that during the collision with the ground, the direction of rotation of the ball changes, as indicated in the figure. Both changes (the change of the ball's translational velocity and the change of the ball's angular velocity) are the result of a force exerted on the ball by the ground during the collision. (a) In which approximate direction did the ground exert the force on the ball in the case shown in the figure? Choose the best answer from the options given in the figure and explain your answer. (b) The ball has initial and final velocity (with components v_{xi}, v_{yi} and v_{xf}, v_{yf}) and initial and final angular velocity (ω_i and ω_f). During the collision, the ground exerts a force

FIGURE P9.71

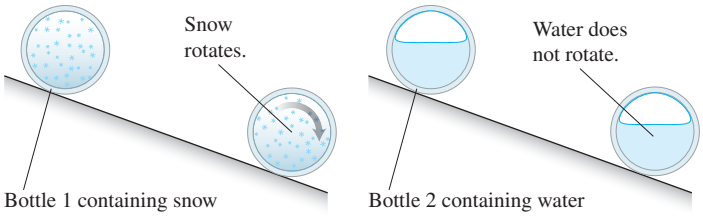


(determined by F_x and F_y) on the ball. Complete the table below by drawing crosses in the cells that correctly connect changes of the quantities in the first column and the components of the force during the collision. Explain your answers.

	F_x	F_y
$v_{xf} - v_{xi}$		
$v_{yf} - v_{yi}$		
$\omega_f - \omega_i$		

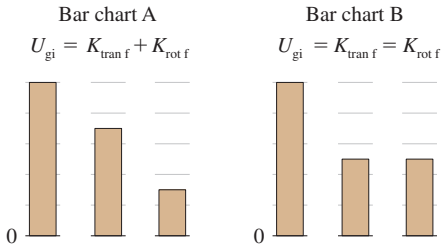
72. ** **Yo-yo trick** A yo-yo rests on a horizontal table. The yo-yo is free to roll but friction prevents it from sliding. When the string exerts one of the following tension forces on the yo-yo (shown in **Figure P9.72**), which way does the yo-yo roll? Try the problem for each force: (a) $\vec{T}_{A\ S\ on\ Y}$; (b) $\vec{T}_{B\ S\ on\ Y}$; and (c) $\vec{T}_{C\ S\ on\ Y}$. (Hint: Think about torques about a pivot point where the yo-yo touches the table.)

FIGURE P9.72



73. * EST **White dwarf** A star the size of our Sun runs out of nuclear fuel and, without losing mass, collapses to a white dwarf star the size of our Earth. If the star initially rotates at the same rate as our Sun, which is once every 25 days, determine the rotation rate of the white dwarf. Indicate any assumptions you make.

Reading Passage Problems

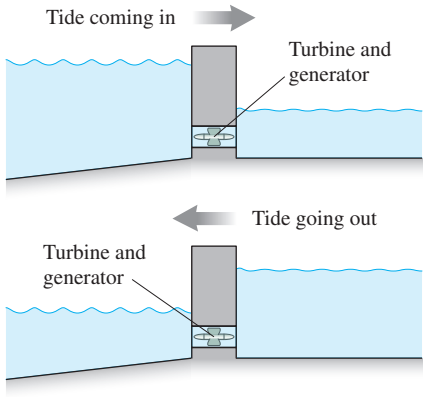


Rolling versus sliding Our knowledge of rotational kinetic energy helps explain a very simple but rather mysterious experiment that you can perform at home. For this experiment, you need two identical plastic water bottles (1 and 2). Fill bottle 1 with snow (if you do not have snow, you can use whipped cream). Fill bottle 2 with water so that the masses of filled bottles are the same. Place one bottle at the top of an inclined plane and let it roll down. Then repeat the experiment with the other bottle (**Figure 9.18**). You observe an interesting effect: when bottle 1 rolls down, it rotates and the solid snow inside rotates with the bottle. Bottle 2 rotates, too, but the water inside does not rotate much. Thus, in effect, the water slides down the incline and does not roll. When the snow-filled bottle rolls down, it rotates as a solid cylinder, acquiring rotational kinetic energy in addition to translational kinetic energy. In the case of the water-filled bottle, only the bottle rotates; the water inside just translates. Rolling is a combination of translation and rotation, whereas sliding involves only translation. The water bottle has almost no rotational kinetic energy and a larger translational kinetic energy at the end of the plane.

FIGURE 9.18

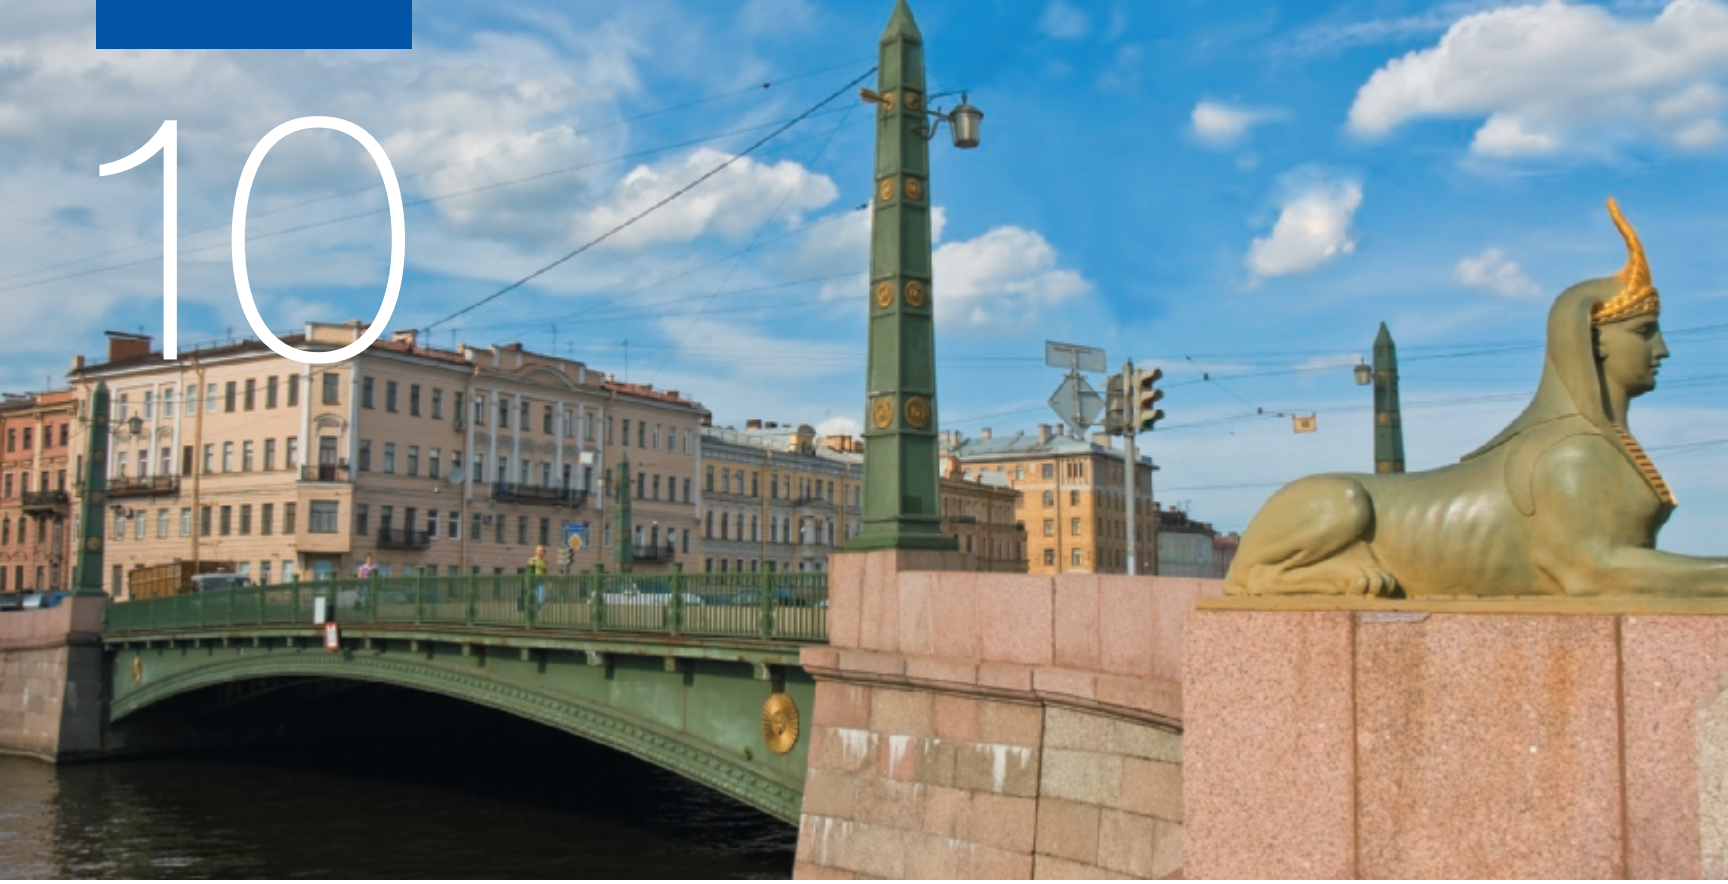
74. Which bar chart in **Figure P9.74** corresponds to the bottle filled with solid snow rolling from the top of the incline to the bottom?
    (a) Bar chart A
    (b) Bar chart B
    (c) Both charts could represent the trip.

FIGURE P9.74



75. Which bar chart in **Figure P9.74** corresponds to the bottle with the shortest time interval from the top of the incline to the bottom?
    (a) Bar chart A
    (b) Bar chart B
    (c) The charts represent the same time interval for the trip.
76. Based on the results from the two previous questions, which bottle should take the shortest time interval to complete the race?
    (a) Bottle 1
    (b) Bottle 2
    (c) Both bottles take the same time interval.
77. Which statement best explains your answer to the previous problem?
    (a) Most of the initial gravitational potential energy is converted into translational kinetic energy.
    (b) Some of the initial gravitational potential energy is converted to rotational kinetic energy.
    (c) All initial gravitational potential energy is converted to kinetic energy.

Tidal energy Tides are now used to generate electric power in two ways. In the first, huge dams can be built across the mouth of a river where it exits to the ocean. As the ocean tide moves in and out of this tidal basin or estuary, the water flows through tunnels in the dam (see **Figure 9.19**). This flowing water turns turbines in the tunnels that run electric generators. Unfortunately, this technique works best with large increases in tides—a 5-m difference between high and low tide. Such differences are found at only a small number of places. Currently, France is the only country that successfully uses this power source. A tidal basin plant in France, the Rance Tidal Power Station, makes 240 megawatts of power—enough energy to power 240,000 homes. Damming tidal basins can have negative environmental effects because of reduced tidal flow and silt buildup. Another disadvantage is that they can only generate electricity when the tide is flowing in or out, for about 10 hours each day.



A second method for collecting energy from the tidal flow (as well as all water flow) is to place turbines directly in the water—like windmills in moving water instead of in moving air. These water turbines have the advantages that they are much cheaper to build, they do not have the environmental problems of a tidal basin, and there are many more suitable sites for such water flow energy farms. Also, the energy density of flowing water is about 800 times the energy density of dry air flow. Verdant Power is developing turbine prototypes in the East River near New York City and in the Saint Lawrence Seaway in Canada, and they are looking at other sites in the Puget Sound and all over the world. The worldwide potential for hydroelectric power is about 25 terawatts $= 25 \times 10^{12}$ J/s—enough to supply the world's energy needs.

FIGURE 9.19 Dams built across tidal basins can generate electric power.

As the tide rises and falls, water passes through the turbine, which runs a generator.

78. If the Rance Tidal Power Station in France could produce power 24 hours a day, which answer below is closest to the daily amount of energy in joules that it could produce?
    (a) 240 J
    (b) 240×10^6 J
    (c) 6×10^9 J
    (d) 2.5×10^{10} J
    (e) 2×10^{13} J
79. Suppose a tidal basin is 5 m above the ocean at low tide and that the area of the basin is 4×10^7 m^2 (about 4 miles by 4 miles). Which answer below is closest to the gravitational potential energy change if the water is released from the tidal basin to the low-tide ocean level? The density of water is 1000 kg/m^3. (Hint: The level does not change by 5 m for all of the water.)
    (a) 5×10^8 J
    (b) 5×10^{11} J
    (c) 1×10^{12} J
    (d) 5×10^{12} J
    (e) 1×10^{13} J
80. The Rance tidal basin can only produce electricity when what is occurring?
    (a) Water is moving into the estuary from the ocean.
    (b) Water is moving into the ocean from the estuary.
    (c) Water is moving in either direction.
    (d) The Moon is full.
    (e) The Moon is full and directly overhead.
81. Why do water turbines seem more promising than tidal basins for producing electric energy?
    (a) Turbines are less expensive to build.
    (b) Turbines have less impact on the environment.
    (c) There are many more locations for turbines than for tidal basins.
    (d) Turbines can operate 24 hours/day versus only 10 hours/day for tidal basins.
    (e) All of the above
82. Why do water turbines have an advantage over air turbines (windmills)?
    (a) Air moves faster than water.
    (b) The energy density of moving water is much greater than that of moving air.
    (c) Water turbines can float from one place to another, whereas air turbines are fixed.
    (d) All of the above
    (e) None of the above
83. Which of the following is a correct statement about water turbines?
    (a) Water turbines can operate only in moving tidal water.
    (b) Water turbines can produce only a small amount of electricity.
    (c) Water turbines have not had a proof of concept.
    (d) Water turbines cause significant ocean warming.
    (e) None of the above are correct statements.

10

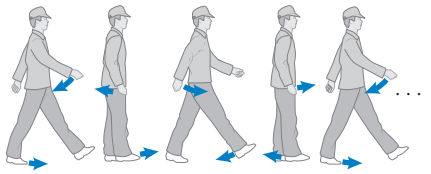
Vibrational Motion

- **Why should soldiers avoid marching in step when they cross a bridge?**
- **Why do you need to "pump" your legs when you begin swinging on a park swing?**
- **How can you carry a full cup of coffee without splashing it?**

On a cold day in January 1905, a Russian cavalry squadron of 50 soldiers was crossing a bridge over the Fontanka River in St. Petersburg when it collapsed. The stone bridge had stood for 79 years, with many more people simultaneously walking or riding horses across it than there were soldiers in that squadron. However, unlike ordinary crowds, the Russian soldiers were marching in step as they crossed the bridge. Why did their marching cause the bridge to collapse? We will find out in this chapter.

BE SURE YOU KNOW HOW TO:

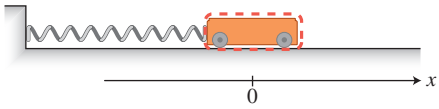
- Apply Hooke's law to analyze forces exerted by springs (Section 7.4).
- Use radians to describe angles (Section 9.1).
- Draw an energy bar chart for a process and convert it into an equation (Sections 7.2 and 7.6).

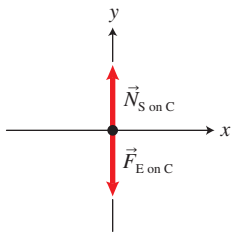


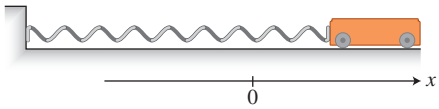
WE HAVE STUDIED LINEAR MOTION—objects moving in straight lines at either constant velocity or constant acceleration. We have also studied objects moving at constant speed in a circle. In the case of circular motion, the direction of the velocity and acceleration of the objects changes, although the magnitude of both usually remains constant. In this chapter we will encounter a new type of motion during which both direction and speed change. You experience this motion every day—when you walk, when you talk, and when you listen to music.

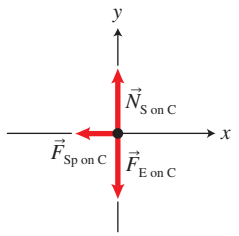
10.1 Observations of vibrational motion

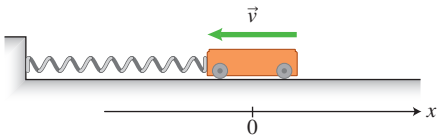
When you walk, your arms and legs swing back and forth. These motions repeat themselves; your arm or your leg passes all of the same points multiple times along its path relative to your body (**Figure 10.1**). The back-and-forth motion of an object that passes through the same positions, first moving in one direction and then in the opposite direction, is an important feature of *vibrational motion*, which we will investigate in this chapter.

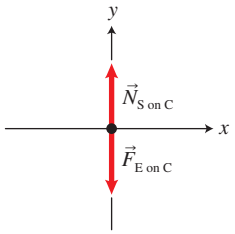


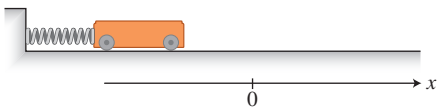


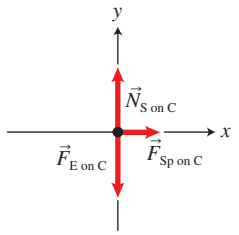












Let's start with some observational experiments using a cart on a smooth surface attached to a spring (Observational Experiment **Table 10.1**). Recall that a spring exerts a force on an object that stretches or compresses the spring (Chapter 7). The force is variable in magnitude and points in the direction opposite to the direction in which the spring is stretched or compressed.

FIGURE 10.1 Vibrational motion. Your arms and legs undergo repetitive back-and-forth motion relative to the body while you walk.

OBSERVATIONAL EXPERIMENT TABLE 10.1 Some features of vibrational motion

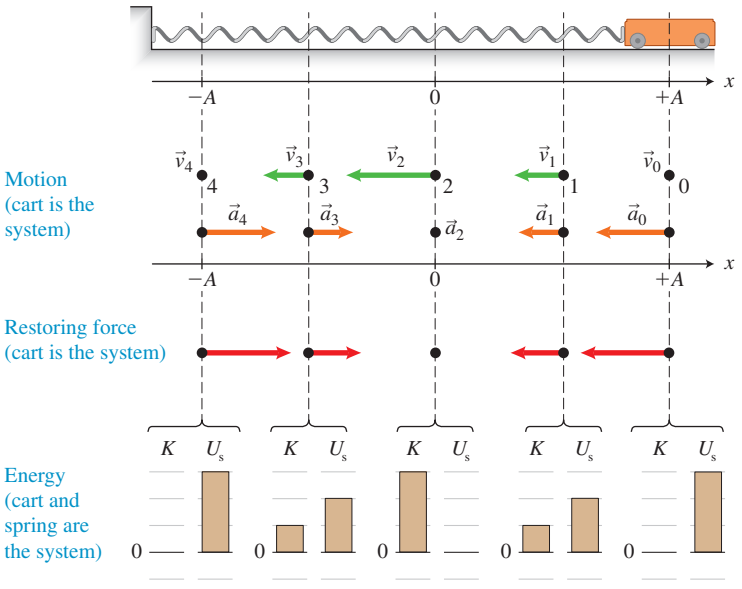
VIDEO OET 10.1

Observational experiment	Analysis
Experiment 1. A cart attached to a relaxed spring sits at rest on a frictionless horizontal surface at position 0. 	In all experiments, we choose the cart as the system. The spring is relaxed, and the sum of the forces exerted on the cart by other objects is zero when at position 0. 
Experiment 2. (a) Pull the cart to the right and release it. The cart starts to move back toward position 0. 	The spring exerts a force on the cart toward the left. The sum of the forces exerted on the cart now points to the left and causes the cart to start moving left toward position 0. 
(b) The cart is moving fast when it reaches position 0 and overshoots that position. 	As the cart passes position 0, the sum of the forces that other objects exert on the cart is again zero. But since it is moving, it continues moving. 
(c) The cart now slows down and eventually stops to the left of position 0, then starts moving back to the right toward position 0. 	After passing position 0, the spring exerts a force to the right toward position 0; the sum of the forces points to the right, causing the cart to slow down, stop, and move back toward position 0. 
(d) The cart overshoots again and eventually stops where it started, on the right side of 0. The motion then repeats itself.	

Patterns

The system is at rest in a particular position when not vibrating. When the cart is at rest in this position, the sum of the forces that other objects exert on it is zero. When the cart is displaced from this position and released, the cart moves back and forth, passing through that position in two opposite directions. If displaced from the rest position, a force is exerted on the vibrating object that tends to return it to that position.

In Table 10.1, the cart attached to the spring vibrates back and forth through what is called its **equilibrium position**—the place where it resides when not disturbed. When the cart is displaced on either side of the equilibrium position, the spring exerts a so-called **restoring force** on the cart that tends to return it to that equilibrium position. However, the cart is moving when it reaches the equilibrium position and therefore overshoots, moving to the other side before turning back toward the equilibrium position.



Equilibrium position (or just **equilibrium**) The position at which a vibrating object resides when not disturbed. When resting at this position, the sum of the forces that other objects exert on it is zero. During **vibrational motion** the object passes back and forth through this position from two opposite directions.

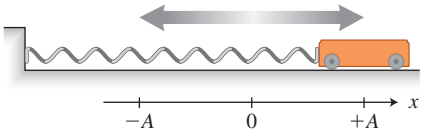
Restoring force When an object is displaced from equilibrium, some other object exerts a force with a component that always points opposite the direction of the vibrating object's displacement from equilibrium. This force tends to restore the vibrating object back toward equilibrium.

We have analyzed the vibrational motion of the cart-spring system using sketches and force diagrams. In Observational Experiment **Table 10.2**, we also use motion diagrams and energy bar charts to see if there are other common characteristics of vibrating systems.

OBSERVATIONAL EXPERIMENT TABLE 10.2  **Multiple representation analysis of a cart on a spring**

VIDEO OET 10.2

Observational experiment	Analysis
A cart attached to a spring is pulled to the right (position $+A$) and released. It moves past equilibrium (position 0) at high speed and briefly stops an equal distance to the left of equilibrium (position $-A$). The spring pushes the cart back toward the right. The process repeats over and over. We analyze the process using motion diagrams, force diagrams, and energy bar charts for one half of the period of vibration.	



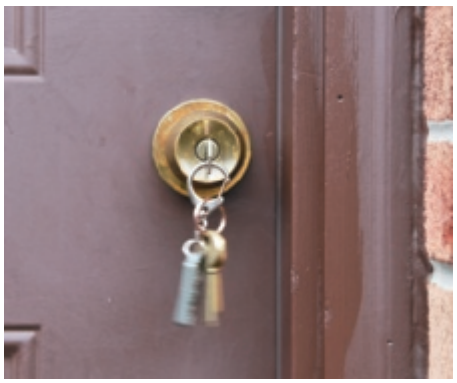
Pattern

Restoring force The restoring force is zero as the vibrating object passes through the equilibrium position and has maximum magnitude when at the extreme positions on the left and right.

Potential and kinetic energy The energy of the vibrating system (the cart and spring) varies between maximum potential energy when at the extreme positions to maximum kinetic energy as the object passes equilibrium. In between, the energy is a combination of kinetic and potential energy.

In Table 10.2, the acceleration of the cart and the force that the spring exerted on the cart were greatest at its extreme positions—at $x = \pm A$. This distance from the equilibrium position to an extreme position of the motion is called the **amplitude** of the vibration (**Figure 10.2**).

FIGURE 10.2 The cart vibrates between $+A$ and $-A$. The distance from the equilibrium position to A is called the amplitude of the vibration.



Amplitude The amplitude A of a vibration is the magnitude of the maximum displacement of the vibrating object from its equilibrium position.

The patterns described in the observational experiment tables are general features of vibrational motion. We summarize them below:

1. During vibrational motion, an object passes through the same positions, first moving in one direction and then in the opposite direction.
2. The object passes one position (the equilibrium position) at high speed, first in one direction, then the other. When it is not in the equilibrium position, a component of a restoring force exerted on it by some other object points back toward equilibrium.
3. A system composed of the vibrating object and the object exerting the restoring force has maximum potential energy when the vibrating object is at extreme positions $(x = \pm A)$. The system has maximum kinetic energy when the vibrating object is passing through the equilibrium position $(x = 0)$.

Many objects undergo vibrational motion: the strings of musical instruments, a drumhead, or keys on a key chain after you slam the door (see **Figure 10.3**). Vibrations are not always desirable. Tall buildings must be constructed so that they do not sway excessively during earthquakes or on very windy days, and cars must have shock absorbers to dampen the up-and-down vibrations that occur on a bumpy road. In other cases, vibrations are a desirable result: feel the surface of a speaker when music is playing.

FIGURE 10.3 Long-exposure photo of oscillating keys.

Period and frequency

Another important quantity is the time interval for one complete vibration. Consider the cart attached to a spring in Figure 10.2. The time interval for one complete vibration from $x = +A$ to $-A$ and back to $+A$ is called the **period** T of the vibration.

We are familiar with this quantity from our study of circular motion. For example, one day is the time interval (the period) for Earth to make one complete rotation on its axis—the time interval for the appearance of the Sun above the horizon on two consecutive mornings.

Period The period T of a vibrating object is the time interval needed for the object to make one complete vibration—from the clock reading when it passes through a position while moving in a certain direction until the next clock reading when it passes through that *same* position moving in the *same* direction. The SI unit of period is the second.

The number of vibrations each second is called the **frequency** f of the vibration. If an object makes 4 vibrations each second, the frequency is 4 vib/s and the period is 0.25 s. The most commonly used frequency unit is the hertz (Hz), where 1 hertz equals 1 vibration per second: 1 Hz = 1 vib/s (or 1 cycle/s). The words vibration and cycle indicate what is being counted but are not themselves units. These words (cycle and vibration) can be removed from the units in equations involving frequency. Thus, an appropriate unit for frequency is $1/\text{s}$ or s^{-1}.

Frequency The frequency f of vibrational motion is the number of complete vibrations of the system during one second. Frequency is related to period:

$$f = \frac{1}{T} \tag{10.1}$$

The SI unit for frequency is the hertz (Hz), where $1\ \text{Hz} = 1\ \text{vib/s} = 1\ \text{s}^{-1}$.

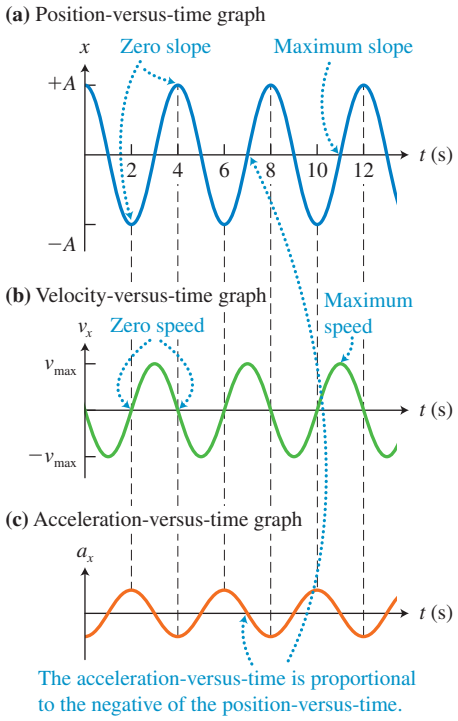
QUANTITATIVE EXERCISE 10.1 **The vibration of a building**

The Empire State Building sways back and forth in high wind at a vibration frequency of 0.125 Hz. What is its period of vibration? Does your answer make sense?

Represent mathematically Since we know the vibration frequency, we can determine the period $T = 1/f$.

Solve and evaluate The period is

$$T = \frac{1}{f} = \frac{1}{0.125\ \text{Hz}} = \frac{1}{0.125\ \text{vib/s}} = 8.0\ \text{s/vib} = 8.0\ \text{s}$$



We find that the period of vibration is rather long. Observations of the tower show that the amplitude of vibration at the top of the building in a high wind is less than 4 cm. The long period of vibration and relatively small amplitude mean that this vibration is unlikely to damage the building or affect its occupants.

Try it yourself You sit on a rocking chair. It takes 12 s to complete six rocks—all the way back and all the way forward again. Determine the period and the frequency of the rocking.

Answer 2.0 s period and 0.5 rocks/s $= 0.5\ \text{s}^{-1} = 0.5$ Hz frequency.

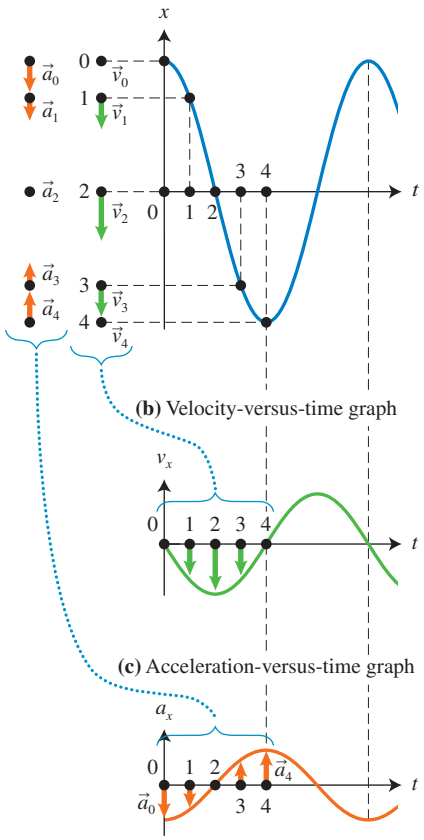
REVIEW QUESTION 10.1 Can we say that the period of vibration depends on the frequency or that the frequency depends on the period? Explain your answer.

FIGURE 10.4 Kinematics graphs for vibrational motion.

10.2 Kinematics of vibrational motion

To help describe vibrational motion quantitatively, let's look at the data from an experiment in which a motion detector collects position-versus-time, velocity-versus-time, and acceleration-versus-time data for a cart vibrating on a spring. Graphs of the data are shown in **Figure 10.4**.

The position of the object changes periodically, as does the slope of the graph. Note that the period for all three graphs is 4.0 s. Note also the relationship between the position and acceleration graphs. The acceleration has its maximum negative value when the position has its maximum positive value and vice versa. This makes sense. When the cart is at the rightmost positive x-position, the spring is exerting its maximum leftward negative x-force on the cart, causing maximum leftward negative acceleration.



Consistency of motion diagram and graphs

Is a motion diagram for vibrational motion consistent with the graphs in Figure 10.4? We can rotate the motion diagram in Table 10.2 so that it is oriented vertically beside a position-versus-time graph (**Figure 10.5a**) with the first five points numbered 0–4. We can move the $\vec{v}$ arrows from the motion diagram down to the velocity-versus-time graph (Figure 10.5b) and the $\vec{a}$ arrows from the diagram down to the acceleration-versus-time graph (Figure 10.5c). The graphs and the motion diagram are consistent with each other.

Notice also that the three graphs in Figure 10.4 are consistent with each other. Recall that velocity is the rate of change of position $v_x = (\Delta x/\Delta t)$—the slope of the position-versus-time graph. The velocity has its maximum positive value when the position-versus-time graph has its maximum positive slope. The slope of the position-versus-time graph is zero when $x = A$, as is the velocity. Note that at other clock readings, the slope of the position-versus-time graph has the same sign and relative magnitude as the reading of the velocity-versus-time graph.

Recall that acceleration is the rate of change of velocity $a_x = (\Delta v_x/\Delta t)$. The acceleration-versus-time graph is also consistent with the velocity-versus-time graph. For example, the acceleration is maximum when the velocity-versus-time graph has its maximum slope at $t = 2$ s and 6 s. The acceleration is zero when the slope of the velocity-versus-time graph is zero at $t = 3$ s.

FIGURE 10.5 The motion diagram and kinematics graphs are consistent with each other.

Mathematical description of position as a function of time

Our goal now is to devise a periodic mathematical function whose graphical representation is similar to the graphs shown in Figure 10.4. What kind of function would work? The function should be periodic and vary between the amplitude of the vibrations and the amplitude with the negative sign. It should have zero value twice during one period.

Sinusoidal functions (in which the value of the function is proportional to the sin or cos of an angle) are the simplest periodic functions. The meanings of sine and cosine can be best understood using a unit circle (**Figure 10.6**) whose **radius vector** has a length of 1 unit and makes an angle θ with the x-axis (Figure 10.6a). We can then resolve the radius vector into its x- and y-components (Figure 10.6b):

$$r_x = r\cos\theta = (1)\cos\theta = \cos\theta$$
$$r_y = r\sin\theta = (1)\sin\theta = \sin\theta$$

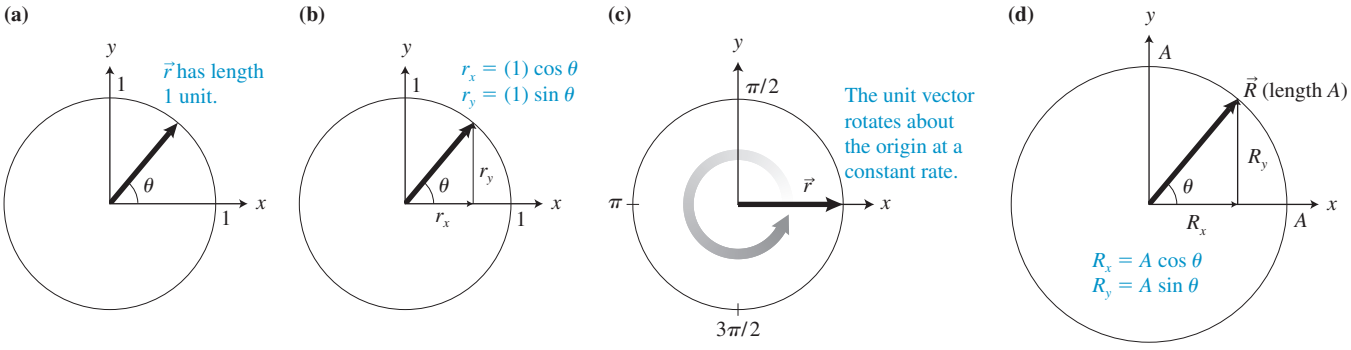
Imagine now that the radius vector rotates counterclockwise around the origin of the coordinate system. The angle θ changes continuously from 0 to 360°, or from 0 to 2π rad. Consequently, the x-component of the radius vector changes from +1 to 0 to −1 to 0 and then back to +1; the y-component changes from 0 to +1 to 0 to −1 and then back to 0 (Figure 10.6c). If the radius vector continues rotating, the functions cos θ and sin θ become periodic functions with period 2π rad, or 360°.

If instead of a unit circle, you have a circle of radius A, the rotating radius vector will now have components:

$$R_x = A\cos\theta$$
$$R_y = A\sin\theta$$

as in Figure 10.6d. In these functions A is the maximum value or amplitude of the function, and θ is an angle that changes by 2π radians (2π rad = 360°) during each period of the function. We can think of R_x and R_y as the functions $x = A\cos\theta$ and

FIGURE 10.6 (a–c) A unit circle used to define the cos and sin functions and (d) a circle of radius A used to define sinusoidal functions.



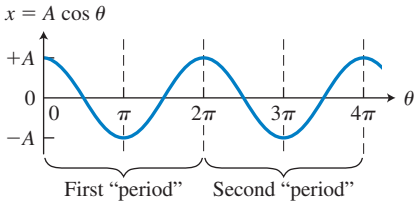


FIGURE 10.7 A graph of an $A \cos \theta$ function.

This graph has the same shape as the position-versus-time graph in Figure 10.4a.

$y = A \sin \theta$. A graph of $x = A \cos \theta$, shown in **Figure 10.7**, looks very similar to the position-versus-time graph produced by the motion detector shown in Figure 10.4a. However, in Figure 10.7 the independent variable is the angle θ, not the time t. We need a sinusoidal function of time to describe the motion of a vibrating object.

In **Table 10.3**, we compare the changes in position of the vibrating object as a function of clock reading shown in Figure 10.4a and the changes in position as a function of angle of the sinusoidal function shown in Figure 10.6d.

TABLE 10.3 Position of a vibrating object as a function of time

Clock reading t of the vibrating object shown in Figure 10.4a	Position x of the vibrating object shown in Figure 10.4a	Angle of the radius vector θ (radians) for the function $x = A \cos \theta$	Value of the function $x = A \cos \theta$
0 (0 s)	A	0	A
$\frac{1}{4}T$ (1 s)	0	$\pi/2$	0
$\frac{1}{2}T$ (2 s)	$-A$	π	$-A$
$\frac{3}{4}T$ (3 s)	0	$3\pi/2$	0
T (4 s)	A	2π	A
$2T$ (8 s)	A	4π	A
$3T$ (12 s)	A	6π	A

The function $x = A \cos \theta$ matches the actual vibrational motion well. If we compare more times, the match remains strong. Now, we just need to replace θ with an appropriate function of time. Let's take the ratio of the angle and clock reading at any of the clock readings listed in the table. For example,

$$\frac{\theta}{t} = \frac{2\pi}{T}$$

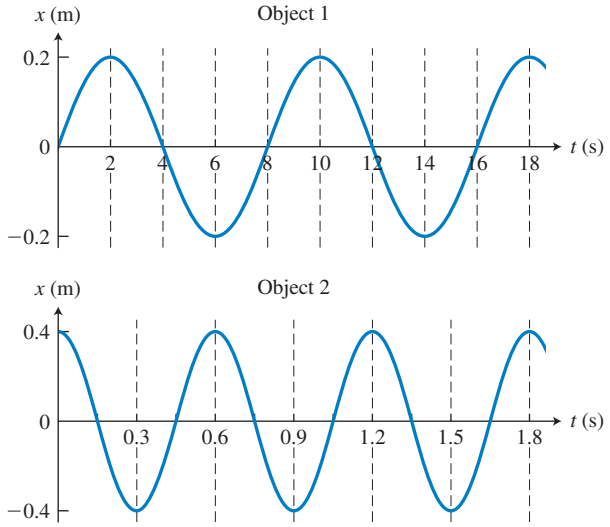
or

$$\theta = \left(\frac{2\pi}{T}t\right)$$

We can write a periodic function $x(t)$ to represent the position-versus-time graph:

$$x = A \cos\left(\frac{2\pi}{T}t\right) \tag{10.2}$$

Notice that the above function has $x = +A$ at $t = 0$. If an object is at $x = 0$ at $t = 0$, you can either adjust the cos function by adding $-(\pi/2)$ or use the sine function to describe the motion:



$$x = A \sin\left(\frac{2\pi}{T}t\right)$$

since $\sin \theta = \cos\left(\theta - \frac{\pi}{2}\right)$.

Model of simple harmonic motion Motion described by Eq. (10.2) is called **simple harmonic motion** (SHM) since the cosine and sine functions are known as harmonic functions. SHM is a *mathematical model* of motion. Based on position-versus-time graphs, we see that a cart attached to a spring undergoes motion that is similar to SHM.

QUANTITATIVE EXERCISE 10.2 **Describing the motion of two objects**

The graphical descriptions of the vibrational motions of two objects are shown in the figure. Write mathematical descriptions (equations) for these motions.

Represent mathematically (a) Vibrating object 1 has its maximum displacement of $A_1 = 0.2$ m and a period $T_1 = 8$ s. At time 0 the object is at zero and then its position increases. Thus, the function that describes its motion is a sine function:

$$x_1 = A_1 \sin\left(\frac{2\pi}{T_1}t\right)$$

Alternatively, we could write it as

$$x_1 = A_1 \cos\left(\frac{2\pi}{T_1}t - \frac{\pi}{2}\right)$$

(b) Vibrating object 2 has a maximum displacement $A_2 = 0.4$ m at time zero and has period $T_2 = 0.6$ s. Thus, the function

$$x_2 = A_2 \cos\left(\frac{2\pi}{T_2}t\right)$$

describes its motion. Alternatively, we could write it as

$$x_2 = A_2 \sin\left(\frac{2\pi}{T_2}t + \frac{\pi}{2}\right)$$

Solve and evaluate The mathematical description of vibrating object 1 is

$$x_1 = (0.2\text{ m}) \sin\left(\frac{2\pi}{8\text{ s}}t\right)$$

The mathematical description of vibrating object 2 is

$$x_2 = (0.4\text{ m}) \cos\left(\frac{2\pi}{0.6\text{ s}}t\right)$$

Try it yourself Write a mathematical description for the displacement of an object that has amplitude 0.10 m and frequency of 5.0 Hz, and starts vibrating from position $x = -A$.

Answer

$x = -(0.10\text{ m}) \cos\left(\frac{2\pi}{0.20\text{ s}}t\right)$. Note that the period is $T = \frac{1}{f} = \frac{1}{5.0\text{ s}^{-1}} = 0.20\text{ s}$.

Mathematical description of velocity and acceleration as a function of time

We see in Figure 10.4 that the position-, velocity-, and acceleration-versus-time graphs are all sinusoidal. They have the same period but have different amplitudes and reach their respective maxima and minima at different clock readings. We discussed the qualitative relationships among the three graphs earlier in this section. What are the mathematical descriptions of the three functions? When you have a function of time, you can find its rate of change by taking the derivative of the function. Those operations are studied in calculus; we will not show them in this book but will provide you with the final results. If the position function is given by Eq. (10.2)

$$x = A \cos\left(\frac{2\pi}{T}t\right)$$

then the velocity and acceleration functions are

$$v_x = -\left(\frac{2\pi}{T}\right) A \sin\left(\frac{2\pi}{T}t\right) \tag{10.3}$$

$$a_x = -\left(\frac{2\pi}{T}\right)^2 A \cos\left(\frac{2\pi}{T}t\right) \tag{10.4}$$

TIP Instead of the cosine in Eq. (10.2), you can represent the position of the object as a sine function (see Quantitative Exercise 10.2). This replacement will change the argument (or the independent variable) of the function but will not change the relationship between position, velocity, and acceleration. The velocity function will be a cosine and the acceleration will be a sine function again, but with a negative sign.

where A is the amplitude of the vibration and T is the period of the vibration. Notice that the velocity function has amplitude $(2\pi/T)A$ while the acceleration function has amplitude $(2\pi/T)^2A$. Note also that the function for acceleration looks exactly the same as the function for position multiplied by $-(2\pi/T)^2$. We can say that the acceleration of a vibrating object is directly proportional to its displacement from equilibrium. Specifically, $a_x = -(2\pi/T)^2x$. Finally, we see that the clock readings when the velocity and acceleration reach their respective maxima and minima match those in Figure 10.4.

QUANTITATIVE EXERCISE 10.3 **Equation Jeopardy**

The position of a vibrating cart attached to a spring is described by the equation

$$x = (0.050\text{ m})\cos[(12\text{ s}^{-1})t]$$

What can you determine about the motion?

Represent mathematically Compare the above equation with the position-versus-time equation for simple harmonic motion: $x = A\cos\left(\frac{2\pi}{T}t\right)$. We see that the amplitude A of the vibration is 0.050 m and $\frac{2\pi}{T} = 12\text{ s}^{-1}$. The period is then $T = (2\pi/12)\text{ s} = (\pi/6)\text{ s}$. The frequency of vibration is $f = 1/T = (6/\pi)\text{ s}^{-1} = (6/\pi)\text{ Hz}$. The object has its maximum positive displacement at time zero.

Solve and evaluate The velocity of the vibrating cart is

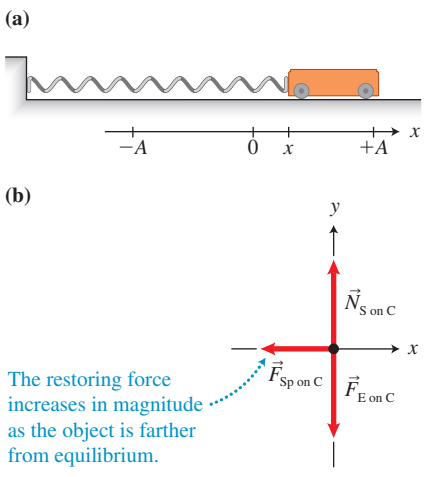
$$v_x = -\frac{2\pi}{(\pi/6)\text{ s}}(0.050\text{ m})\sin\left[\frac{2\pi}{(\pi/6)\text{ s}}t\right]$$
$$= -(0.60\text{ m/s})\sin[(12\text{ s}^{-1})t]$$

The amplitude of the velocity (the cart's maximum speed) is 0.60 m/s. The cart's acceleration is

$$a_x = -\left[\frac{2\pi}{(\pi/6)\text{ s}}\right]^2(0.050\text{ m})\cos\left[\frac{2\pi}{(\pi/6)\text{ s}}t\right]$$
$$= -(7.2\text{ m/s}^2)\cos[(12\text{ s}^{-1})t]$$

The amplitude of the acceleration (the cart's maximum acceleration) is 7.2 m/s^2.

Try it yourself Suppose the amplitude of vibration in this exercise remained the same, but the period was reduced by half. By what factors would this affect the cart's maximum speed and maximum acceleration? Try to answer without plugging numbers into equations.



Answer Since the maximum speed is proportional to $1/T$, the maximum speed would double if the period were halved. Since the maximum acceleration is proportional to $1/T^2$, the maximum acceleration would quadruple if the period were halved.

REVIEW QUESTION 10.2 The velocity of an object attached to a spring changes as

$$v_x = -(0.84\text{ m/s})\sin[(4.19\text{ s}^{-1})t]$$

Say all you can about its motion.

FIGURE 10.8 Dynamics of simple harmonic motion.

10.3 Dynamics of simple harmonic motion

So far, we have described simple harmonic motion (SHM) using sketches, motion diagrams, kinematics graphs, and kinematics equations. Now we will investigate the mechanism behind SHM.

Forces and acceleration

Consider again a cart on a frictionless surface attached to a spring (**Figure 10.8a**). We use a light (massless) spring that when stretched exerts a force on the cart. According to Hooke's law, that force is $F_{Sp\text{ on }C\,x} = -kx$. Position x is equal to the displacement of the end of the spring from its unstretched position to where it is attached to the cart. The other end of the spring is fixed. When the cart is at position x relative to the unstretched

equilibrium position, the spring exerts a restoring force on the cart (the object) that pulls it toward the equilibrium position (Figure 10.8b). The force component along the x-direction is

$$F_{\text{Sp on C}\,x} = -kx \tag{10.5}$$

The spring is the only object that exerts a force with a nonzero x-component on the cart. Thus, the x-component form of Newton's second law ($a_x = \Sigma F_x/m$) becomes

$$a_x = \frac{-kx}{m} = -\frac{k}{m}x \tag{10.6}$$

where m is the mass of the cart. The above expression shows that the cart's acceleration a_x is proportional to the negative of its displacement x from the equilibrium position. This is exactly how the displacement and acceleration of an object undergoing SHM are related [Eq. (10.4)]. If the cart is on the positive side of the equilibrium position, the spring pulls it in the negative direction so that its acceleration component is negative. If the cart is on the negative side of the equilibrium position, the spring pushes it in the positive direction so its acceleration component is positive. Note that the farther the cart is from equilibrium, the greater the magnitude of the force that the spring exerts on the cart and the greater the magnitude of the cart's resulting acceleration.

We now understand *why* the acceleration-versus-time graph in Figure 10.4c is the same shape as the position-versus-time graph in Figure 10.4a with the sign of a being opposite the sign of x at all times; the restoring force exerted on the vibrating object is proportional to the displacement of the object from equilibrium but opposite in direction. Whenever this relation holds for a system, that system's motion can be described mathematically as simple harmonic motion.

Stop for a moment and think how unusual Eq. (10.6) is. When we studied linear motion at constant acceleration (Chapter 2), the acceleration of a moving object was the same at any location and did not depend on the position. When we studied constant speed circular motion (Chapter 5), the direction of acceleration changed with changing position along the circle, but the magnitude remained the same. In SHM the acceleration of an object changes in time in both magnitude and direction but is synchronized with the displacement of the object. Thus the sum of the forces exerted on an object moving in a circle at constant speed is constant in magnitude and only changes direction (it always points toward the center of the circle). The sum of the forces exerted on an object undergoing SHM not only changes direction during the motion but also changes magnitude.

Period of vibration of a cart attached to a spring

We now understand that Eq. (10.6) explains the relationship between the position and the acceleration of the cart. Can it also explain the frequency or period of vibration of a spring-cart system? What properties of a vibrating system affect the period of the vibration? Intuitively, you probably think that the period depends on the amplitude—the larger the amplitude, the longer it should take the cart to go through a full cycle. This is easy to check by simply starting the vibration with various amplitudes. We find that the period is essentially constant even when the amplitude is doubled or tripled (provided the amplitude is not too large). This seems surprising, but on reflection is reasonable. The farther we pull the cart from its equilibrium position, the greater the elastic force exerted on it by the spring, the greater the acceleration of the cart, and the faster it moves toward the equilibrium position. Thus it moves faster but over a longer distance—the two effects compensate. The period is independent of the amplitude.

Two other factors could affect the period of the vibration. The stiffness of the spring should make a difference, because a stiffer spring pulls harder on the cart, increasing the acceleration of the cart. The mass of the cart should also affect the period, as a more massive cart is harder to accelerate. We can use Newton's second law [Eq. (10.6)] and

the kinematics equations that describe position and acceleration to derive an expression for the period of vibration of a cart with mass m at the end of a spring of spring constant k. We start with Eq. (10.6):

$$a_x = -\frac{k}{m}x$$

Substitute the expressions for x and a_x [Eqs. (10.2) and (10.4)] in the above to get

$$-\left(\frac{2\pi}{T}\right)^2 A\cos\left(\frac{2\pi}{T}t\right) = -\frac{k}{m}A\cos\left(\frac{2\pi}{T}t\right)$$

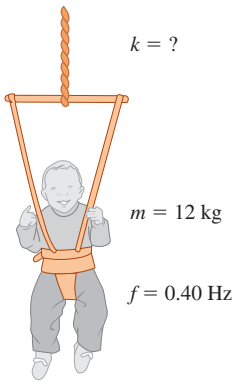
Divide both sides of the equation by $-A\cos\left(\frac{2\pi}{T}t\right)$ and solve for T:

$$\left(\frac{2\pi}{T}\right)^2 = \frac{k}{m} \quad \Rightarrow 4\pi^2\frac{m}{k} = T^2$$

Thus, the period is

$$T = 2\pi\sqrt{\frac{m}{k}} \tag{10.7}$$

Notice that in this expression for period, there is no dependency on the amplitude. We can also check the units: $\sqrt{\frac{\text{kg}}{\text{N/m}}} = \sqrt{\frac{(\text{kg}\times\text{m})\text{s}^2}{\text{kg}\times\text{m}}} = \text{s}$, the correct unit for period. The frequency f of vibration of an object attached to a spring is $\frac{1}{T}$, or



$$f = \frac{1}{2\pi}\sqrt{\frac{k}{m}} \tag{10.8}$$

In our derivation we assumed that the spring obeys Hooke's law, that the spring has zero mass, and that the cart is a point-like object. We also neglected friction. In real life, most springs obey Hooke's law if you do not stretch them too far, but it is impossible to find a massless spring or to eliminate frictional effects entirely. However, even with these assumptions, the above equation agrees closely with experiments in which friction is minimal and the mass of the spring is small compared with the mass of the attached object (see the video).

VIDEO 10.1

QUANTITATIVE EXERCISE 10.4 Vibrating chair

You want to design a bouncy seat for your nephew using a bungee cord (see figure at right). The chair should allow a 12-kg baby (including the mass of the seat) to bounce up and down naturally at a frequency of about 0.40 Hz. Estimate the spring constant the cord should have.

Represent mathematically Model the cord as a linear spring and the child + seat as a point-like object. We know the requested vibration frequency and the proposed mass of the child and seat. We can use Eq. (10.8) to find k:

$$f = \frac{1}{2\pi}\sqrt{\frac{k}{m}}$$

Solve and evaluate Square both sides of the above equation to get $f^2 = (1/4\pi^2)(k/m)$. Then, multiplying both sides by $4\pi^2 m$, we have

$$k = 4\pi^2 m f^2 = 4\pi^2(12\text{ kg})(0.4\text{ s}^{-1})^2$$
$$\simeq 80\text{ kg/s}^2 = 80\text{ N/m}$$

Try it yourself If the total mass of the child + seat were increased to 24 kg without changing the spring constant, what would be the frequency of vibration? Describe any additional difficulties that would result from this change.

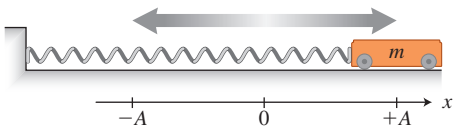
Answer

$f = 0.28\text{ s}^{-1}$ or $T = 3.5$ s. The cord would stretch twice as far—it may not fit in a doorway.

REVIEW QUESTION 10.3 What will happen to the period of a cart on a spring if you attach a second spring next to the first one in parallel, making two of them pull on the cart together?

10.4 Energy of vibrational systems

So far we have used the force approach to analyze the motion of vibrational systems quantitatively. Let us investigate how the energy approach can help us understand the process better. Consider again the vibration of a cart at the end of a spring (our system). The cart starts one vibration cycle at time $t = 0$ at position $x = +A$.



As the cart-spring system vibrates, the energy of the system continuously changes from all elastic when at $x = +A$ to all kinetic when passing through the equilibrium position at $x = 0$ to all elastic again when stopping for an instant at the far left of the vibration at $x = -A$ (see the far right column of **Table 10.4**). The cycle repeats on the way back to its starting position. Thus, the energy cycles between elastic and kinetic twice during each period. Assuming that no external forces do work on the system, the system's total energy is constant. Its value equals the maximum elastic potential energy when at $x = \pm A$, the maximum kinetic energy when at $x = 0$, and some combination of the two at other positions.

$$E = \tfrac{1}{2}kA^2 = \tfrac{1}{2}mv_{\max}^2 = \tfrac{1}{2}mv^2 + \tfrac{1}{2}kx^2 \qquad (10.9)$$

Notice that Table 10.4 shows only the states in which the system possesses either only elastic potential energy or only kinetic energy. These states are grouped together. In all other states (not shown in the table due to their infinite number), the system possesses some combination of both energies.

TABLE 10.4 Variation of energy during one vibration

Clock reading t	Displacement	Elastic potential energy U_s	Kinetic energy K	Total energy E_{tot}
$\frac{1}{2}T$	$-A$	$\frac{1}{2}kA^2$	0	$E_{tot} = \frac{1}{2}kA^2$
$\frac{1}{4}T$	0	0	$\frac{1}{2}mv_{\max}^2$	$E_{tot} = \frac{1}{2}mv_{\max}^2$
$\frac{3}{4}T$	0	0	$\frac{1}{2}mv_{\max}^2$	
0	A	$\frac{1}{2}kA^2$	0	$E_{tot} = \frac{1}{2}kA^2$
T	A	$\frac{1}{2}kA^2$	0	

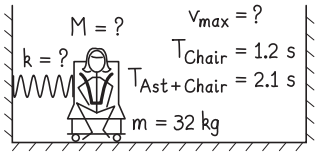
The second equality in Eq. (10.9) can be rearranged to give a relationship between the amplitude of the vibration and the cart's maximum speed:

$$v_{\max} = \sqrt{\frac{k}{m}}A \qquad (10.10)$$

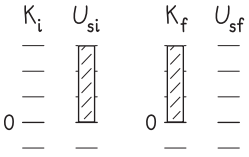
This is exactly what follows from the kinematics equations describing simple harmonic motion [Eqs. (10.2) and (10.3)]. It also makes sense conceptually: when the mass of the cart is large, it should move slowly through the equilibrium position—having the mass in the denominator makes sense. If the spring is stiff, the cart will move faster—having the spring constant in the numerator also makes sense.

TIP In this discussion we neglected the interactions of the system with the surface of the track and with the air. If we take these interactions into account and include the surface and air in the system, the mechanical energy of the system will be converted into internal energy, eventually bringing the vibrating system to rest.

FIGURE 10.9 An astronaut Body Mass Measurement Device.



Astronauts in space can lose significant body mass because their muscles do not get sufficient use and begin to atrophy. Since traditional scales do not function in orbit (both the scale and the astronaut are in free fall), NASA developed the Body Mass Measurement Device (BMMD) to monitor the astronauts' mass. The BMMD consists of a chair on which the astronaut sits (**Figure 10.9**). A spring holds the chair in place. When the chair is pulled back and released, it vibrates at a frequency that depends on the mass of the chair plus astronaut.



EXAMPLE 10.5 Astronaut mass

The BMMD chair (mass 32 kg) has a vibrational period of 1.2 s when empty. When an astronaut sits on the chair, the period changes to 2.1 s. Determine (a) the effective spring constant of the chair's spring, (b) the mass of the astronaut, and (c) the maximum vibrational speed of the astronaut if the amplitude of vibration is 0.10 m.

Sketch and translate We choose the chair and the spring as the system for (a) and the astronaut, chair, and spring for (b) and (c).

Simplify and diagram Assume that the chair's spring obeys Hooke's law and that the spring's mass is much smaller than the mass of the chair plus astronaut. We determine the effective spring constant as though there were one spring pushing and pulling the chair. For (c) we represent the process using a bar chart starting from the state when the chair is pulled the farthest from equilibrium and ending as the chair and person pass equilibrium.

Represent mathematically (a) Use $T_{\text{Chair}} = 2\pi\sqrt{\frac{m}{k}}$ to determine the spring constant with the chair empty.

(b) Use $T_{\text{Ast+Chair}} = 2\pi\sqrt{\frac{m+M}{k}}$ to determine the astronaut mass.

(c) Determine the energy in the spring-astronaut-chair system when at the extreme position $x = +A$: $E = \frac{1}{2}kA^2$. Then use this energy to determine the maximum speed as the cart passes through equilibrium using $E = \frac{1}{2}kA^2 = \frac{1}{2}(m+M)v_{\max}^2$.

Solve and evaluate (a) Square $T_{\text{Chair}} = 2\pi\sqrt{\frac{m}{k}}$ or $T_{\text{Chair}}^2 = 4\pi^2\frac{m}{k}$. Rearrange to get

$$k = 4\pi^2\frac{m}{T_{\text{Chair}}^2} = 4\pi^2\frac{32\text{ kg}}{(1.2\text{ s})^2} = 877\text{ N/m}$$

(b) Square $T_{\text{Ast+Chair}} = 2\pi\sqrt{\frac{m+M}{k}}$ or $T_{\text{Ast+Chair}}^2 = 4\pi^2\frac{m+M}{k}$. Rearrange to get

$$m + M = \frac{T_{\text{Ast+Chair}}^2 k}{4\pi^2} \quad \text{or} \quad M = \frac{(2.1\text{ s})^2(877\text{ N/m})}{4\pi^2} - 32\text{ kg} = 66\text{ kg}$$

(c) From $E = \frac{1}{2}kA^2 = \frac{1}{2}(m+M)v_{\max}^2$, $kA^2 = (m+M)v_{\max}^2$.

$$\text{Thus } v_{\max} = A\sqrt{\frac{k}{m+M}} = (0.10\text{ m})\sqrt{\frac{(877\text{ N/m})}{32\text{ kg} + 66\text{ kg}}} = 0.30\text{ m/s}.$$

$$\text{Check the units: m}\sqrt{\frac{\text{N/m}}{\text{kg}}} = \sqrt{\frac{\text{m}^2(\text{N/m})}{\text{kg}}} = \sqrt{\frac{\text{m(kg} \times \text{m)}}{\text{kg} \times \text{s}^2}} = \text{m/s}.$$

The units are correct. The magnitudes are reasonable—a person can have a mass of 66 kg, and the speed of 0.3 m/s is a realistic speed for such a process.

Try it yourself What would be the period of vibration of the machine if used by an 80-kg astronaut?

Answer About 2.2 s.

REVIEW QUESTION 10.4 The period of vibration of a cart on a spring is 2.0 s. The elastic potential energy fluctuates in a repetitive pattern. What is the period of the elastic potential energy variation of the system? What is the period of the total energy of the system?

10.5 The simple pendulum

Springs are common in many objects that we use every day; they are an important component of mattresses, doors, shock absorbers, and office chairs. However, we seldom observe the springs themselves—most of them are hidden. One vibrating system in which the motion is very apparent is a pendulum. Grandfather clocks and mechanical metronomes use pendulums, of course. Another version of a pendulum is the oscillating movement of our arms and legs when we walk. In fact, much of animal locomotion involves complicated pendulum-like motions. Imagine a walking giraffe—its long legs swing as it walks. For now, let's consider a simplified model of a pendulum system that has a compact object (called a *bob*) at the end of a comparatively long and massless string and undergoes small amplitude vibrations. This idealized system is called a **simple pendulum**.

When the bob shown in **Figure 10.10** hangs straight down at rest, the sum of the forces exerted on it is zero. This is the equilibrium position for the bob. If you pull the bob to the right side (Figure 10.10a) and release it, it swings to the left (Figure 10.10b), overshooting the equilibrium position (Figure 10.10c), and then stops briefly at about the same distance to the left as it started on the right. The bob then swings back toward the equilibrium position, overshoots, stops about where it started and the motion repeats again. The pendulum undergoes circular motion with changing speed.

Two objects interact with the bob of the pendulum. The string S exerts a force in the radial direction that is always perpendicular to the path of the bob. Earth exerts a downward gravitational force that we can resolve into a radial component r along the string and a tangential component t perpendicular to the string. The tangential component of the force exerted by Earth on the bob points toward the equilibrium position—toward the left when the bob is on the right side of equilibrium (Figure 10.10b) and toward the right when on the left side (Figure 10.10d). This component of the gravitational force is what is always trying to restore the pendulum bob to its equilibrium position.

However, the tangential component of the force exerted by Earth on the bob is not equal to the sum of the forces exerted on the bob. Figure 10.10d shows an intermediate position of the bob. In this position you can see clearly that the sum of the forces does not point toward the equilibrium position, but the tangential component of the force exerted by Earth does. Hence, the tangential component of the gravitational force exerted by Earth on the bob is the restoring force. Thus, the ideas of equilibrium position and restoring force also apply to the vibrational motion of a pendulum. The bar charts in the figure also show the conversion of the bob-Earth system's energy from potential to kinetic, similar to the energy conversions for a cart attached to a spring.

FIGURE 10.10 Analyzing the forces exerted on a pendulum bob during pendulum motion.

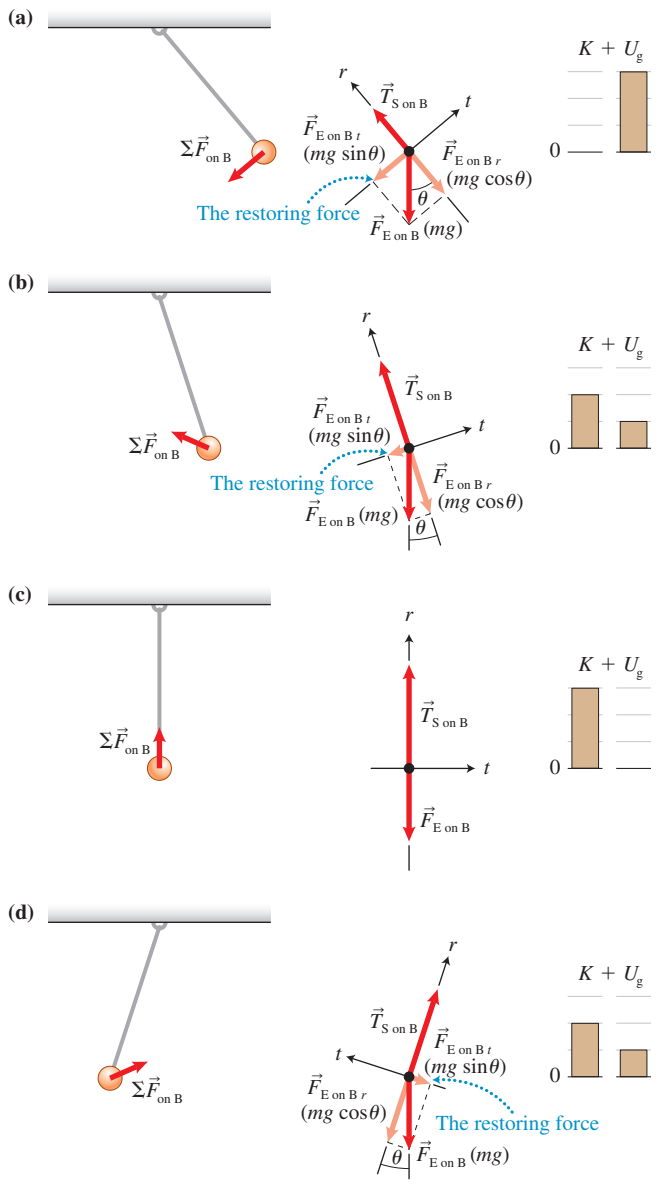


TABLE 10.5 Effect of bob mass, string length, and amplitude on pendulum period

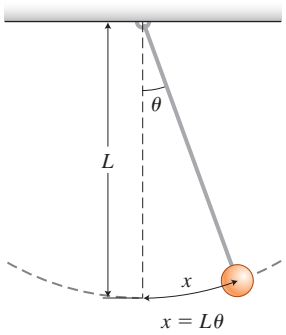
Bob mass m (kg)	String length L (m)	Amplitude θ (°)	Period T (s)
1.0	1.0	10.0	2.0
2.0	1.0	10.0	2.0
3.0	1.0	10.0	2.0
1.0	**2.0**	10.0	2.8
1.0	**3.0**	10.0	3.5
1.0	**4.0**	10.0	4.0
1.0	1.0	**15.0**	2.0
1.0	1.0	**20.0**	2.0
1.0	1.0	**25.0**	2.0

Experimental investigation of the period T of a simple pendulum

To investigate how the properties of a simple pendulum affect the period, we record its period for different vibration amplitudes A, bob masses m, and string lengths L (changing them one at a time). The results appear in **Table 10.5**. Notice that for the pendulum the amplitude of the angular displacement is measured in terms of the angle θ that the string makes with the vertical direction. Quantities that have been changed are boldfaced.



It appears that the period depends only on the string length. It does not depend on the mass of the bob or the amplitude of vibration. Let's make a formal derivation of the period and see if it agrees with the above.

Deriving the period T of a simple pendulum

Suppose that the pendulum string has an angular displacement θ from the vertical—positive to the right and negative to the left (Figure 10.10). We already know that the string exerts a force on the bob that only has a radial component (see Figures 10.10b and c). The force exerted by Earth can be resolved into radial and tangential components. The radial component of magnitude $F_{\text{E on B}\,r} = -mg\cos\theta$ is along the radial axis and points outward, away from the center of the circle. The two radial components provide the bob with the radial acceleration necessary to keep the bob following a circular path. The tangential component of magnitude $F_{\text{E on B}\,t} = -mg\sin\theta$ serves as a restoring force (it is responsible for the change in the bob's speed along the arc). The negative sign indicates that the restoring force points opposite the direction of the angular displacement and back toward the equilibrium position.

Note that for small angles, the value of $\sin\theta$ is approximately equal to the value of θ (you can check this using your calculator). For example, when $\theta = 0.3491$ radians (equal to 20°), $\sin\theta = 0.3420$. θ and $\sin\theta$ differ by only 2%, even for this moderately large angle. Because $\theta \approx \sin\theta$ for small angles, the restoring force can be written as $F_{\text{E on B}\,t} = -mg\,\theta$, where θ must be in radians.

FIGURE 10.11 The linear displacement x of the bob is related to the string's angular displacement θ and length L.

The angular displacement θ is related to the linear position x along the arc of the swinging bob (the solid line on the arc in **Figure 10.11**):

$$x = L\theta$$

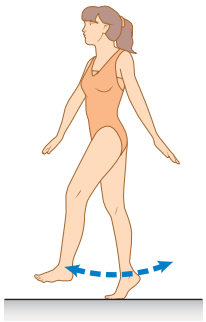
where L is the length of the pendulum string. Thus, we find that the tangential component of the restoring force is

$$F_{\text{E on B}\,t} = -mg\,\theta = -mg\left(\frac{x}{L}\right) = -\left(\frac{mg}{L}\right)x \qquad (10.11)$$

Equation (10.11) for the restoring force exerted on a vibrating pendulum bob is very similar to the restoring force exerted on a mass at the end of a spring ($F_x = -kx$); the only difference is that the spring constant k for a spring has been replaced by mg/L. Since the restoring force is directly proportional to the bob's displacement from equilibrium, the bob is in simple harmonic motion. Consequently, the period of a pendulum is given by Eq. (10.7) with mg/L replacing k:

$$T = 2\pi\sqrt{\frac{m}{k}} = 2\pi\sqrt{\frac{m}{mg/L}} = 2\pi\sqrt{\frac{L}{g}}$$

Thus, the period of a pendulum is



$$T = 2\pi\sqrt{\frac{L}{g}} \qquad (10.12)$$

Notice that the period of a simple pendulum depends only on its length and on the magnitude of the gravitational constant. It does not depend on the mass of the object

hanging at its end or on the amplitude of vibration. This agrees with the patterns we discovered in Table 10.5. The restoring gravitational force is proportional to the bob's mass, while the bob's acceleration $a_t = \Sigma F_t/m = -mg\theta/m$ is inversely proportional to its mass. Since mass cancels in the equation, the pendulum's motion does not depend on the bob's mass.

EXAMPLE 10.6 **Leg swinging period**

Estimate the number of steps that is "natural" for a leg to take per second while walking: in other words, the natural swinging frequency of the leg. We will treat the leg as a rigid body and model it as a simple pendulum.[1] The calculations in this example are approximate.

Sketch and translate Imagine a leg that is about 1 m long swinging like a pendulum from the hip. To estimate the frequency, the only thing we need to know is the length of the pendulum.

Simplify and diagram Although the leg swings as a pendulum, it does not resemble a simple pendulum since its mass is concentrated not at the foot but can be thought to be concentrated at the center of mass of the leg. We'll assume that the center of mass of the leg is at the knee and that the knee is at the midpoint of the leg.

Represent mathematically If a leg is 1 m long, then $L = 0.5$ m and its natural swinging frequency is calculated using Eq. (10.12).

$$f = \frac{1}{T} = \frac{1}{2\pi}\sqrt{\frac{g}{L}}$$

[1]In actuality, the leg is not a simple pendulum but is an example of what is called a physical pendulum—an extended body that swings back and forth about a pivot point. The swinging period of a physical pendulum is $f = (1/2\pi)\sqrt{mgL/I}$, where L is the distance from the pivot point to its center of mass, m is its mass, and I is the rotational inertia of the pendulum about its pivot point.

Solve and evaluate Inserting the estimated length in the above, we get

$$f \approx \frac{1}{2\pi}\sqrt{\frac{9.8\ \text{m/s}^2}{0.5\ \text{m}}} = 0.7\ \text{s}^{-1}$$

The period of one step is the inverse of f, or 1.4 s. According to our analysis, it is natural to take one step with your right leg (or with your left leg) approximately each 1.4 s. To check if this estimate is close to the real value, you can stand on the toes of one foot and swing your other leg freely back and forth at what seems like its natural unforced frequency (see figure). Count the number of swings in 60 s. When you divide 60 s by this number, you have the period for one swing.

Longer legs have longer periods of vibration. Giraffes take relatively few steps per second because of their long legs (a low walking frequency). A small dog like a Chihuahua has short legs and a high walking frequency. Each leg of the dog in the photo at right takes about two steps for each step taken by the man.

Try it yourself What should happen to your walking frequency when you walk wearing ankle weights? Why?

Answer The natural swinging frequency should decrease as the center of mass of the leg is lower and the pendulum becomes longer.

REVIEW QUESTION 10.5 Your grandfather's pendulum clock is slow. How should you adjust the position of the bob to correct for this?

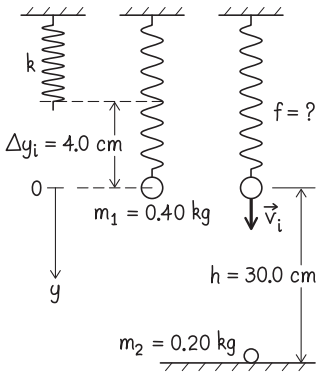
10.6 Skills for analyzing processes involving vibrational motion

We will now look at how to apply our general problem-solving strategy to solve problems involving vibrational motion. In addition to following the details of the steps, pay attention to the nature of the problem. It allows for two different answers depending on initial conditions.

PROBLEM-SOLVING STRATEGY 10.1 Analyzing vibrational motion

Sketch and translate

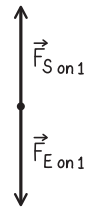
- Sketch the process described in the problem statement. Label known and unknown physical quantities.
- Visualize the processes described in the problem statement.
- Choose an object (or objects) as the system of interest. Depending on the process, you might need to analyze several systems.



Simplify and diagram

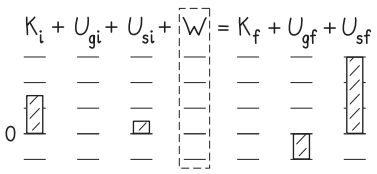
- Identify and evaluate assumptions and approximations.
- Represent the process with force diagrams and/or bar charts if needed.

EXAMPLE 10.7 **Vibrations of a vertical spring: a multiple possibility problem**



A long, light spring is hooked to the ceiling and hangs vertically. When we hang a 0.40-kg clay ball (ball 1) at the bottom end, the spring extends by 4.0 cm. A 0.20-kg clay ball (ball 2) rests on a table 30 cm below the hanging clay ball. You kick ball 1 down from its equilibrium position (you give the ball initial velocity). Determine the frequency of oscillations of the vibrating system.

We sketch the process and label the givens. From the sketch, we see that the problem has two possible outcomes depending on the initial velocity of ball 1. If the velocity is such that the amplitude of vibration of ball 1 is less than 30 cm, the period of vibrations will only depend on the mass of ball 1 and spring constant k of the spring. If the amplitude of vibration is greater than 30 cm, the vibrating ball 1 will hit the resting ball 2, they will stick together, and the frequency of the system will be lower. We need to consider both possibilities.



Because we do not know k for the spring, we first choose ball 1 as the system and do a force analysis to find k. Then we choose Earth, the spring, and ball 1 as the second system to do the amplitude analysis of the vibrating system. To determine the frequency, we need to take into account the mass of the system, which in turn depends on whether the amplitude of vibration is large enough for the balls to stick together. We will either proceed with the second system (if the amplitude is less than 30 cm) or include ball 2 in a new system (if the amplitude is larger than 30 cm). Therefore, we have two conditional answers for the frequency.

Assume that the spring obeys Hooke's law and that the spring's mass is much smaller than the masses of the balls. We also assume that the size of the balls is negligible. To determine the spring constant, we draw a force diagram for ball 1 when it is just hanging, before it is pulled down.

To calculate the initial amplitude of ball 1, we need to do an energy analysis of the process using a bar chart. We point the coordinate axis down and choose the zero level for the position and the gravitational potential energy to be at the equilibrium position. The initial state of the ball 1-Earth-spring system is when the spring is stretched and ball 1 is moving with initial velocity v_i through the equilibrium position. The final state is when ball 1 is in its lowest position and not moving (the position of ball 1 from equilibrium is A). The system has elastic potential energy and negative gravitational potential energy. The stretch of the spring is now $\Delta y_i + A$.

Represent mathematically

- If necessary, use kinematics equations to describe the changing motion of the object.
- If necessary, use the force diagrams to apply the component form of Newton's second law to the problem or use the bar charts to apply work-energy principles.
- If necessary, use the expressions for the period of an object attached to a spring or to a pendulum.

We use the force diagram for the hanging ball 1 to write Newton's second law and to find the spring constant of the spring:

$$m_1\vec{a} = \vec{F}_{\text{E on 1}} + \vec{F}_{\text{S on 1}}$$

Using the direction of the y-axis, the equilibrium condition (the ball is not accelerating), and the expressions for the two forces, we can rewrite Newton's second law as:

$$0 = m_1 g + (-k\Delta y_{\text{i}})$$

From this we can determine k:

$$k = \frac{m_1 g}{\Delta y_{\text{i}}}$$

We use the energy bar chart to write the mathematical representation of the process:

$$\tfrac{1}{2}k\Delta y_{\text{i}}^2 + \tfrac{1}{2}m_1 v_{\text{i}}^2 = \tfrac{1}{2}k(A + \Delta y_{\text{i}})^2 + (-m_1 g A)$$

$$\Rightarrow \tfrac{1}{2}k y_{\text{i}}^2 + \tfrac{1}{2}m_1 v_{\text{i}}^2 = \tfrac{1}{2}kA^2 + kAy_{\text{i}} + \tfrac{1}{2}k y_{\text{i}}^2 - m_1 g A$$

$$\Rightarrow \tfrac{1}{2}m_1 v_{\text{i}}^2 = \tfrac{1}{2}kA^2 + kA\Delta y_{\text{i}} - m_1 g A$$

Using the expression for k we found above,

$$kA\Delta y_{\text{i}} = \frac{m_1 g}{\Delta y_i} A\Delta y_{\text{i}} = m_1 g A$$

and thus the second term and the third term on the right side of the last energy equation add to zero. We now have $\frac{1}{2}m_1 v_{\text{i}}^2 = \frac{1}{2}kA^2$ and therefore the amplitude of the vibrations is equal to

$$A = v_{\text{i}}\sqrt{\frac{m_1}{k}}$$

This equation helps us find the value of the "critical" velocity that determines which of the two possibilities will occur. If $A < 30$ cm, only the mass of ball 1 will affect the frequency; if $A \geq 30$ cm, the frequency of the oscillations will be determined by the sum of the masses of ball 1 and ball 2. The amplitude will depend on the initial velocity of ball 1.

Solve and evaluate

- Solve for the unknowns.
- Evaluate the solution—is it reasonable? Consider the magnitude of the answer, its units, limiting cases, etc.

$$k = \frac{m_1 g}{\Delta y_{\text{i}}} = \frac{0.40\ \text{kg} \times 9.8\ \text{N/kg}}{0.040\ \text{m}} = 98.0\ \text{N/m}$$

$$A_{\text{critical}} = h = 0.30\ \text{m}$$

$$v_{\text{i critical}} = h\sqrt{\frac{k}{m_1}} = 0.30\ \text{m}\sqrt{\frac{98.0\ \text{N/m}}{0.40\ \text{kg}}} = 4.70\ \text{m/s}$$

Therefore, if the initial velocity of ball 1 is less than 4.70 m/s, the frequency of the system is

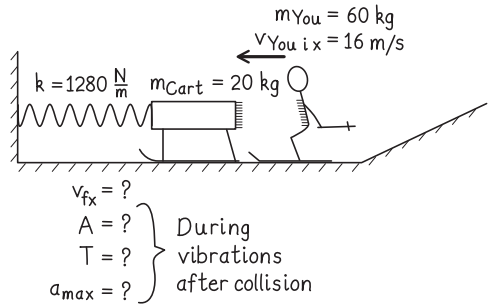
$$f_1 = \frac{1}{2\pi}\sqrt{\frac{k}{m_1}} = 2.49\ \text{Hz}$$

If the initial velocity of the ball is equal to or greater than 4.70 m/s, the frequency of the system is

$$f_1 = \frac{1}{2\pi}\sqrt{\frac{k}{m_1 + m_2}} = 2.03\ \text{Hz}$$

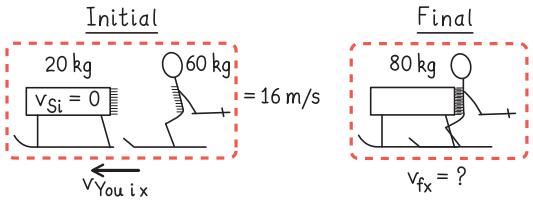
We expected the frequency to be smaller when the mass is larger. The magnitudes are reasonable—a system with a relatively stiff spring and relatively heavy object attached to it can reasonably make two oscillations every second.

Try it yourself What happens to the equilibrium position if ball 2 sticks to ball 1 and they start vibrating together?



Answer The new equilibrium position is 2.0 cm below the initial equilibrium position.

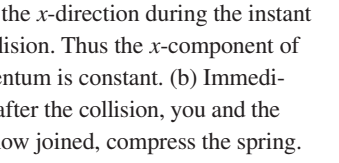
Note that the relation between velocity and amplitude, $A = v_i\sqrt{\frac{m_1}{k}}$, is exactly the same as that for the horizontal spring oscillator [see Eq. (10.10)]. This means that changing the orientation of a spring oscillator from horizontal to vertical does not affect its frequency or amplitude. However, it does affect the equilibrium position.

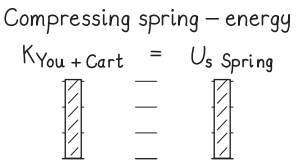


EXAMPLE 10.8 Skiing and vibrations

Imagine that you ski down a slope wearing a Velcro ski vest and then continue skiing on a horizontal surface at the bottom of the hill. There you run into a padded, Velcro-covered cart, which is also on skis (see the figure below). A 1280-N/m spring is attached to the other end of the cart and also to a wall. The spring compresses after your 60-kg body hits and sticks to the 20-kg cart. Your speed is 16 m/s just before you hit the cart. (a) What is your maximum speed after joining with the cart? (b) What is the maximum compression of the spring? (c) What is the period of the vibrational motion? (d) What is your maximum acceleration and where does it occur?

Sketch and translate Draw a labeled sketch.





(a) We represent the collision first (see the sketch below). The collision with the cart is a completely inelastic collision because you stick to the cart. If you and the cart are the system, then during the moment of the collision, the momentum of the system is constant (the same before and after the collision). We can use impulse-momentum ideas to determine your speed immediately after the collision.

(b) Now choose a different system: you, the cart, and the spring. The kinetic energy of you and the cart is converted into the spring's elastic potential energy as the spring compresses. (c) This is now a spring-object system that vibrates—you can determine the period of the vibration and the frequency. (d) The maximum acceleration is when the spring is compressed or stretched the most—when $x = \pm A$. We can determine the magnitude of the maximum acceleration using Newton's second law.

Simplify and diagram Assume that the snowy surface is perfectly smooth (zero friction), and that the spring has zero mass and obeys Hooke's law. (a) A momentum bar chart represents your collision with the cart (see the figure at right). There are no horizontal forces exerted on the you + cart system along the x-direction during the instant of collision. Thus the x-component of momentum is constant. (b) Immediately after the collision, you and the cart, now joined, compress the spring. An energy bar chart represents this process (see the figure at right).

Represent mathematically (a) Use momentum constancy for the collision with the cart to find the speed of you + cart after the collision:

$$m_{\text{You}}v_{\text{You i}\,x} + m_{\text{Cart}}v_{\text{Cart i}\,x} = m_{\text{You+Cart}}v_{\text{fx}}$$

(b) Use energy constancy to determine the maximum compression distance:

$$\tfrac{1}{2}m_{\text{You+Cart}}v_{\text{fx}}^2 = \tfrac{1}{2}kA^2$$

(c) Determine the period using

$$T = 2\pi\sqrt{\frac{m_{\text{You+Cart}}}{k}}$$

(d) Use Newton's second law to determine the maximum acceleration during the vibrations after the collision:

$$a_x = \frac{-kx}{m_{\text{You+Cart}}}$$

a is maximum when the spring has its maximum compression (when $x = -A$).

Solve and evaluate (a) The velocity of you and the cart immediately after the collision is

$$v_{\text{fx}} = \frac{m_{\text{You}}v_{\text{You i}\,x} + m_{\text{Cart}}v_{\text{Cart i}\,x}}{m_{\text{You+Cart}}} = \frac{(60\text{ kg})(16\text{ m/s}) + 0}{(60\text{ kg} + 20\text{ kg})}$$
$$= 12\text{ m/s}$$

The speed seems reasonable, and the sign matches the original direction of motion.

(b) Using the equation $\frac{1}{2}m_{\text{You+Cart}}\,v_{\text{f}}^2 = \frac{1}{2}k\,A^2$, we can cancel the $(1/2)$, divide both sides of the equation by k, and take the square root. We find that the maximum displacement of the cart from its equilibrium position is

$$A = \sqrt{\frac{m_{\text{You+Cart}}}{k}}v_{\text{f}} = \sqrt{\frac{80\text{ kg}}{1280\text{ N/m}}}(12\text{ m/s}) = 3.0\text{ m}$$

The compression seems a little high, but the skier was moving with high speed; the units are fine.

(c) The period for the you + cart vibration is

$$T = 2\pi\sqrt{\frac{m_{\text{You+Cart}}}{k}} = 2\pi\sqrt{\frac{80\text{ kg}}{1280\text{ N/m}}} = 1.6\text{ s}$$

(d) The cart started at its equilibrium position ($x = 0$) and was moving at 12 m/s after you collided with it. This is its maximum speed.

The amplitude of the vibration was 3.0 m. Thus, the maximum acceleration of the you + cart system when at the $x = -A$ position is

$$a_{max} = \frac{-k(-A)}{(m_{You+Cart})} = \frac{(1280\ N/m)(3.0\ m)}{(60\ kg + 20\ kg)} = 48\ m/s^2$$

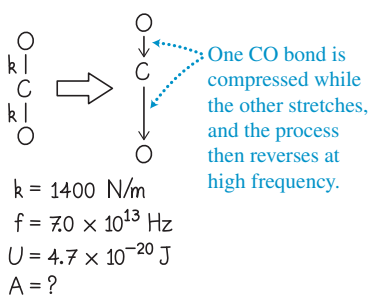
The maximum acceleration of you and the cart is five times free-fall acceleration. The units for the result are the units of acceleration:

$$\frac{(N/m) \times (m)}{(kg)} = \frac{N}{kg} = \frac{kg \times m/s^2}{kg} = m/s^2$$

Try it yourself (a) How would the period of vibration change if you hit the cushion at half the velocity in the example? (b) What would be the period of vibration for a person whose mass is half of yours and whose speed before the collision with the cart is 0.8 times your speed?

Answer (a) The period is independent of the amplitude. (b) The period would be 1.24 s.

Radiation absorption by molecules



We can use what we know about vibrational motion to understand some aspects of global climate change. To maintain a consistent climate, Earth and its atmosphere as a system rely on a balanced exchange of energy in and out of the system. The energy absorbed by the Earth-atmosphere system, which enters the system in the form of visible light and infrared radiation from the Sun, must be balanced by the energy transferred out of that system. The energy is transferred out when vibrating molecules on Earth emit lower frequency infrared radiation that travels away from Earth. The radiation from the Sun is a much higher temperature than that emitted by Earth.

Some of the radiation emitted by molecular vibration on Earth is absorbed by CO_2 molecules in the atmosphere—a form of resonant energy transfer. This absorption causes the vibrational energy of these atmospheric molecules to increase. The excited CO_2 molecules re-emit the infrared radiation, much of which is reabsorbed by molecules on Earth. Thus, less energy is transferred out of the system than is transferred in—the planet warms. This **greenhouse effect** is similar to what happens to a person sitting in a car on a hot summer day. The energy from the Sun in the form of sunlight enters the car and is converted into additional thermal energy of the air in the car. The hot air in the car emits lower frequency infrared radiation, which is absorbed and reflected by the car's windows. Thus, less energy is radiated out of the car—the temperature inside the car rises.

Let's look briefly at the CO_2 vibrations that are involved in this energy absorption.

EXAMPLE 10.9 CO_2 vibration

Within molecules, atoms interact with each other via attractive and repulsive electric forces. These forces maintain a fairly consistent distance between the atoms. When the atoms get close to each other they repel; when they are pulled away they attract. Thus we can model the bond between the atoms as a spring. One of the vibrations in a CO_2 molecule involves an asymmetric stretching and compression of the CO bonds between the carbon and oxygen atoms (see the figure below). This bond has an effective spring constant of 1400 N/m. The vibration of the molecule has a natural frequency of 7.0×10^{13} Hz. (a) Determine the effective mass of the CO_2 molecule when vibrating in this way. (b) When a CO_2 molecule in the atmosphere absorbs infrared energy emitted by Earth, the energy of the vibration is 4.7×10^{-20} J. Estimate the amplitude of the vibration.

Sketch and translate The vibration is depicted in the figure at the bottom of the previous column. We will use the expression for the vibration frequency of a cart with mass m and spring with spring constant k to estimate an effective mass of the vibrating molecule. We can use $\frac{1}{2}kA^2$ for the energy of vibration to estimate the amplitude.

Simplify and diagram Assume that the molecule can be modeled as a system undergoing SHM with a mass m at the end of a spring of spring constant k. We are also assuming that the physics ideas we are using apply to atomic-scale objects (which turns out not to be a very good assumption).

Represent mathematically The frequency of vibration of a mass at the end of a spring is

$$f = \frac{1}{2\pi}\sqrt{\frac{k}{m}}$$

The energy of vibration is

$$U_{total} = \tfrac{1}{2}kA^2$$

(CONTINUED)

Solve and evaluate The effective mass of the vibrating system is

$$m = \frac{k}{4\pi^2 f^2} = \frac{(1400\ \text{N/m})}{4\pi^2(7.0 \times 10^{13}\ \text{s}^{-1})^2} = 7.2 \times 10^{-27}\ \text{kg}$$

The amplitude of vibration is

$$A = \sqrt{\frac{2U_{\text{total}}}{k}} = \sqrt{\frac{2(4.7 \times 10^{-20}\ \text{J})}{1400\ \text{N/m}}} = 8.2 \times 10^{-12}\ \text{m}$$

Are these numbers reasonable? The mass 7.2×10^{-27} kg is approximately the mass of an oxygen atom. The amplitude is a few percent of the typical distance between atoms in a molecule. Both answers thus seem reasonable.

Try it yourself Check the expressions used for each answer to see if they have the correct units.

Answer

$m = \frac{k}{4\pi^2 f^2}$ has units $\frac{(\text{N/m})}{(\text{s}^{-1})^2} = \left(\frac{\text{kg} \cdot \text{m}}{\text{s}^2}\right)\left(\frac{1}{\text{m}}\right)\left(\frac{1}{\text{s}^{-2}}\right) = \text{kg}$,

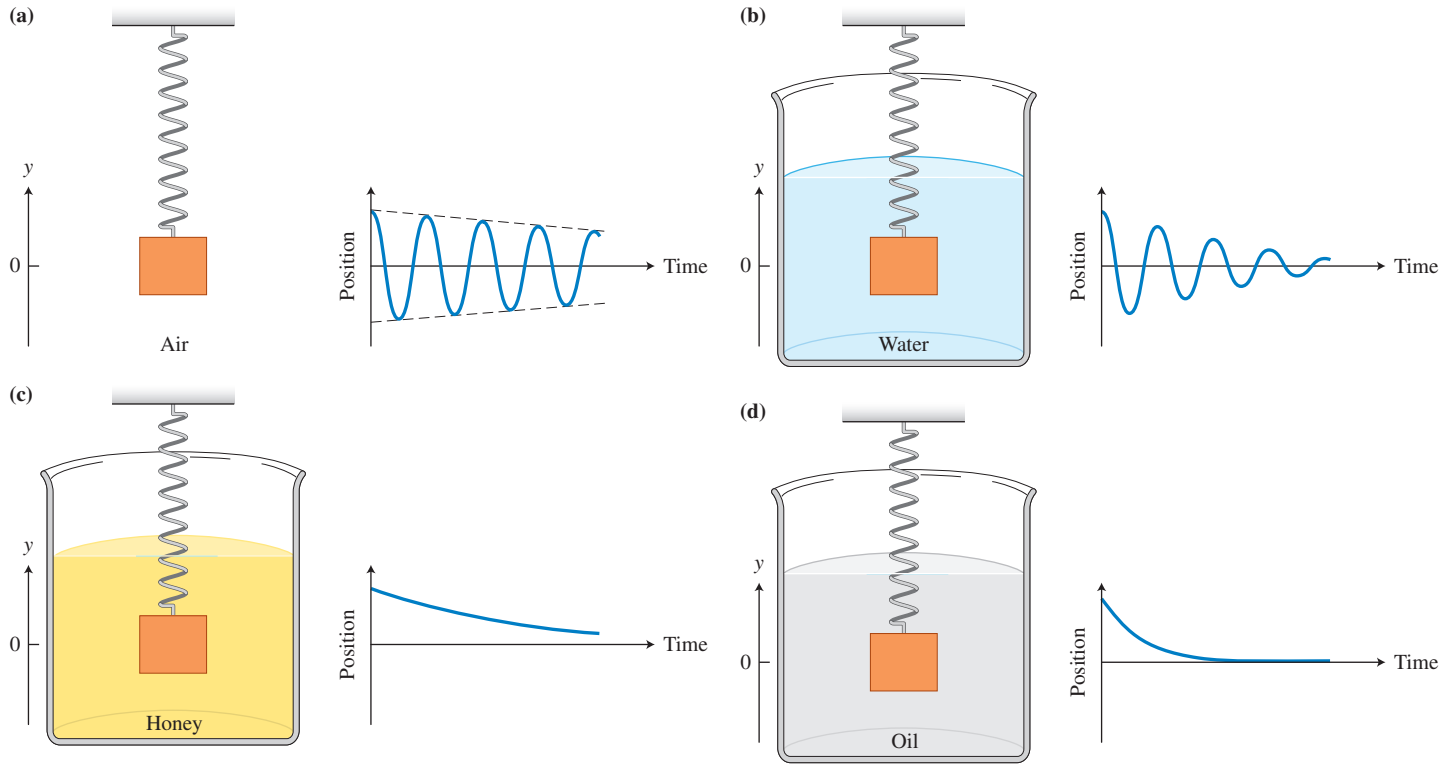
the correct unit for mass. $A = \sqrt{\frac{2U_{\text{total}}}{k}}$ has units

$\sqrt{\frac{\text{J}}{\text{N/m}}} = \sqrt{\frac{\text{N} \cdot \text{m}}{1} \cdot \frac{\text{m}}{\text{N}}} = (\text{m}^2)^{1/2} = \text{m}$, the correct unit for amplitude.

REVIEW QUESTION 10.6 Why was it important to assume that the springs obey Hooke's law in Examples 10.7 and 10.8?

10.7 Including friction in vibrational motion

In the preceding sections, we have mostly ignored the effect of friction on vibrating objects. Without it, though, a car would continue vibrating on its suspension system for miles after crossing a bump on a road, and tall buildings would continue to sway even after the wind had died down.



You can observe the effects of friction on a simple system. Imagine that you have three identical containers, one filled with water, the second with honey, and the third with oil. You also have four identical springs and four identical blocks to hang on those springs. Hang the first block in air, the second in the water, the third in the honey, and the fourth one in the oil (**Figure 10.12**).

Set all four blocks in motion by pulling each one down and releasing it. The position-versus-time graphs in the figure show the motion of the blocks. The block in the air continues to vibrate with almost constant period and with very slowly reducing amplitude. The block in the water makes several vibrations with significantly decreasing amplitude before stopping. (Its frequency also slightly decreases, but this is difficult to observe.) The block in the honey does not even complete one full vibration; it returns to the equilibrium position after a very long time. The block in the oil quickly returns to the equilibrium position, but does not go past it. This phenomenon of decreasing vibration amplitude and increasing period is called **damping**. In practice, all vibrational systems are subject to some damping.

When we discuss vibrations with damping, vibrational systems are called *oscillators*. If the oscillator oscillates with decreasing amplitude, it is referred to as *underdamped* (the block in water and, to a lesser degree, the block in air). The damping of underdamped oscillators can vary to some degree (smaller or larger damping) as long as the system passes the equilibrium positions several times. If the displacement of the oscillator is smoothly (asymptotically) approaching the equilibrium position (without oscillations), it is referred to as *overdamped* (the block in honey and some door mechanisms). For a particular degree of damping, the oscillator reaches the equilibrium position in the shortest time and remains there. This case is referred to as *critical damping* (the block in oil). Critical damping has several important applications in industry and engineering (for example, in robots' arms that have to be designed to reach the target objects in the shortest time).

Damping is a useful aspect in the design of vehicles and bridges. For example, a mountain bike has shock absorbers to decrease the force exerted by the surface on the

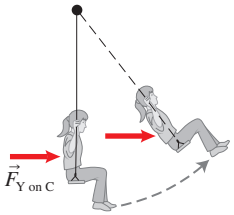
FIGURE 10.12 Differently damped oscillators. (a) An underdamped oscillator (small damping); (b) an underdamped oscillator (larger damping); (c) an overdamped oscillator; (d) a critically damped oscillator.

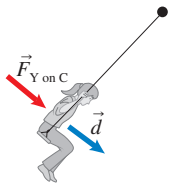
front tire when the tire hits a bump or a hole in the trail. The shock absorbers consist of springs and oil-filled dampers in the front fork of the bicycle and underneath the seat. The spring is wrapped around a piston filled with oil (**Figure 10.13**). During a collision, the spring compresses and increases the stopping distance, thus smoothing the effect of the collision on the rider. When the spring compresses, the piston pushes oil through a small hole. This process converts the spring's elastic potential energy into internal energy in the oil. Instead of continuing to bounce up and down, the spring returns quickly to its noncompressed position.

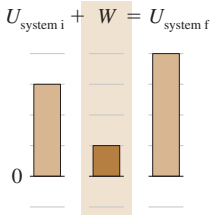
Damping is not desirable in all cases. Spiders that spin webs depend on vibrations to locate and restrain prey. An insect striking the web will produce vibrations that allow the spider to locate the insect. The farther these vibrations travel before damping out, the more likely it is that the spider will locate its prey (**Figure 10.14**).

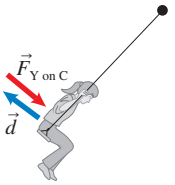
FIGURE 10.13 A shock absorber for a mountain bike.

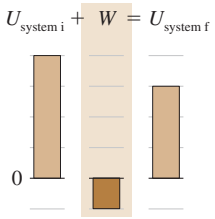
FIGURE 10.14 Vibrations in the spiderweb help the spider locate the captured prey.











REVIEW QUESTION 10.7 What features of damped vibrational motion make it different from SHM?

10.8 Vibrational motion with an external driving force

All real vibrations are damped and eventually stop unless energy is added to the system to compensate. In Observational Experiment **Table 10.6** (on the next page), we investigate how external interactions of the environment with a vibrating system could lead to continuous vibrations.

OBSERVATIONAL EXPERIMENT TABLE 10.6 A forced vibration

VIDEO OET 10.6

Observational experiment	Analysis
Experiment 1. A young child sits on a swing. You exert a steady force on the child and swing until the swing cable is at such an angle that the swing stops (this angle depends on the construction of the swing). There are no vibrations. 	The swing, child, and Earth are the system (but not you). You exerted a constant force that did positive work on the swing. But no vibrations occurred during this time.
Experiment 2. A young child swings with a period $T = 2\pi\sqrt{L/g}$. You push her gently and briefly every time just after she reaches the peak of her vibration. Each brief push is in the same direction as her displacement. The pushes have the same period as her swinging. 	You exerted a variable force that did positive work on the swing. The energy of the system increased. The amplitude of the swing vibrations increases. 
Experiment 3. The child still swings with period $T = 2\pi\sqrt{L/g}$. This time, you push her gently and briefly as she swings back toward you, just before she reaches the peak of her vibration. You push opposite the direction of her displacement. 	You did negative work on the swing. The energy of the system decreased. The amplitude of the swing vibrations decreases. 
Experiment 4. The child still swings with period $T = 2\pi\sqrt{L/g}$. This time, you push her gently with a different period. Sometimes you push as she is moving back and at other times as she is moving forward. Her amplitude becomes small and stays small.	You do positive work sometimes and negative work at other times (the net work over time is zero). Friction and air resistance cause the swinging amplitude to decrease.

Patterns

For an external force exerted on the swinging system to cause the amplitude to increase:

1. The external force has to be a *variable force*.
2. The external force must do *positive work* on the vibrating system.
3. The *period (and therefore frequency)* of the external force *must match* that of the vibrating system.

To test these patterns, we use them to predict the results of the following experiment. A string is tied between two ring stands—the string sags a little (**Figure 10.15a**). Six pendulums of different lengths are attached to the string (80 cm, 10 cm, 50 cm, 80 cm, 100 cm, and 120 cm). What happens if we pull the 80-cm-long pendulum on the left in the direction perpendicular to the orientation of the string and let it go?

The swinging 80-cm-long pendulum causes the horizontal string to move back and forth at the **natural frequency** of the 80-cm-long pendulum:

$$f_0 = \frac{1}{2\pi}\sqrt{\frac{9.8\ \text{m/s}^2}{0.80\ \text{m}}} = 0.56\ \text{s}^{-1} = 0.56\ \text{Hz}$$

This 0.56-Hz motion of the vertical string causes it to pull the horizontal string back and forth at that frequency, which in turn tugs on the other vertical strings and thus does work on the other five pendulums. All pendulums start swinging at the 0.56-Hz frequency. However, since only the other 80-cm pendulum has the same natural frequency, we predict that only that pendulum will eventually swing with large amplitude. This is what we observe, a phenomenon called **resonance**—the increase in the amplitude of vibration of one of the pendulums while all other pendulums vibrate with smaller amplitudes. Resonance occurs in vibrating systems when some object in the environment exerts a force on it that varies in time and does net positive work over

time. This work leads to an increase in the total energy of the system and therefore to the increase of the amplitude of vibration. This increase in energy occurs when the frequency of the external force is either the same as the natural frequency of the system without damping or close to the natural frequency for the systems with damping. The child on the swing exhibited another example of resonance, when the frequency of the variable force exerted on her was close to the natural frequency of the swing.

As we continue to observe the pendulums, an even more unusual thing happens. As time passes, the amplitude of the original 80-cm pendulum decreases to zero as the amplitude of the second 80-cm pendulum reaches a maximum. Then the first pendulum begins vibrating again as the second pendulum's amplitude decreases. Energy is being gradually transferred from one 80-cm-long pendulum to the other. This is an example of **resonant energy transfer**.

Finally, it is important to notice that the amplitudes of vibration of the other pendulums are not the same. The closer the length of the pendulum is to 80 cm, the larger the amplitude of vibration of that pendulum (see Figure 10.15b). This pattern can be generalized for any oscillator driven by a variable force. The closer the frequency of the external force to the natural frequency of the oscillator, the greater the amplitude.

We can see an example of energy transfer through resonance in our chapter-opening story about the Russian soldiers marching across a bridge. When the frequency of their steps approached the natural vibration frequency of the bridge, the marching initiated large-amplitude vibrations in the bridge, which led to its collapse. Any small vibrations that the bridge had were amplified by the positive work done by the soldiers on the bridge. As the amplitude of the vibrations increased, parts of the bridge twisted and pulled apart, and eventually the bridge collapsed.

Resonance caused the collapse of the Tacoma Narrows Bridge in Washington only four months after its completion. Unbeknownst to the engineers who designed it, vibrations near one of the bridge's resonant frequencies would increase in amplitude rather than damp out. On November 7, 1940, a strong wind combined with the bridge's natural twisting vibration caused an amplitude vibration of over 3 m at the sides of the bridge (**Figure 10.16a**). It collapsed after about an hour (Figure 10.16b).

Vocalists have been known to break wine glasses by producing sounds of particular frequencies. To do so, they must match the natural frequency of the wine glass (about 560 Hz). You are probably familiar with another example of energy transfer through resonance: spilling a beverage while carrying it across a room.

CONCEPTUAL EXERCISE 10.10 **Carrying a glass of juice**

Snehal is crossing a room while carrying a glass of cranberry juice. Estimate the stepping frequency that might cause the juice to splash onto the carpet. The natural frequency of vibrations of the juice sloshing in the nearly full glass is about 3 vibrations/s.

Sketch and translate Snehal's arm is a vibrating object that interacts with the glass of juice as well as with his legs.

Simplify and diagram Assume that Snehal's hand and arm oscillate at the same frequency at which his feet hit the ground. To avoid spilling the cranberry juice, he should try to walk so that his feet do not hit the ground 3 times per second (or 1.5 steps/s for each foot). That is a rapid pace, so it is unlikely that Snehal will cause resonant vibrations in the glass.

Try it yourself Do a follow-up investigation. First, determine the natural sloshing frequency in some container of liquid. Then walk with each of your legs swinging at the same frequency to see if the liquid spills. Think about what other factors affect the possibility of a coupled resonance between your stepping and the sloshing vibrations of liquid in a container. List the possible factors and then do experiments to determine the effect of changing those factors.

REVIEW QUESTION 10.8 Describe the phenomenon of energy transfer by resonance and explain why it happens.

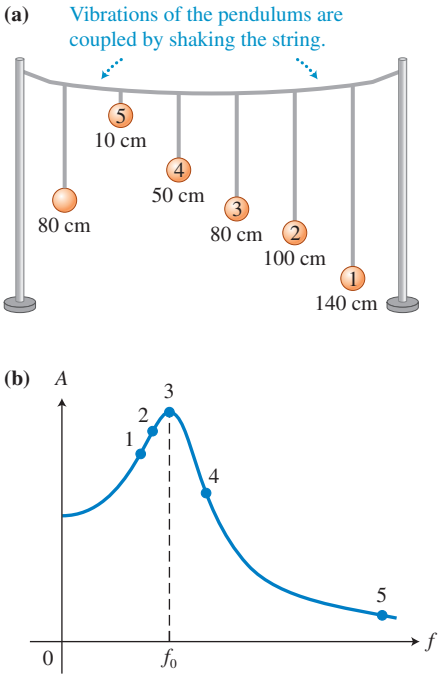

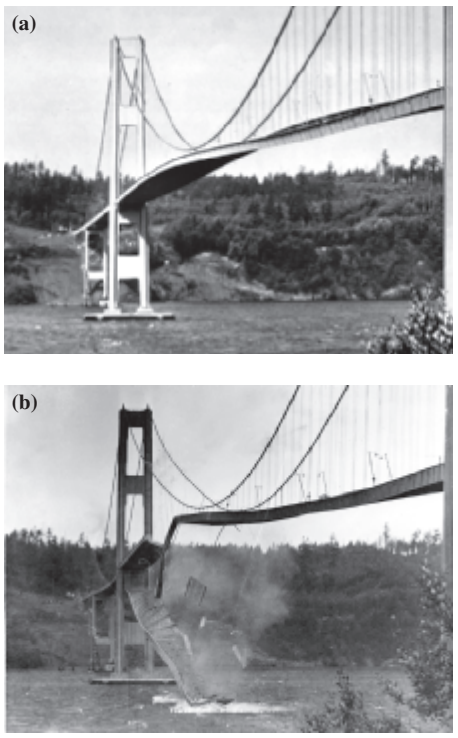

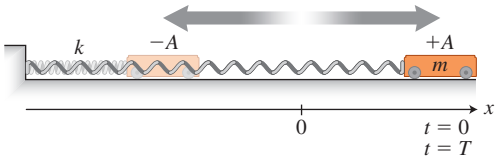

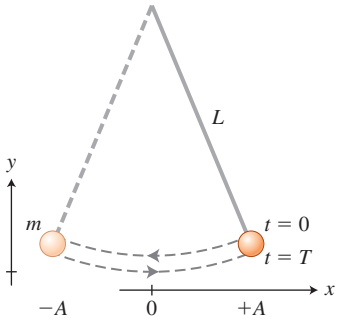

FIGURE 10.16 The collapse of the Tacoma Narrows bridge.

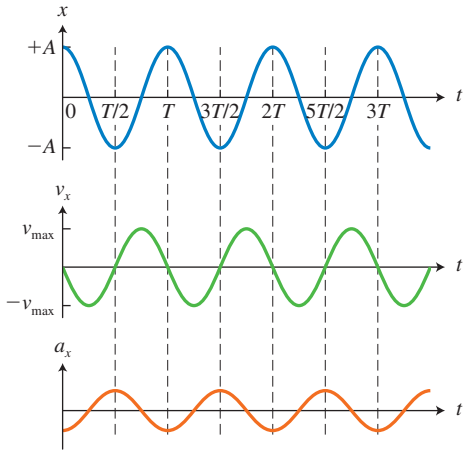
Summary

Vibrational motion is the repetitive movement of an object back and forth about an **equilibrium position**. This vibration is due to the **restoring force** exerted by another object that tends to return the first object to its equilibrium position. An object's maximum displacement from equilibrium is the **amplitude** A of the vibration. **Period** T is the time interval for one complete vibration, and **frequency** f is the number of complete vibrations per second (in hertz). The frequency is the inverse of the period. (Section 10.1)

Object at end of spring obeying Hooke's law:

$$F_{\text{Restoring } x} = -kx \qquad \text{Eq. (10.5)}$$



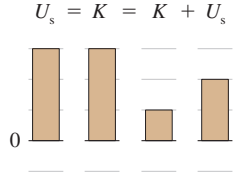
$$T = 2\pi\sqrt{\frac{m}{k}} = \frac{1}{f} \qquad \text{Eq. (10.7)}$$

Simple pendulum:

$$F_{\text{Restoring } x} = -\left(\frac{mg}{L}\right)x \qquad \text{Eq. (10.11)}$$

$$T = 2\pi\sqrt{\frac{L}{g}} = \frac{1}{f} \qquad \text{Eq. (10.12)}$$

Simple harmonic motion is a mathematical model of vibrational motion when position x, velocity v, and acceleration a of the vibrating object change as sine or cosine functions with time. (Section 10.2)



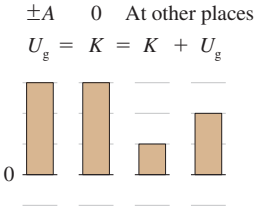
$$x = A\cos\left(\frac{2\pi}{T}t\right) \qquad \text{Eq. (10.2)}$$

$$v_x = -\left(\frac{2\pi}{T}\right)A\sin\left(\frac{2\pi}{T}t\right) \qquad \text{Eq. (10.3)}$$

$$a_x = -\left(\frac{2\pi}{T}\right)^2 A\cos\left(\frac{2\pi}{T}t\right) \qquad \text{Eq. (10.4)}$$

The **energy of a spring-object system** vibrating horizontally converts continuously from elastic potential energy when at the extreme positions to maximum kinetic energy when passing through the equilibrium position to a combination of energy types at other positions. (Section 10.3)

Object at end of spring:



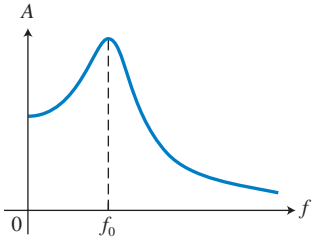
$$E = \tfrac{1}{2}kx^2 + \tfrac{1}{2}mv^2$$

$$E = \tfrac{1}{2}kA^2$$

$$= \tfrac{1}{2}mv_{\text{max}}^2 \qquad \text{Eq. (10.9)}$$

The **energy of a pendulum-Earth system** converts continuously from gravitational potential energy when it is at the maximum height of a swing to kinetic energy when it is passing through the lowest point in the swing to a combination of energy types at other positions. (Section 10.5)

Simple pendulum:

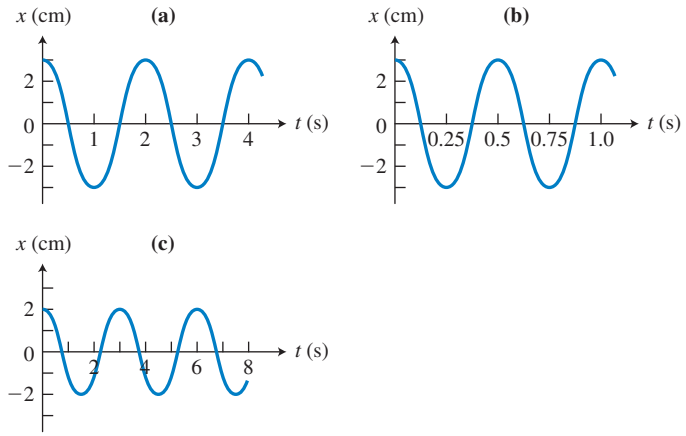


$$E = mgy + \tfrac{1}{2}mv^2$$

$$E = mgy_{\text{max}}$$

$$= \tfrac{1}{2}mv_{\text{max}}^2$$

Resonant energy transfer occurs when the frequency of the variable external force driving the oscillations is close to the **natural frequency** f_0 of the vibrating system. (Section 10.8)



Questions

Multiple Choice Questions

1. What are the features that make vibrational motion *different* from circular motion? Choose all that apply.
   (a) Vibrational motion is periodic.
   (b) Vibrational motion repeats itself.
   (c) During vibrational motion, there is a periodic change in the form of system energy.
   (d) Vibrational motion has a specific equilibrium point through which the system passes from different directions.
2. What does it mean if the amplitude of an object's vibration is constant and equal to 0.10 m?
   (a) The object's maximum distance from the starting point is 0.10 m.
   (b) The object's displacement from the equilibrium position is ± 0.10 m.
   (c) The magnitude of the object's maximum displacement from the equilibrium position is 0.10 m.
3. What does it mean if the period of an object's vibration equals 0.60 s?
   (a) The motion lasts for 0.60 s.
   (b) The time interval needed for the object to move between the two farthest points from the equilibrium position is 0.60 s.
   (c) The time interval needed for the object to move through the same point in the same direction is 0.60 s.
4. What is the period of the kinetic or the potential energy change if the period of position change of an object attached to a spring is 2.0 s?
   (a) The energy does not change. (b) 4.0 s
   (c) 2.0 s (d) 1.0 s
5. A cart undergoing simple harmonic motion has a 2.0-Hz frequency and 3.0-cm amplitude. At time zero, the cart is at $x = +A$. Which of the three position-versus-time graphs shown in **Figure Q10.5** best represents the motion?

FIGURE Q10.5

6. The period of the object attached to a spring is T. How much time does the object need to move from the equilibrium position to half the amplitude?
   (a) $T/2$ (b) $T/6$
   (c) $T/8$ (d) $T/12$
   (e) There are not enough data to answer.
7. You have a simple harmonic oscillator. Where is its acceleration zero?
   (a) At the equilibrium position
   (b) At the maximum distances from equilibrium
   (c) At $t = 0$
   (d) Because the oscillator is constantly moving, there is no place where its acceleration is zero.
8. You have a simple harmonic oscillator. Where is the magnitude of its acceleration at its maximum?
   (a) At the equilibrium position
   (b) At the maximum distances from equilibrium
   (c) At $t = 0$
   (d) The acceleration is constant.
9. Which of the following arguments can be used to support the statement that an object attached to a light spring undergoes simple harmonic motion after it is displaced from the equilibrium position?
   (a) Because the position-versus-time graph is a sinusoidal-type function
   (b) Because the acceleration of the object is proportional to its displacement with a negative sign
   (c) Because the motion is periodic and has a constant period
   (d) Because the speed of the object is largest when it passes the equilibrium position.

Conceptual Questions

10. (a) Give three common examples of vibrational motion with damping. Explain the reasons for the damping. (b) Give a common example of a forced vibration. (c) Give a common example of resonance. Do not use any examples already used in this chapter.
11. An object of known mass hangs at the end of a spring, causing it to stretch a distance ΔL. How can you determine the frequency of vibration of this object if you know only the mass and the stretching distance?
12. Describe two different ways to estimate the spring constant of a rubber band using only a 100-g object, a stopwatch, and a meter stick. Describe the assumptions that you need to make in each estimate.
13. You have a small metal ball attached to a 1.0-m string. Explain two different methods that you can use with this apparatus to measure free-fall acceleration at this location.
14. A pendulum clock is running too fast. Explain how you can fix the problem.
15. What simplifications were used to derive the formula for the period of vibration of an object at the end of a spring and of a simple pendulum?
16. A pendulum clock is moved from the Mississippi Delta region to the Rocky Mountains. Will the clock run faster or slower in the Rockies? Why? How can it be adjusted to compensate for this change? Describe your assumptions.
17. Oil is often found in a geological structure called a salt dome. The rock in the salt dome is less dense than surrounding rock and is pushed up so that it "floats" on surrounding rock. Explain how a sensitive pendulum can detect a salt dome.
18. By experiment and by calculation, estimate the natural period and frequency of vibration of your arm. Carefully explain the values of the numbers used in each estimate.
19. A pendulum and a block hanging at the end of a spring are both carefully adjusted to make one vibration each second when on Earth's surface. Will the period of vibration of the pendulum or of the block on the spring be affected if they are placed on the Moon? Explain.
20. Will the frequency of vibration of a swing when you stand on the swing be greater or less than when you sit? Explain.
21. Estimate the time interval required for a Chihuahua to take a single step. Estimate the time interval required for a giraffe to take a single step.
22. The amplitude of vibration of a swing slowly decreases to zero if you do not pump your legs while swinging. Explain what happens to the energy of the system.
23. If you walk with your arms hanging down, they often oscillate forward and back at the same frequency as your stepping frequency. However, if your arms are bent at the elbow so that the forearms are horizontal, they often do not oscillate. Why?
24. You have a pendulum with a 1-m string. What is the period of vibration of the pendulum when it is placed on a spaceship orbiting Earth? Explain.

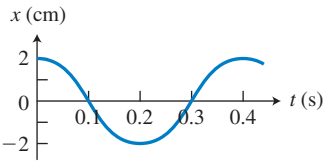
Problems

Below, BIO indicates a problem with a biological or medical focus. Problems labeled EST ask you to estimate the answer to a quantitative problem rather than derive a specific answer. Asterisks indicate the level of difficulty of the problem. Problems with no * are considered to be the least difficult. A single * marks moderately difficult problems. Two ** indicate more difficult problems.

10.1 Observations of vibrational motion

1. A low-friction cart is placed between two identical springs that are attached to rigid walls, as shown in **Figure P10.1**. If you push the cart against one spring and release it, it continues moving back and forth between the springs. Is this simple harmonic motion? Explain why or why not. Compare this case with the case where the cart is attached to the spring (such as the cart in Figure 10.8). Describe similarities and differences.

FIGURE P10.1

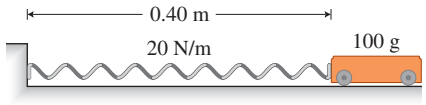


2. * You have a ball bearing and a bowl. You let the ball roll down from the top of the bowl; it moves up and down the bowl's wall for some time. (a) Is this vibrational motion? Explain why or why not. (b) Draw a force diagram for the ball for four different positions and indicate what force or force component is responsible for the acceleration toward the equilibrium position. (c) Draw energy bar charts for these four ball-Earth system positions.
3. Draw a sketch of a pendulum. Indicate the equilibrium position. Show this object vibrating and indicate the amplitude of vibration on the sketch.
4. * (a) Draw a sketch of an object attached to a vertical spring. Indicate the equilibrium position. (b) Show this object vibrating up and down and indicate the amplitude of vibration on the sketch. (c) Describe an experiment you would perform to determine the period of vibration of the object. (d) Perform the experiment. Include experimental uncertainty in your result.

10.2 Kinematics of vibrational motion

5. Draw a graph showing the position-versus-time curve for a simple harmonic oscillator (a) with twice the frequency of that shown in **Figure P10.5** and (b) with the same frequency but twice the amplitude as shown in the figure.

FIGURE P10.5



6. Suppose that at time zero the cart attached to the spring such as shown in Figure 10.8 is released from rest at position $x = +A$ and that its period of vibration is 8.0 s. Draw nine sketches showing the cart's approximate position each second starting at 0 s and ending at 8.0 s. Draw and label arrows indicating the relative velocity and acceleration of the cart at each position.
7. * (a) Sketch a motion diagram and a position-versus-time graph for the motion of a cart attached to a spring during one period. It passes at high speed through the equilibrium position at time zero. (b) Sketch a velocity-versus-time graph for the cart. (c) Sketch an acceleration-versus-time graph for the cart. (d) Draw another representation of the process; explain how this representation allows you to learn more about the process than the kinematics graphs do.
8. * Devise a position-versus-time function that describes the simple harmonic motion of an object of your choice. Choose the amplitude and the period of vibration, and draw corresponding velocity-versus-time and acceleration-versus time graphs. Draw a motion diagram for one period of its motion.
9. * The position of a vibrating object changes as a function of time as $x = (0.2\text{ m})\cos[(\pi\text{ s}^{-1})t]$. Say everything you can about this motion. Write expressions for the velocity and acceleration as functions of time. Draw graphs for each function.
10. * The velocity of a vibrating object changes as a function of time as $v = -(0.6\text{ m/s})\cos[(2\pi\text{ s}^{-1})t]$. (a) Say everything you can about the motion. Draw a sketch of the situation when the motion starts. (b) Represent the motion with a position-versus-time graph and a work-energy bar chart.
11. * A cart at the end of a spring undergoes simple harmonic motion of amplitude 10 cm and frequency 5.0 Hz. (a) Determine the period of vibration. (b) Write an expression for the cart's position at different times, assuming it is at $x = -A$ when $t = 0$. Determine its position (c) at 0.050 s and (d) at 0.100 s.
12. ** Refer to the situation in Problem 10.1. (a) Draw position-versus-time and velocity-versus-time graphs for two cycles of the motion of the cart. (b) Derive the expression for the period of the motion of the cart as a function of relevant parameters.

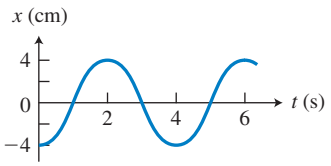
10.3 Dynamics of simple harmonic motion

13. You exert a 100-N pull on the end of a spring. When you increase the force by 20% to 120 N, the spring's length increases 5.0 cm beyond its original stretched position. What is the spring constant of the spring and its original displacement?
14. **Metronome** You want to make a metronome for music practice. You use a 30-g object attached to a spring to serve as the time standard. What is the desired spring constant of the spring if the object needs to make 1.00 vibrations each second? What are the assumptions that you made?
15. Determine the frequency of vibration of the cart shown in **Figure P10.15**.

FIGURE P10.15

16. * A spring with a cart at its end vibrates at frequency 6.0 Hz. (a) Determine the period of vibration. (b) Determine the frequency if the cart's mass is doubled while the spring constant remains unchanged and (c) the frequency if the spring constant doubles while the cart's mass remains the same.
17. A cart with mass m vibrating at the end of a spring has an extra block added to it when its displacement is $x = +A$. What should the block's mass be in order to reduce the frequency to half its initial value?
18. * A 300-g apple is placed on a horizontal platform that can vibrate in the vertical direction with a fixed amplitude of 1.0 cm. What is the maximum frequency of the platform's vibration for the apple to remain in contact with the platform? (Hint: Think about how the platform needs to move to lose contact with the apple.)
19. ** A 2.0-kg cart vibrates at the end of an 18-N/m spring with the amplitude of 3.0 cm. (a) Make a list of physical quantities you can determine about the vibrations and determine two of them. (b) If a second 18-N/m spring is attached beside the first one, what will be the period of the vibration?
20. * What were the main ideas that we used to derive the expression for the period of an object vibrating at the end of a spring? Explain the assumptions that we made. When is the expression for the period not valid for a spring of known k?

10.4 Energy of vibrational systems



21. * A spring with a spring constant of 1200 N/m has a 55-g ball at its end. (a) If the energy of the system is 6.0 J, what is the amplitude of vibration? (b) What is the maximum speed of the ball? (c) What is the speed when the ball is at a position $x = +A/2$? What assumptions did you make to solve the problem? How do you know if your answer makes sense?
22. * A person exerts a 15-N force on a cart attached to a spring and holds the cart steady. The cart is displaced 0.060 m from its equilibrium position. When the person stops holding the cart, the system cart+spring undergoes simple harmonic motion. (a) Determine the spring constant of the spring. (b) Determine the energy of the system. (c) Write an expression $x(t)$ for the motion of the cart. (d) Draw as many graphical representations of the motion as you can.

23. A spring with spring constant 2.5×10^4 N/m has a 1.4-kg cart at its end. (a) If its amplitude of vibration is 0.030 m, what is the total energy of the cart+spring system? (b) What is the maximum speed of the cart? (c) If the energy is tripled, what is the new amplitude? (d) What is the new maximum speed of the cart? (e) What assumptions did you make to solve the problem? If the assumptions were not reasonable, how would the answers change?
24. * **Proportional reasoning** By what factor must we increase the amplitude of vibration of an object at the end of a spring in order to double its maximum speed during a vibration? Explain.
25. **Proportional reasoning** By what factor must we increase the amplitude of vibration of an object at the end of a spring in order to double the total energy of the system? Explain. What will happen to the speed of the object? What assumptions did you make?
26. **Monkey trick at zoo** A monkey has a cart with a horizontal spring attached to it that she uses for different tricks. In one trick, the monkey sits on the vibrating cart. When the cart reaches its maximum displacement from equilibrium, the monkey picks up a 0.30-kg cantaloupe from a trainer. The mass of the monkey and the cart together is 3.0 kg. The spring constant is 660 N/m. The amplitude of horizontal vibrations is 0.24 m. Determine the ratio of the maximum speed of the monkey before and after she picks up the cantaloupe.
27. * A frictionless cart attached to a spring vibrates with amplitude A. (a) What fraction of the total energy of the cart-spring system is elastic potential energy and what fraction is kinetic energy when the cart is at position $x = A/2$? (b) At what position is the cart when its kinetic energy equals its elastic potential energy?
28. A 2.0-kg cart attached to a spring undergoes simple harmonic motion so that its displacement is described by $x = (0.20\text{ m})\sin[(2\pi/2.0\text{ s})t]$. Construct energy bar charts for the cart-spring system at times $t = 0$, $t = T/4$, $t = T/2$, $t = 3T/4$, and $t = T$.
29. * The motion of a cart attached to a horizontal spring is described as $x = (0.17\text{ m})\sin(\pi s^{-1})t$. Say everything you can about this motion and represent it using graphs, motion diagrams, and energy bar charts.

10.5 The simple pendulum

30. **Pendulum clock** Shawn wants to build a clock whose pendulum makes one swing back and forth each second. (a) What is the desired length of the rod (assumed to have negligible mass) holding the metal ball at its end? (b) Will the rod need to be shorter or longer if he includes the mass of the rod in the calculations? Explain.
31. Show that the expression for the frequency of a pendulum as a function of its length is dimensionally correct.
32. A pendulum swings with amplitude 0.020 m and period of 2.0 s. What is its maximum speed?
33. * **Proportional reasoning** You are designing a pendulum clock whose period can be adjusted by 10% by changing the length of the pendulum. By what percent must you be able to change the length to provide this flexibility in the period? Explain.
34. * **Building demolition** A 500-kg ball at the end of a 30-m cable suspended from a crane is used to demolish an old building. If the ball has an initial angular displacement of 15° from the vertical, determine its speed at the bottom of the arc.
35. * You have a pendulum with a long string whose length you can vary but cannot measure, a small ball, and a stopwatch. Describe two experiments that you can design to determine the height of a ladder. Indicate the assumptions that you use in each method.
36. * **Variations in g** The frequency of a person's pendulum is 0.3204 Hz when at a location where g is known to be exactly 9.800 m/s^2. Where might the same pendulum be when its frequency is 0.3196 Hz? What is g at that location?
37. EST A graph of position versus time for an object undergoing simple harmonic motion is shown in Figure P10.37. Estimate from the graph the amplitude and period of the motion and determine the object's frequency. If the object is a pendulum, what is its length?

FIGURE P10.37

38. Determine the period of a 1.3-m-long pendulum on the Moon where the free-fall acceleration is 1.624 m/s^2.
39. * You have a simple pendulum that consists of a small metal ball attached to a long string. You push the ball so that at time $t = 0$ it moves with a speed of 2 m/s through the equilibrium position in the positive x-direction and continues oscillating with the amplitude of 20 cm. (a) Draw labeled position-versus-time and velocity-versus-time graphs for the first two periods of oscillation. (b) Determine the length of the string.

10.6 Skills for analyzing processes involving vibrational motion

40. * **Equation Jeopardy** The following expression describes a situation involving vibrational motion. Sketch a process and devise a problem for which the expression might be an answer.

$$\tfrac{1}{2}(20{,}000\text{ N/m})(0.20\text{ m})^2 = \tfrac{1}{2}(100\text{ kg})v^2 + \tfrac{1}{2}(20{,}000\text{ N/m})(0.10\text{ m})^2$$

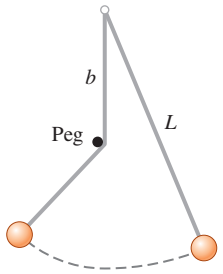
41. * **Trampoline vibration** When a 60-kg boy sits at rest on a trampoline, it sags 0.10 m at the center. (a) What is the effective spring constant for the trampoline? (b) The trampoline is pulled downward an extra 0.050 m by a strap sewed under the center of the trampoline. When the strap is released, what are the energy and frequency of the boy-trampoline system? What assumptions did you make?
42. * **Proportional reasoning** If you double the amplitude of vibration of an object at the end of a spring, how does this affect the values of k, T, U, and v_{max}?
43. * **Pendulum on Mars** The frequency of a pendulum is 39% less when on Mars than when on Earth's surface. Use this fact to determine Mars's gravitational constant.
44. * BIO EST **Annoying sound** Low-frequency vibrations (less than 5 Hz) produced by a certain buzzer are annoying for humans near the buzzer if the product of the buzzer's amplitude and frequency squared (Af^2) exceeds the value $0.5 \times 10^{-2}\text{ m}\cdot\text{s}^{-2}$. Estimate the smallest frequency and amplitude of a buzzer that produces these annoying vibrations if the device vibrates a total mass of 0.12 kg and has a vibrational energy of 5.0×10^{-4} J.
45. ** A 1.2-kg block sliding at 6.0 m/s on a frictionless surface runs into and sticks to a spring. The spring is compressed 0.10 m before stopping the block and starting its motion back in the opposite direction. What can you determine about the vibrations that start after the collision? Make a list of physical quantities and determine four of them.
46. ** EST **Willis Tower vibration** The mass of the Willis (formerly Sears) Tower in Chicago is about 2×10^8 kg. The tower sways back and forth at a frequency of about 0.10 Hz. (a) Estimate the effective spring constant for this swaying motion. Explain why you included a particular number of significant figures. (b) A gust of wind hitting the building exerts a force of about 4×10^6 N. By approximately how much is the top of the building displaced by the wind? Explain why you included a particular number of significant figures. State the assumptions that you made. Does your answer make sense?
47. ** You shoot a 0.050-kg arrow into a 0.50-kg wooden cart that sits on a horizontal, frictionless surface at the end of a spring that is attached to the wall at the other end. The arrow hits the cart and sticks into it. The cart and arrow together compress the spring and start the system vibrating at a frequency of 2.0 Hz with a 0.20-m amplitude. How fast was the arrow moving? State any assumptions you made to solve the problem.

10.7 Including friction in vibrational motion

48. * You have a pendulum whose length is 1.3 m and bob mass is 0.20 kg. The amplitude of vibration of the pendulum is 0.07 m. (a) Determine the maximum energy of the bob-Earth system. Explain why you included a particular number of significant figures. (b) How much mechanical energy is converted to internal energy before the pendulum stops?

49. * You hang a 0.10-kg block from a spring, causing the spring to stretch 0.070 m. When the block is hanging at rest at this equilibrium position, you pull it down with a spring scale and let go of the block when the scale reading is 3.0 N. (a) Where was the block when you let go? (b) Determine the work you did stretching the spring. (c) What was the energy of the spring-block-Earth system when you let go? (d) How far will the block rise after you release it? (e) The vibrations last for 50 cycles. Qualitatively represent the beginning of cycle #1 and the beginning of cycle #25 with an energy bar chart.
50. * Imagine that you have a cart on a spring that moves on a horizontal surface with no friction. (a) Represent the cart's motion with a motion diagram for one period. (b) Draw force diagrams for each quarter of a period. (c) Draw energy bar charts for each quarter of a period. (d) Draw position-, velocity-, and acceleration-versus-time graphs for each period. (e) On these graphs, use a dashed line to sketch graphs for the same cart on the same spring, assuming there is a friction force between the cart and the surface.
51. Describe one situation from everyday life in which large damping is desirable and one in which it is not desirable.

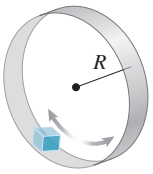
10.8 Vibrational motion with an external driving force



52. EST **Twins on a swing** How frequently do you need to push a swing with twin brothers on it compared to when pushing the swing with one on it? What assumptions did you make?
53. (a) Determine the maximum speed of a girl on a 3.0-m-long swing when the amplitude of vibration is 1.2 m. (b) What assumptions did you make? Is the child's vibrational motion damped? Explain. (c) Under what conditions is the motion a forced vibration? Explain.
54. * **Sloshing water** You carry a bucket with water that has a natural sloshing period of 1.7 s. At what walking speed will water splash if your step is 0.90 m long?
55. * **Feeling road vibrations in a car** If the average distance between bumps on a road is about 10 m and the natural frequency of the suspension system in the car is about 0.90 Hz, at what speed will you feel the bumps the most?
56. * EST A vertical spring oscillator consists of a 0.3-m-long spring and the 30-g metal cube attached to its lower end. The upper end of the spring is attached to a mechanism that vibrates with the adjustable amplitude A_0 and period T. Some students measure how the amplitude of vibration of the lower end of the spring A_S depends on different settings of the mechanism. Their data are shown in the table at right. (a) Estimate the natural frequency of the spring oscillator. (b) Estimate the spring constant of the spring. (c) When the period of vibration of the mechanism is 0.040 s, is the period of vibration of the metal cube less than 0.04 s, larger than 0.04 s, or about 0.04 s?

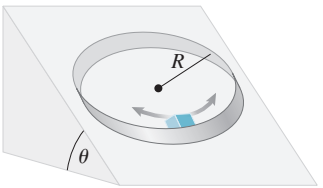
T (s)	A_0	A_S
0.100	1	4.3
0.100	2	8.7
0.100	3	13.0
0.100	4	17.3
0.200	1	3.0
0.067	1	6.7
0.050	1	2.8
0.040	1	1.4

General Problems



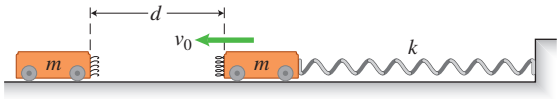
57. A spring oscillator and a simple pendulum have equal natural frequencies on Earth. Determine the ratio of their periods $T_{\text{Spr Osc}}/T_{\text{Sim Pen}}$ on the Moon.
58. * You attach a block (mass m) to a spring (spring constant k) that oscillates in a vertical direction. Determine an expression for the period of its vibrations. Sketch a position-versus-time graph for the vibrations, assuming that the motion starts when the block is at its lowest maximum displacement from the equilibrium position. What assumptions did you make?
59. * You attach a 1.6-kg object to a spring, pull it down 0.12 m from the equilibrium position, and let it vibrate. You find that it takes 5.0 s for the object to complete 10 vibrations. Make a list of physical quantities that you can determine about the motion of the object and determine five of them.
60. * **Traveling through Earth** A hole is drilled through the center of Earth. The gravitational force exerted by Earth on an object of mass m as it goes through the hole is $mg(r/R)$, where r is the distance of the object from Earth's center and R is the radius of Earth $(6.4 \times 10^6\ \text{m})$. Will an object dropped into the hole execute simple harmonic motion? If yes, find the period of the motion. Would this be a comfortable ride? How does one-half of this time compare with the time needed to fly in an airplane halfway around Earth? What assumptions did you make to solve the problem?
61. * EST Estimate the effective spring constant of the suspension system of a car. Describe your technique carefully. How can you test your answer to determine if it makes sense?
62. * **Galileo's pendulum** The length L of a pendulum is shortened when the string encounters a peg placed a distance b below the support (see Figure P10.62). (a) What is the height to which the bob swings on the other side compared to the height from which it was released? Explain. (b) Derive the expression for the period of the pendulum with the inserted peg. (c) Draw a qualitative position-versus-time graph for three periods of the pendulum's motion. (d) What happens to the force exerted by the string on the bob when the bob passes the equilibrium position? Explain.

FIGURE P10.62



63. * A 0.5-kg low-friction cart is moving at constant speed of 1.7 m/s to the left along a horizontal table toward a relaxed spring with $k = 120$ N/m that is fixed at the left end to a wall. At $t = 0$, the front of the cart is 20 cm from the free end of the spring. The cart hits the spring, and the spring compresses and expands, making the cart move to the right with the same speed as the initial speed. (a) Sketch the situation. Determine the clock reading at the moment when the front (left end) of the cart passes the position where it was at $t = 0$ again. (b) Choose the cart and the spring as a system and represent the process using energy and momentum bar charts. (Hint: Think about which part of the cart's motion can be treated as vibrational motion.)
64. * A circular metal frame is fixed in a vertical position as shown in Figure P10.64a. If a small ice cube is placed inside the frame not too far from the lowest point, it exhibits simple harmonic motion. (a) Draw force diagrams for five positions of the ice cube and compare them with the force diagrams for a simple pendulum in Figure 10.10. (b) Derive the expression for the period of oscillations of the ice cube. (c) How would the melting of the ice cube affect the period of the oscillation, assuming friction can be neglected? Explain.

FIGURE P10.64



65. ** **"Reduced gravity pendulum"** The circular metal frame from Problem 10.64 is now fixed on a smooth incline. If a small ice cube is placed inside the frame as shown in Figure P10.65 and released, it exhibits simple harmonic motion similar to the vertical situation. (a) Draw force diagrams for three positions of the ice cube and compare them with the force diagrams that you obtained in Problem 10.64. (b) Show that the period of oscillation of the ice cube is given by the expression $T = 2\pi\sqrt{\dfrac{R}{g \sin\theta}}$, where R is the radius of the circular frame and θ is the angle of the incline. Why do you think this device is called a "reduced gravity pendulum"?

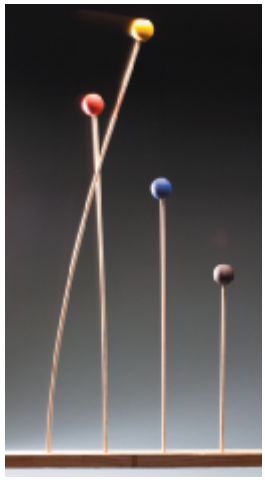
FIGURE P10.65

66. ** You drop a 57-g tennis ball from 1.0 m above a hard concrete floor. For small deformations the ball approximately follows Hooke's law and behaves like a spring with a constant 17×10^3 N/m. Determine (a) by how much the ball compresses during the collision with the floor and (b) the duration of the ball-floor impact. Indicate any assumptions that you made.
67. * A 5.0-g bullet traveling horizontally at an unknown speed hits and embeds itself in a 0.195-kg block resting on a frictionless table. The block slides into and compresses a 180-N/m spring a distance of 0.10 m before stopping the block and bullet. Determine the initial speed of the bullet. State any assumptions that you made to solve the problem.
68. ** You have a pendulum of mass m and length L that is displaced an angle θ at the start of the swinging. (a) Determine an expression for the energy of the bob-Earth system. (b) Determine an expression for the maximum vertical height of the bob with respect to the equilibrium position. (c) Determine an expression for the maximum speed of the bob. (d) What assumptions did you make? (e) Discuss how the answer to each of the questions changes if relevant assumptions are not valid.
69. ** A pendulum clock works for many days before the swinging stops. Describe several mechanisms that allow an actual pendulum clock to continue working without decreasing amplitude. Write a report explaining how it works.
70. ** **Foucault's pendulum** In 1851, the French physicist Jean Foucault hung a large iron ball on a wire about 67 m (220 ft) long to show that Earth rotates. The pendulum appears to continuously change the plane in which it swings as time elapses. Determine the swinging frequency of this pendulum. Explain why the behavior of Foucault's pendulum provides supporting evidence for the hypothesis that Earth is a noninertial reference frame and helps reject the model of a geocentric universe (Earth at the center).
71. ** A low-friction cart of mass m rests on a horizontal table. The cart is attached to a relaxed light spring with spring constant k. At distance d from the first cart rests a second identical cart (see **Figure P10.71**). Both carts are covered with Velcro so they stick together if they collide or touch. The first cart is pushed to the left with initial speed v_0. Determine the final frequency and amplitude of a vibrating system. (Note: This is a multiple possibility problem. Analyze and present all possible solutions.)

FIGURE P10.71

Reading Passage Problems

Transportation to the other side of Earth It has been suggested that an efficient way to travel from the United States to Australia would be to dig one or more holes through Earth and fall through one of the holes in a capsule. The gravitational force that Earth exerts on you and on the capsule when the capsule is at a distance r ($r < R$ of Earth) equals that of the mass M inside a sphere of radius r with its center at Earth's center. At Earth's center, the force is zero. At some other distance r from the center of Earth, the force would be



$$F_{\text{E on Y}} = \frac{GM_{\text{inside }r}m_{\text{Y}}}{r^2}$$

where $M_{\text{inside }r}$ equals the volume of a sphere of radius r times the density of Earth, assumed to be constant. Substituting for $M_{\text{inside }r}$, you find that the force that Earth exerts on you and on the capsule is proportional to r and provides a restoring force. You start at rest at Earth's surface and accelerate as you get closer to the center. At the center you are moving at maximum speed and Earth exerts no force on you. After you pass the center, Earth starts pulling back on you, causing your speed to decrease. With no friction or air resistance, you should stop on the other side of Earth. If you can find an expression for the restoring force that Earth exerts on you, you can substitute that in place of k in the expression for period $T = 2\pi(m/k)^{1/2}$. The travel time will be half the period.

72. Which expression below represents the mass m of Earth inside a sphere of radius r smaller than the radius R of Earth? Note that ρ is the density of Earth, assumed uniform.
(a) $(4/3)\pi r^3\rho$ (b) $G(4/3)\pi r^3\rho$
(c) GM_{Earth}/r^2 (d) $G(4/3)\pi r\rho$
(e) mg
73. Which expression below represents the magnitude of the restoring force that Earth exerts on an object of mass m when a distance r from the center of Earth? Note that ρ is the density of Earth, assumed uniform.
(a) $m(4/3)\pi r^3\rho$ (b) $mG(4/3)\pi r^3\rho$
(c) $GM_{\text{E}}m/r^2$ (d) $mG(4/3)\pi r\rho$
(e) mgr
74. Which expression below represents the period T for one oscillation from Earth's surface through the center, to the other side, and then back again?
(a) $2\pi(3/G4\pi\rho)^{1/2}$ (b) $2\pi(G4\pi\rho/3)^{1/2}$
(c) $2\pi(3m/G4\pi\rho)^{1/2}$ (d) $2\pi(mG4\pi\rho/3)^{1/2}$
(e) $2\pi(m/k)^{1/2}$
75. During the trip, when will your acceleration be greatest?
(a) At the beginning and end of the trip
(b) At the end of the trip
(c) When passing through the center of Earth
(d) The same for entire the trip
76. During the trip, when will your speed be greatest?
(a) At the beginning and end of the trip
(b) At the end of the trip
(c) When passing through the center of Earth
(d) The same for entire the trip
77. If the radius of Earth is 6.4×10^6 m, its mass is 6.0×10^{24} kg, and $G = 6.67 \times 10^{-11}$ N·m^2/kg^2, what is the time interval for one trip through Earth?
(a) 0.7 h (b) 1.4 h
(c) 3.2 h (d) 4.8 h
(e) 6.3 h

BIO **Resonance vibration transfer and the ear** When you push a person on a swing, a series of small pushes timed to match the swinger's swinging frequency makes the person swing with larger amplitude. If timed differently, the pushing is ineffective. The board shown in **Figure 10.17** (from the Exploratorium in San Francisco) is made of rods of different length with identical balls on the ends of each rod. Each rod vibrates at a different natural frequency, the long rod on the left at lower frequency and the short rod on the right at higher frequency. If you shake the board at the high frequency at which the short rod vibrates, the short rod swings with large amplitude while the others swing a little. If you shake the board at the middle frequency at which the two center rods vibrate, the center rods undergo large-amplitude vibrations and the rods on each end do not vibrate. Imagine now that you have a fancy board with 15,000 rods, each of slightly different length, the shortest on the left and the longest on the right. Shaking the board at a particular frequency causes the rods in one small region of the board to vibrate at this frequency and has little effect on the others.

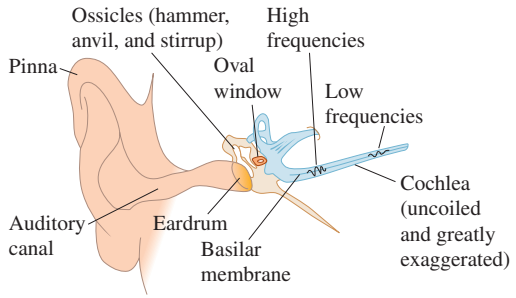


FIGURE 10.17 Coupled oscillations of the shaking board and rods.

The short rod with a ball on the end responds to higher frequency shaking of the board, whereas the middle length rods respond to intermediate frequency shaking.

The inner ear (the cochlea) is a little like this fancy board. Sound reaching the tympanic membrane, or eardrum, is greatly amplified by three tiny bones in the middle ear—the hammer, anvil, and stirrup (**Figure 10.18**). These bones vibrate, pushing on the fluid in the inner ear and causing vibrations along its entire length. A basilar membrane with about 15,000 hair cells passes along the center of the inner ear. The basilar membrane is narrow and stiff near the entrance to the inner ear and wide and more flexible near the end. When a single-frequency vibration causes the fluid to vibrate, the membrane and the hair cells respond best at a single place—high frequencies near the oval window and low frequencies near the end of the basilar membrane. The bending of these hairs causes those nerve cells to fire. Thus, we detect the frequency of the sound by the part of the membrane from which the nerve signal comes.

FIGURE 10.18 Anatomy of the human ear.

78. What causes vibrations in the fluid in the cochlea?
    (a) The eardrum pushes against the cochlea.
    (b) Sound waves push against the cochlea.
    (c) A bone in the middle ear pushes against the cochlea.
    (d) The fluid vibrates when something outside the ear vibrates.
    (e) The fluid does not vibrate—the hair cells vibrate.

79. How does the basilar membrane distinguish different frequency vibrations?
    (a) The hair cells have different lengths.
    (b) The dimensions and stiffness of the cochlea vary along its length.
    (c) The basilar membrane vibrates where the cochlea dimension and stiffness match the vibration frequency.
    (d) The cochlea fluid resonates in only one part of the cochlea.
    (e) All the hair cells bend back and forth at only the frequency of the vibration.

80. If you shake the board shown in Figure 10.17 at a frequency higher than the natural frequency of the rod on the right, then what happens?
    (a) None of the rods vibrate.
    (b) All of the rods vibrate.
    (c) The shortest rod vibrates.
    (d) The longest rod vibrates.
    (e) The middle rods vibrate.

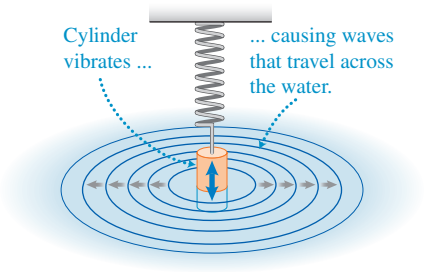
81. If you were to shake the special board (the one that has 15,000 rods of varying length) at one particular frequency, then what would happen?
    (a) None of the rods would vibrate.
    (b) All of the rods would vibrate.
    (c) A small number of rods at one location would vibrate.
    (d) A disturbance would travel back and forth along the board.

82. You hang four pendulum bobs from strings connected to a wooden dowel. The strings are different lengths. How can you get the second longest pendulum bob to vibrate while the other three do not—without touching the pendulums?
    (a) Shake the dowel back and forth.
    (b) Shake the dowel back and forth at the resonant frequency of that pendulum.
    (c) Move the dowel sideways at any frequency.
    (d) Blow air on that bob.

11

Mechanical Waves

You have probably heard the expression "blind as a bat." It turns out that bats are not blind; many species have very sensitive eyes that can see even when there is very little light. However, the organs that bats use to avoid obstacles at night and find their prey are their ears. While flying, they emit sound that travels to the prey, reflects, and travels back to the bat. The bat's brain processes the delay time and automatically calculates the distance to the prey. Why don't we ever hear the sounds produced by bats?



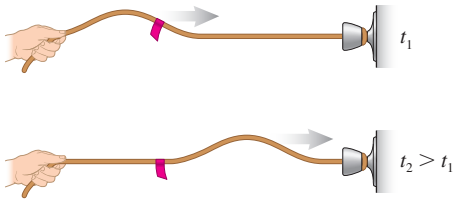
- **How do bats "see" in the dark?**
- **How can you transmit energy without transmitting matter?**
- **Why does the pitch of a train whistle change as the train passes you?**

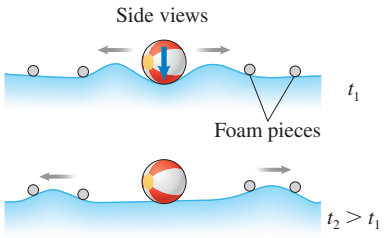
PREVIOUSLY (IN CHAPTER 10), we studied the vibrational motion of one object such as a pendulum or a cart attached to a spring. We have not considered what happens to the environment that is in contact with the vibrating object. In this chapter we will focus on the effect that the vibrating object has on the medium that surrounds it. An example of such an effect is the propagation of sound.

BE SURE YOU KNOW HOW TO:

- Describe simple harmonic motion verbally, graphically, and algebraically (Section 10.3).
- Determine the period and amplitude of vibrations using a graph (Section 10.2).
- Determine the power of a process (Section 7.8).

FIGURE 11.1 A vibration disturbs the surrounding medium.





11.1 Observations: pulses and wave motion

Our everyday experience indicates that when an object vibrates, it also disturbs the medium surrounding it. We call the object that causes the vibration the **source**. For example, place a heavy metal cylinder attached to a spring so that the cylinder is partially submerged in a tub with water (**Figure 11.1**). Push down on the cylinder a little and release it. The vibrating cylinder (the source) sends ripples (waves) across the tub. In Observational Experiment **Table 11.1** we observe the simplest case of wave motion—when the source of waves vibrates only once, sending a short disturbance, or a **pulse**, into the surrounding medium.

OBSERVATIONAL EXPERIMENT TABLE 11.1 Disturbances in different media

VIDEO OET 11.1

Observational experiment	Analysis
Experiment 1. Tie a rope to a doorknob and then shake the end that you are holding one time, producing a quick disturbance—a pulse. The pulse travels along the rope horizontally. The part of the rope marked with a ribbon moves up and down when the pulse reaches it. 	The source of the pulse is your hand pulling the rope; the medium in which the pulse propagates is the rope itself. The pulse moves along the rope, but the rope fibers (see the little ribbon on the rope) return to their original position after the disturbance passes—they do not travel along the rope. It takes time for the pulse to travel to the other end of the rope.
Experiment 2. Place a beach ball and polystyrene foam pieces on the surface of a swimming pool. Push the ball down once. A pulse in the shape of a circular disturbance spreads outward. The foam pieces bob up and down but do not travel across the pool. 	The source of the pulse is the ball; the medium is the surface layer of water in the pool. The circular disturbance produced by the ball's downward motion spreads; the water itself does not move across the pool, as the foam pieces on the water surface only move up and down. It takes time for the pulse to reach the far sides of the pool.

Patterns

In the two experiments, we saw that
- a moving disturbance was created by a moving source—your hand or the ball.
- the disturbance moved through a material at an observable speed.
- the particles of the medium vibrate close to their original position, but do not travel far.

Waves and wave fronts

In the beach ball experiment, when the vibrating ball (the source) moves down, the water (the medium) under the ball's bottom surface is pushed out to the side of the ball, forming a hump in the water at the sides of the ball. This hump falls back toward its equilibrium level and overshoots, pushing water slightly farther away upward into a hump. This disturbance propagates outward, but the water at a particular location mostly vibrates up and down, and not outward in the direction the wave travels. The vibrating source and the interactions of the neighboring sections of the medium result in a coordinated vibration—a wave. The interaction between the parts of the medium is crucial—without it, the wave would not propagate. If you cut the rope just after shaking its end, the disturbance will not propagate. We can now define wave motion:

Wave motion involves a disturbance produced by a vibrating object (a source). The disturbance moves, or propagates, through a medium and causes points in the medium to vibrate. When the disturbed medium is physical material (solid, liquid, or gas), the wave is called a **mechanical wave**.

The moving circular disturbance itself created by the beach ball on the water is called a **wave front** (see the top view in **Figure 11.2a**). Every point on the wave front has the same displacement from equilibrium at the same clock reading. If instead of pushing the ball one time, you push it down and up in a regular pattern, you will see a continuous group of humps and dips (waves consisting of many wave fronts) of circular shape moving outward on the surface of the water (Figure 11.2b).

Two kinds of waves

The stretchy toy called a Slinky provides another good example of wave motion. If we (the source) push or pull the end coil of a stretched Slinky (the medium) several times, it will pull the coil attached to it. That coil pulls the next coil, which in turn pulls the next coil, and so on. We see a compressing and stretching pattern moving along the Slinky toy in the direction of wave propagation. The pattern is illustrated in **Figure 11.3** at a single moment in time. Such a wave is called a **longitudinal wave**.

We can disturb a Slinky in a different way. If we vibrate the coil up and down perpendicular to the length of the Slinky, the coils move up and down perpendicular to the direction that the disturbance travels (**Figure 11.4**). This type of wave is called a **transverse wave**.

Longitudinal and transverse waves In a longitudinal wave the vibrational motion of the particles or layers of the medium is parallel to the direction of propagation of the disturbance. In a transverse wave the vibrational motion of the particles or layers of the medium is perpendicular to the direction of propagation of the disturbance.

FIGURE 11.2 Wave fronts move outward from the source.

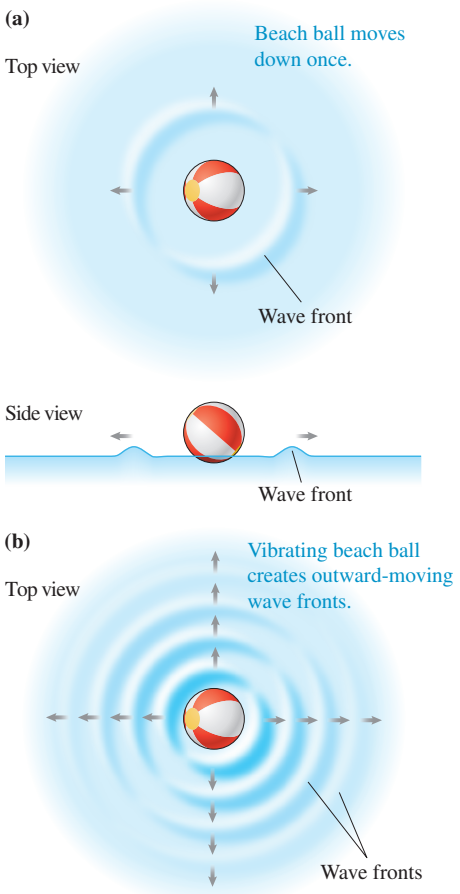


FIGURE 11.3 A longitudinal wave on a Slinky.

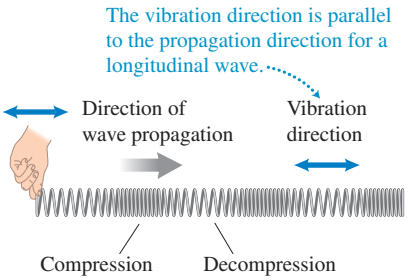

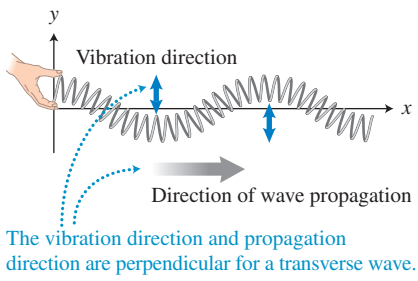

FIGURE 11.4 A transverse wave on a Slinky.

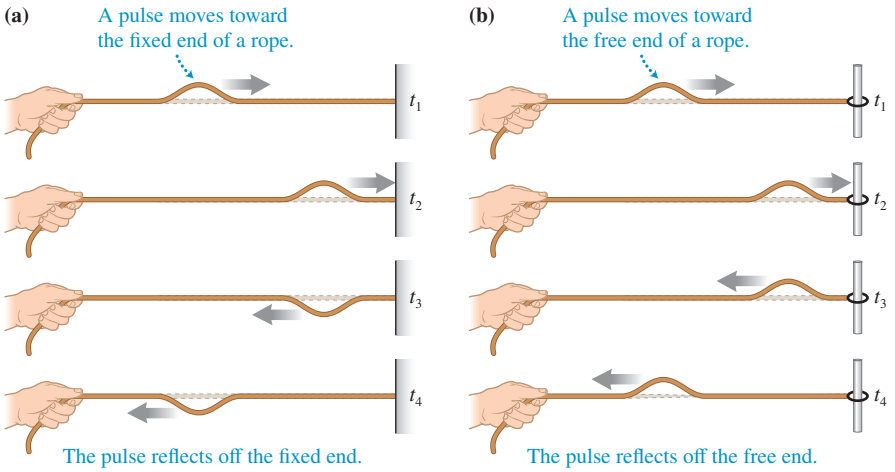
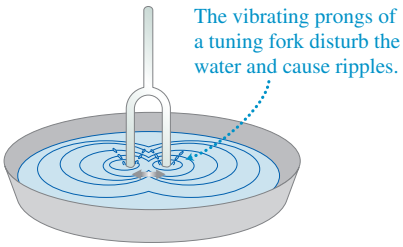


Reflection of waves

We observe another important property of waves when watching waves on the surface of the water, on a Slinky, or on a rope. When a wave reaches the wall of the container or the end of the Slinky or rope, it reflects off the end and moves in the opposite direction. In fact, when a wave encounters any boundary between different media, some of the wave is reflected back. **Figure 11.5a**, on the next page, shows this reflection for one pulse on a rope when the rope is attached to a wall. However, even if there is no wall, the pulse reflects off the end of the rope. Think of a rope that ends with a ring that can slide without friction along a vertical pole (Figure 11.5b). The reflected pulse is now upright and not inverted as it was in Figure 11.5a. If you continue shaking the rope, continuously producing pulses, you will create a wave. The wave traveling to the right and the reflected wave traveling to the left exist in the rope simultaneously, complicating the analysis. (Watch the video of a similar experiment using a Slinky). Thus, if we want to study simple wave motion and not worry about reflected waves, we need to have a very long medium.

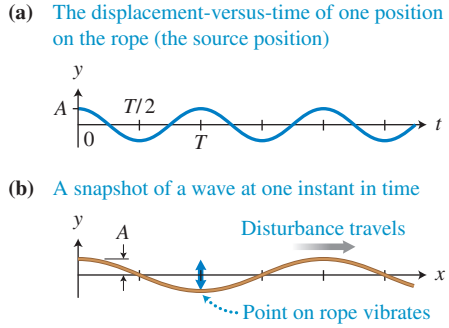


VIDEO 11.1

FIGURE 11.5 A pulse on a rope at different times.

Sound waves

FIGURE 11.6 A vibrating tuning fork produces sound along with waves on the surface of the water.



You have probably seen a tuning fork, a device used to tune musical instruments. If you strike a tuning fork, you hear sound. You can feel the vibrations of the prongs if you touch them. In fact, the moment you touch them, the sound stops, since you've stopped their vibrations. If you place the vibrating prongs in water, you see ripples going out (**Figure 11.6**). The tuning fork is a source of waves. What happens to cause our ears to hear a sound? The vibration of the tuning fork compresses and decompresses air around it. We will learn in the next chapter that in compressions, air molecules come closer together, and in decompressions, air molecules spread farther apart. These longitudinal compressions and decompressions (similar to what we observed on the Slinky) move through the air and reach our ears, and we perceive them as sound. Sound propagates in water (it's how dolphins communicate) and even in solid objects (seismic waves in Earth). If a tuning fork vibrates in a vacuum, there will be no medium for the tuning fork prongs to vibrate against and consequently no way for air compressions and decompressions to occur. Thus sound cannot propagate in a vacuum. We will study sound waves in more detail later in the chapter.

REVIEW QUESTION 11.1 How do you produce a longitudinal wave on a Slinky? How do you produce a transverse wave?

11.2 Mathematical descriptions of a wave

FIGURE 11.7 A wave produced on a rope by a vibrating source.

To understand waves and predict their behavior, we need to describe them using physical quantities and find relationships between those physical quantities.

We will use the waves traveling along a very long rope (so long that we can ignore reflected waves) and a wave source that vibrates with simple harmonic motion (SHM; discussed in Chapter 10). This motion can be created by a motor that vibrates the end of a rope up and down perpendicular to the rope. The motor (the source) produces a transverse wave in the rope (the medium). At time zero, the source starts at $y = +A$. The source vibrates sinusoidally; thus the source displacement is described by a sinusoidal function of time (**Figure 11.7a**):

$$y = A\cos\left(\frac{2\pi}{T}t\right) \tag{11.1}$$

where y is the displacement of that end of the rope from its equilibrium position, A is the amplitude of the vibration, and T is the period of vibration. The left end of the

rope moves up and down, pulling the next part of the rope, which pulls its neighboring part, which pulls its neighboring part, and so on. The wave propagates along the rope at a particular speed, so that when the disturbance reaches a point at a distance x from the source, that point starts vibrating at the same period T as the source. Figure 11.7b shows a snapshot of the resulting wave at some arbitrary time t. We now have four quantities that describe the wave started by this vibrating source. The first three are familiar to us from Chapter 10: they describe the motion of a vibrating object. The fourth quantity (speed), as it applies to waves, is new.

Period T in seconds is the time interval for one complete vibration of a point in the medium anywhere along the wave's path.

Frequency f in Hz (s^{-1}) is the number of vibrations per second of a point in the medium as the wave passes.

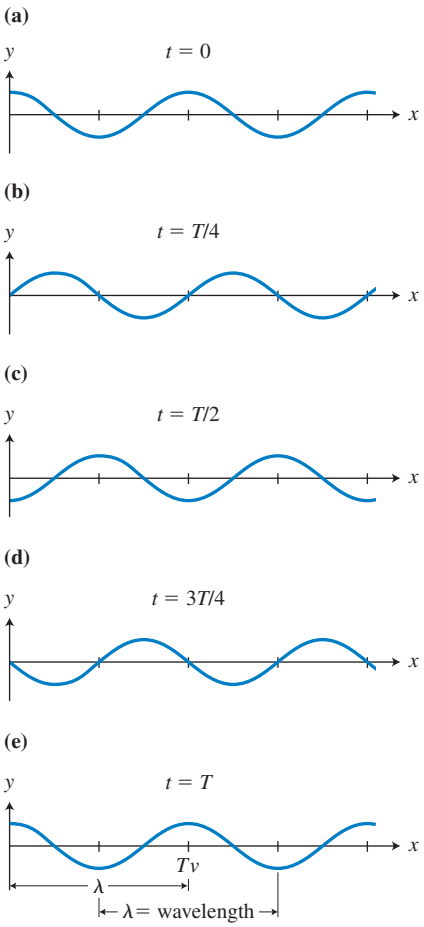
Amplitude A is the maximum distance of a point of the medium from its equilibrium position as the wave passes.

Speed v in m/s is the distance a disturbance travels during a time interval, divided by that time interval.

TIP Note that the definition of the amplitude given here only works for waves on rope or a Slinky. For sound waves, we will learn a new definition.

Mathematical description of a one-dimensional traveling sinusoidal wave

Our goal is to construct a description of a traveling sinusoidal wave at different places along its path and at different times (clock readings). For simplicity, we only consider one-dimensional waves, such as waves on ropes or Slinkys, and we will assume that the mechanical energy of the source is not converted to the internal energy of the medium. In other words, no damping occurs—the amplitude of the vibration is the same at all points. We also assume that the speed of the wave propagation is constant throughout the medium. We choose the positive x-direction as the direction in which the disturbance travels at speed v. The left end of the rope at $x = 0$ is attached to the vibrating source. According to Eq. (11.1), the source oscillates up and down with a vertical displacement



$$y(0, t) = A\cos\left(\frac{2\pi}{T}t\right)$$

The zero in the parentheses indicates that the function $y(0, t)$ describes the motion of the medium at the position $x = 0$ and clock reading t. The shape of the rope at five different times is shown in **Figure 11.8**. If you look at any other position along the x-axis, the rope vibrates in the same way as it does at $x = 0$ but at a different instant in the vibration cycle. For example, at the first tick mark to the right of $x = 0$, you see that at time zero, the rope displacement is $-A$; at time $t = T/4$, its y-displacement is zero, then $+A$, then 0, and finally back to $-A$.

We can mathematically describe the disturbance $y(x, t)$ of a point of the rope at some positive position x to the right of $x = 0$ at some arbitrary time t. Every point to the right of $x = 0$ vibrates with the same frequency, period, and amplitude as the rope at $x = 0$. But there is a time delay $\Delta t = x/v$ for the disturbance at $x = 0$ to reach the location x. The vibrational disturbance at position x at time t is the same as the disturbance at $x = 0$ was at the earlier time $t - x/v$. Thus, the vibration of the rope at position x can be described as

$$y(x, t) = A\cos\left[\frac{2\pi}{T}\left(t - \frac{x}{v}\right)\right] \qquad (11.2)$$

FIGURE 11.8 The shape of a transverse wave at five consecutive times.

The snapshot graph of the disturbance (Figure 11.8e) shows that the disturbance pattern repeats at a distance Tv (period multiplied by the wave speed). This distance separates neighboring locations on the rope that have the same displacement y and the same slope. This distance is called the **wavelength** of the wave and is represented by the Greek letter λ (lambda):

$$\lambda = Tv = \frac{v}{f}$$

where v is the speed of travel of the wave, T is the period of vibration of each part of the rope, and f is the frequency of vibration $(1/T)$.

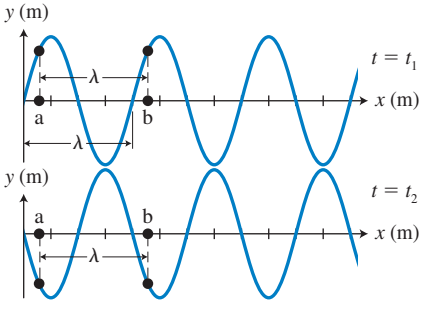
TIP You can think of a wavelength as the distance that the wave propagates during one period. It is helpful to remember the equation $\Delta x = v\,\Delta t$.

Wavelength λ equals the distance between two nearest points on a wave that at any clock reading have exactly the same displacement and shape (slope). It is also the distance between two consecutive wave fronts:

$$\lambda = Tv = \frac{v}{f} \tag{11.3}$$

We can substitute this expression for wavelength into Eq. (11.2) and rearrange a little to get a function of the two variables t and x that allows us to predict the displacement y of any point x at any time t in a medium through which the wave propagates:

$$y(x, t) = A\cos\left[\frac{2\pi}{T}\left(t - \frac{x}{v}\right)\right] = A\cos\left[2\pi\left(\frac{t}{T} - \frac{x}{Tv}\right)\right] = A\cos\left[2\pi\left(\frac{t}{T} - \frac{x}{\lambda}\right)\right]$$



Mathematical description of a traveling sinusoidal wave The displacement from equilibrium y of a point at location x at time t when a wave of period T travels at speed v in the positive x-direction through a medium is described by the function

$$y = A\cos\left[2\pi\left(\frac{t}{T} - \frac{x}{\lambda}\right)\right] \tag{11.4}$$

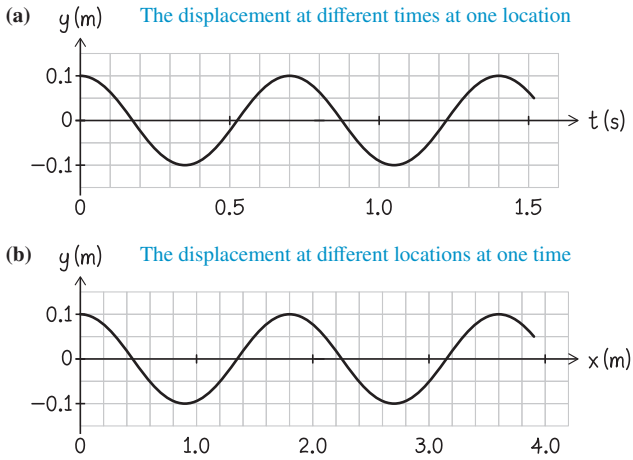
The wavelength λ of this wave equals $\lambda = T \cdot v$.

TIP Notice that Eq. (11.4) is mathematically symmetric with respect to the period of the wave and its wavelength because there are two repetitive processes in a wave. If the location x is fixed, that point in the medium vibrates in time with period T. If the time t is fixed (as in a photograph), the space has a wavelike appearance with wavelength λ (see Figure 11.8). We replaced the notation for the function $y(x, t)$ with just y for simplicity.

FIGURE 11.9 Two snapshots of the same wave. Points a and b have the same phase at any clock reading.

In Eq. (11.4), at any fixed time t, the term $2\pi x/\lambda$ describes the difference, in units of radians, between the displacement of a vibrating point at position x and the displacement at the origin, and is called a **phase**. This term has the effect of shifting the cosine function by some number of radians. When x is equal to an integer multiple n of the wavelength, the term equates to an integer multiple of 2π. Shifting the cosine function by a multiple of 2π has no effect, so a point vibrating at position $x = n\lambda$ is said to be *in phase* with the origin. Therefore, two points separated by a distance equal to an integer multiple of wavelengths (one wavelength, two wavelengths, etc.) are always in phase (**Figure 11.9**).

CONCEPTUAL EXERCISE 11.1 **Making sense of a mathematical description of a wave**



A transverse wave on an infinitely long Slinky is described mathematically as

$$y = (0.10\text{ m})\cos\left[2\pi\left(\frac{t}{0.70\text{ s}} - \frac{x}{1.8\text{ m}}\right)\right]$$

Say everything you can about this wave and represent it graphically.

Sketch and translate Compare the given equation with the wave equation [Eq. (11.4)]: $y = A\cos\left[2\pi\left(\frac{t}{T} - \frac{x}{\lambda}\right)\right]$. Therefore, $A = 0.10$ m, $T = 0.70$ s, and $\lambda = 1.8$ m. We can also say that at $t = 0$, the starting point with the coordinate $x = 0$ had a displacement of $y(0, 0) = (0.10\text{ m})\cos\left[2\pi\left(\frac{0}{0.70\text{ s}} - \frac{0}{1.8\text{ m}}\right)\right] = 0.10$ m. We can write a mathematical equation for the motion of the wave source at location $x = 0$: $y_{\text{source}} = (0.10\text{ m})\cos\left[2\pi\left(\frac{t}{0.70\text{ s}}\right)\right]$. Notice that at $x = 0$, y is a function of time only, as we are looking at the disturbance at only one location. Rearranging the equation $\lambda = Tv$, we get $v = \lambda/T = (1.8\text{ m})/(0.70\text{ s}) = 2.6$ m/s, a reasonable number.

Simplify and diagram Knowing the amplitude and the period, we can draw a displacement-versus-time (clock reading) graph for one particular location in the medium (we do it for $x = 0$ in the first figure at right). Knowing the amplitude and the wavelength, we can draw a graph that represents an instantaneous picture of the whole Slinky at a particular time (clock reading) (shown for $t = 0$ in the second figure).

Try it yourself A Slinky vibrates with amplitude 15 cm and period 0.50 s. The speed of the wave on the Slinky is 4.0 m/s. Write the wave equation for the Slinky.

Answer $y = (0.15\text{ m})\cos\left[2\pi\left(\frac{t}{0.50\text{ s}} - \frac{x}{2.0\text{ m}}\right)\right]$.

TIP Because Eq. (11.4) is a function of two variables, when we represent waves graphically we need two graphs, such as those in the figures in Exercise 11.1—one showing how one point of the medium changes its position with time (y versus t; x = constant) and the other one showing the displacements of multiple points of the medium at the same clock reading—a snapshot of the wave (y versus x; t = constant).

REVIEW QUESTION 11.2 Compare and contrast the speed of a vibrating object and the speed of a wave.

11.3 Dynamics of wave motion: speed and the medium

We have defined the speed of a wave as the distance that a disturbance travels in the medium during a time interval divided by that time interval. This operational definition of speed tells us how to determine the speed but does not explain what determines the wave speed. To answer this question, we will investigate transverse waves on a rope or a Slinky via the following experiment.

Figure 11.10 shows two people holding the ends of a Slinky pulling on both ends so that the Slinky is taut. The person on the left shakes the end of the Slinky abruptly and sends several repeated pulses along the Slinky; the person on the right measures the force pulling on the Slinky and the time interval Δt needed for a pulse to travel the distance L. They vary the amplitude, the frequency, and the magnitude of the pulling force

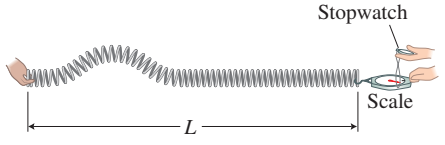


FIGURE 11.10 Investigating the speed of pulse propagation on a Slinky.

one at a time. The data that they collect are presented below in **Table 11.2**. Notice that when they increase the force, the distance that the pulse travels also increases, because they have to stretch the Slinky more.

TABLE 11.2 How do different physical quantities affect the speed of pulse propagation?

Experiment	A (m)	f (Hz)	F (N)	L (m)	Δt (s)	v (m/s)
1: Changing A	0.3	4.0	5.0	1.3	0.36	3.6
2: Changing A	0.2	4.0	5.0	1.3	0.36	3.6
3: Changing A	0.1	4.0	5.0	1.3	0.36	3.6
4: Changing f	0.1	3.0	5.0	1.3	0.36	3.6
5: Changing f	0.1	2.0	5.0	1.3	0.36	3.6
6: Changing F	0.1	2.0	6.0	1.6	0.36	4.3
7: Changing F	0.1	2.0	7.0	1.9	0.36	5.0

There are three important patterns that we can infer from the table:

- Experiments 1–3: the speed of the wave does not depend on the amplitude of the pulses.
- Experiments 3–5: the speed of the wave does not depend on the frequency of the pulses.
- Experiments 5–7: the speed of the wave changes when both the length and the force exerted on the Slinky change.

These patterns are surprising—the speed of the pulse does not depend on the amplitude of the pulse or on its frequency. The amplitude and the frequency only depend on the source of the waves. Therefore, we can conclude that the source of the waves does not affect the speed of the wave on the Slinky!

However, pulling harder on the end of the Slinky does increase the wave speed. In addition, as we stretch the Slinky, the coils spread farther apart, reducing the Slinky's *linear density*—its mass per unit length. The force pulling on the Slinky and its linear density seem to affect the speed of a pulse or wave on the Slinky. Knowing that both of these quantities affect the speed, we should be careful not to conclude from Table 11.2 that the speed is linearly proportional to the force. As you pull harder on the spring, the length increases proportionally (with no change in mass), so the linear density decreases proportionally to the force.

If we do similar experiments with stiff springs that stretch less than a Slinky, we find that the wave speed is proportional to the square root of the force pulling on the end of the spring. This applies to other objects as well, such as strings:

$$v \propto \sqrt{F_{\text{M on M}}}$$

The subscripts M and M indicate the pulling force that one part of the medium (M) exerts on a neighboring part of the medium (M) when two people stretch the spring. This result makes sense—the more you pull on the spring, the more strongly adjacent parts interact with each other and therefore the faster they transfer the disturbance.

Other experiments indicate that speed is also affected by the linear density of the medium. The speed of a wave is inversely proportional to the square root of the linear density of the medium:

$$v \propto \frac{1}{\sqrt{\frac{m}{L}}} = \frac{1}{\sqrt{\mu}}$$

Here the Greek letter μ is used for the linear density (m/L) (note that in other contexts this symbol is used to denote the coefficient of friction). The dependence on mass

TIP Do not confuse the force you exert to stretch the Slinky to create some tension with the force you exert on its end when you are creating a pulse. The speed of the wave is affected by the former, not the latter.

makes sense in terms of Newton's second law. The greater the mass of a part of the medium, the smaller the acceleration of that part and the longer the time needed to move the next part. We can combine these two factors into one equation:

$$v = \sqrt{\frac{F_{\text{M on M}}}{\mu}}$$

Let us check whether the units are correct:

$$v = \sqrt{\frac{\text{N}}{\text{kg/m}}} = \sqrt{\left(\frac{\text{kg} \cdot \text{m}}{\text{s}^2}\right)\left(\frac{\text{m}}{\text{kg}}\right)} = \frac{\text{m}}{\text{s}}$$

The units are correct. To make sure that the speed does in fact depend on the above properties, we perform the following experiment. We take a rope of known mass and length, attach one end to a wall, and pull the other end with a spring scale, exerting a known force. Then we pluck the rope once, sending a pulse. We determine the speed of the pulse using the time and distance data and compare to the speed that we calculate using the expression above. The match of the results shows that the coefficient of proportionality in the equation is 1.

Wave speed The speed v of a wave on a string or in some other one-dimensional medium depends on how hard the string or medium is pulled $F_{\text{M on M}}$ (one part of the medium pulling on an adjacent part) and on the mass per unit length $\mu = m/L$ of the medium:

$$v = \sqrt{\frac{F_{\text{M on M}}}{\mu}} \tag{11.5}$$

TIP Note two mathematical expressions for the speed of the pulse:

$v = d/\Delta t$ and $v = \sqrt{\frac{F_{\text{M on M}}}{\mu}}$

The first expression is an operational definition for speed, while the second is a cause-effect relationship.

We have just learned that the speed of waves in a medium in which no mechanical energy is converted into internal energy depends only on the properties of the medium. The period and frequency of a wave depend on the vibration source. Since the medium vibrates at the same frequency as the source, the wavelength of the wave depends on both the frequency of the source and the speed of the wave through the medium. If the vibration frequency is low and the wave speed high, the crest of the wave will travel a greater distance before the next crest leaves the source. Thus the wavelength is large:

$$\lambda = \frac{v}{f}$$

However, if the wave speed is low and/or the frequency high, the wavelength is small:

$$\lambda = \frac{v}{f}$$

The wave speed also depends on the type of wave (or pulse). In the same medium, transverse waves (and pulses) travel more slowly than longitudinal waves (and pulses). The reason for the difference is in the types of deformation of the medium that occur when the waves propagate. The transverse waves that can only propagate in solids require shear deformation—the layers of the medium slide across each other—while the longitudinal waves require compressions and decompressions. The respective forces that parts of the medium exert on each other for the shear deformations are weaker than for the compressions/decompressions.

TIP The equation $\lambda = Tv = \frac{v}{f}$ is a cause-effect relationship for the wavelength.

QUANTITATIVE EXERCISE 11.2 **Effects of tension force exerted on a violin G string**

A violin G string is 0.33 m long and has a mass of 2.2 g. Determine the tension force exerted on the ends of the string in order for a wave to travel at the speed of 128 m/s.

Represent mathematically We know that

$$v = \sqrt{\frac{F_{\text{S on S}}}{\mu}} = \sqrt{\frac{F_{\text{S on S}}}{m/L}}$$

Rearrange this to determine the magnitude of the tension force $F_{\text{S on S}}$ that adjacent parts of the string exert on each other and that the peg at the end of the violin exerts on the string.

Solve and evaluate Rearranging the above equation, we get

$$F_{\text{S on S}} = \frac{m}{L}v^2 = \frac{(2.2 \times 10^{-3}\,\text{kg})}{(0.33\,\text{m})}(128\,\text{m/s})^2$$
$$= 110\,\text{kg}\cdot\text{m/s}^2 = 110\,\text{N}$$

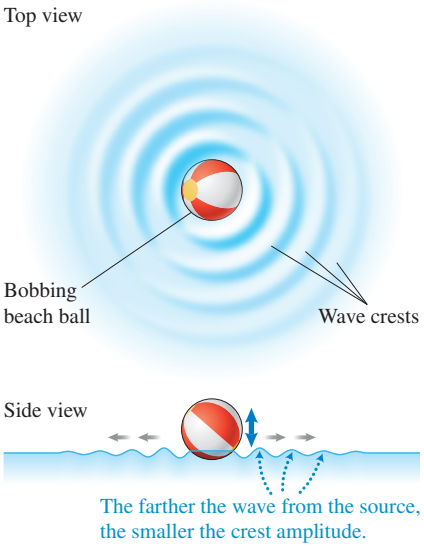
This is a reasonable tension (about 20 lb), and the unit is correct.

Try it yourself Would the force exerted on the end of a 1.4-g violin A string be higher or lower if the waves traveled at a speed of 288 m/s?

Answer Higher—about 350 N.

REVIEW QUESTION 11.3 How do we define wavelength operationally? What affects the value of the wavelength of a wave? How do you write a cause-effect relationship for the wavelength?

FIGURE 11.11 Wave crests are shown at one instant in time on the surface of water.



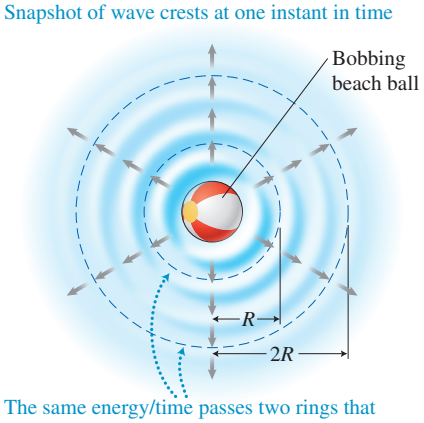


FIGURE 11.12 The wave crest amplitude decreases on a two-dimensional surface with distance from the source.

11.4 Energy, power, and intensity of waves

So far we have investigated quantitatively waves that propagate in a one-dimensional medium such as a rope. If there is no damping of the vibrations as the wave propagates, then the amplitude of the vibration at any point in the one-dimensional medium is the same as that of the source. What happens if the wave propagates without damping through a two-dimensional medium (like the surface of a small lake) or a three-dimensional medium (like the air surrounding a balloon that pops and produces sound)? Do the amplitudes of these waves remain constant as they propagate outward from the source?

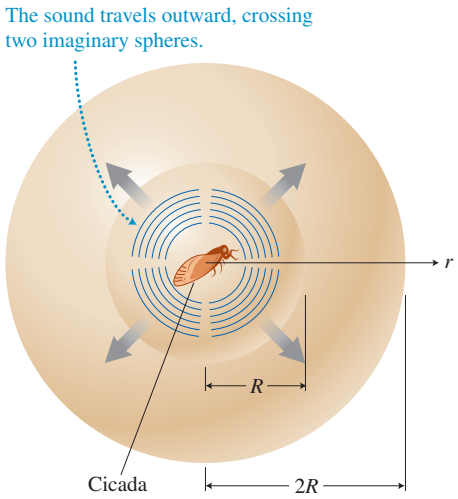
Wave amplitude and energy in a two-dimensional medium

Consider **Figure 11.11**. A beach ball bobs up and down in water in simple harmonic motion, producing circular waves that travel outward across the water surface in all directions. The shaded circles represent the peaks of the waves. We observe that the amplitudes of the crests decrease as the waves move farther from the source. Why?

Suppose that the wave source uses 10 J of energy E every second to produce a pulse, and that all of that energy is transferred to the pulse (one pulse per second). As the pulse propagates outward in all directions, more particles vibrate, since the circumference of the circular pulse increases as it gets farther from the source. However, the total energy of all vibrating particles in the pulse cannot exceed 10 J. Since there are more vibrating particles as the pulse moves outward, the vibrational energy per particle has to decrease.

To do a quantitative analysis, we surround the source with two imaginary rings (the dashed lines in **Figure 11.12**), one at a distance R from the source and the other at distance $2R$. If the energy output of the source per unit time is 10 J/s, then this energy first moves through the circumference $C_1 = 2\pi R$ and then through the second larger circumference $C_2 = 2 \cdot 2\pi R = 2C_1$. The circumference of the second ring is two times greater than the first, but the same energy per unit time moves through it. Consequently, the energy per unit circumference length (energy/C = energy/$2\pi r$)

passing the second ring is one-half that passing the first ring. We see that the energy per unit time and per unit circumference length is inversely proportional to the distance from the source (assuming that there is no damping).



Two-dimensional waves produced by a point source The energy E per unit circumference length and per unit time crossing a line perpendicular to the direction that the wave travels decreases as $1/r$, where r is the distance from the point source of the wave.

In Chapter 10 we learned that the amplitude of vibrations and the energy of the vibrating system are related to each other. Thus, if the energy per circumference length and per unit time of a two-dimensional wave decreases as the wave propagates, so should the amplitude. Remember that another reason for amplitude decrease is damping.

Wave amplitude and energy in a three-dimensional medium

Consider a three-dimensional medium. You hear a cicada (an insect that makes a loud sound in the summer) sitting on top of a bush that is about the same height as you. It is a source of sound that is propagating in all directions. Consider two imaginary spheres that surround the source (**Figure 11.13**), one at distance R from the source and the other at distance $2R$. Assume that the energy output of the source per unit time is 10 J/s. This energy first moves through the surface area $A_1 = 4\pi R^2$ and then through the second larger area $A_2 = 4\pi(2R)^2 = 4A_1$. The area of the second sphere is four times the first, but the same energy per unit time moves through it. Consequently, the energy per unit area through the second sphere is one-fourth that through the first sphere. The energy per unit time per unit area is inversely proportional to the distance squared from the source. This conclusion is consistent (qualitatively) with our experience: we know that the farther we are from the cicada, the quieter the sound becomes.

FIGURE 11.13 The sound decreases in amplitude and loudness at a greater distance from the source.

Three-dimensional waves produced by a point source The energy E per unit area per unit time passing across a surface perpendicular to the direction that the wave travels decreases as $1/r^2$, where r is the distance from the point source of the wave.

TIP The symbol for the area and the amplitude of vibrations is the same—A. Make sure you interpret the meaning of A based on the context of the situation.

QUANTITATIVE EXERCISE 11.3 Spreading waves from a cicada

A cicada sits on a bush that is about your height. How far away from the bush should you stand so that the energy of the cicada's sound that you hear is 10 times less than when you are standing 5.0 m away from the bush?

Represent mathematically The energy of the sound waves emitted by the cicada moves through larger and larger surface areas. We know that the energy per area per unit time passing across a surface perpendicular to the direction that the wave travels decreases as $1/r^2$, where r is the distance from the point source of the wave. Thus we can represent this decrease of energy passing through a unit area mathematically as

$$\frac{E_{r2}}{E_{r1}} = \frac{(1/r_2^2)}{(1/r_1^2)} = \frac{r_1^2}{r_2^2}$$

Taking the area of the opening of your ear as a unit area in this case, and the ratio of the energies to be $\frac{E_{r2}}{E_{r1}} = \frac{1}{10}$, we can use this equation to find the distance.

Solve and evaluate Inserting the known r_1:

$$\frac{E_{r2}}{E_{r1}} = \frac{(r_1^2)}{(r_2^2)} = \frac{(5.0\text{ m})^2}{r_2^2} = \frac{1}{10} \quad \Rightarrow \quad r_2 = \sqrt{25.0\text{ m} \times 10} = 15.8\text{ m}$$

We find that you only need to be about 16 m away for the energy reaching your ear to be 10 times less. We roughly triple the distance from the source to get a reduction in energy of 10 times. Given $3^2 = 9$, our answer makes sense.

Wave power and wave intensity

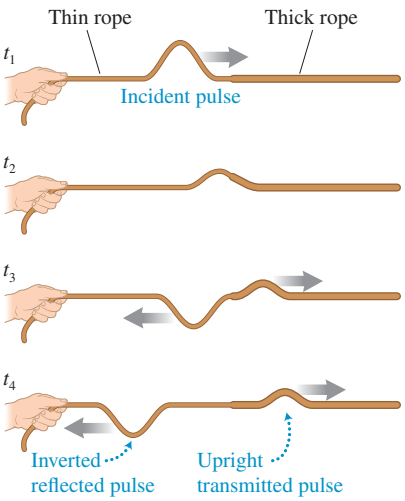
Earlier (in Chapter 7), we defined the power P of a process as energy change per unit time interval ($P = \Delta E/\Delta t$). Since this power is spread over the area the waves travel through, a more useful quantity for describing the wave is **intensity**. The intensity of a wave is defined as the energy per unit area per unit time interval that crosses perpendicular to an area in the medium through which it travels.

$$\text{Intensity} = \frac{\text{Energy}}{\text{time} \cdot \text{area}} = I = \frac{\Delta E}{\Delta t \cdot A} = \frac{P}{A} \tag{11.6}$$

The unit of intensity I is equivalent to joules per second per square meter ($\text{J/s} \cdot \text{m}^2$). Since J/s is a watt, the unit of intensity is then watts per square meter (W/m^2). The intensity of one-dimensional waves propagating without damping does not depend on the distance from the source.

REVIEW QUESTION 11.4 Is the following statement true? The energy of three-dimensional waves decreases by a factor of 4 and the amplitude decreases by a factor of 2 when the distance from the point source doubles. Explain your answer.

FIGURE 11.14 Snapshots of the reflection and transmission of a pulse at an interface (the wave is traveling from the thin rope to the thick rope).



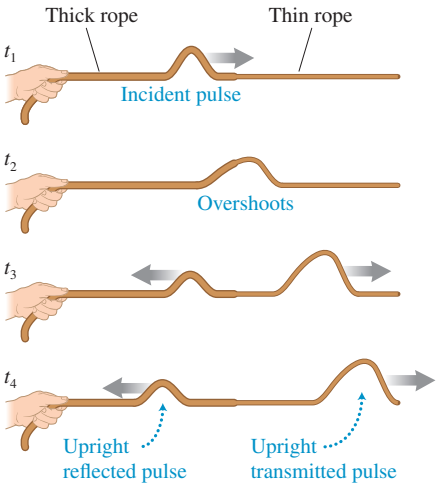


FIGURE 11.15 Snapshots of the reflection and transmission of a pulse at an interface (the wave is traveling from the thick rope to the thin rope).

11.5 Reflection and impedance

Until now, we have considered pulses and waves moving through a homogeneous medium, a medium with the same properties everywhere. What happens to a wave when there is an abrupt change from one medium to another? Figure 11.5a showed one such case—a pulse on a rope reflected off the end attached to a wall. The reflected pulse pointed down, opposite to the incident pulse. We say that the pulse was *inverted*. What other changes to the pulse can occur?

Imagine holding a thin rope (small mass per unit length) that is attached to a thicker rope (larger mass per unit length) on the right. You send an upright transverse pulse to the right in the thin rope (**Figure 11.14**). A partially reflected inverted pulse (oriented like the pulse reflected off the fixed end) returns to your hand, and a partially transmitted upright pulse of smaller amplitude travels in the thicker rope.

With the ropes connected in the opposite order (the thick rope on the left and thin rope on the right), you send an upright transverse pulse along the thick rope toward the right (**Figure 11.15**). Now, a partially reflected upright pulse returns to your hand, and a partially transmitted upright pulse of larger amplitude travels in the thin rope. Why?

In the first experiment (Figure 11.14), because of its larger mass per unit length, the right-hand thick rope is harder to accelerate upward than a thin rope would be. A small-amplitude upward pulse is initiated in the thick rope. Because the thick rope does not "give" as easily, it exerts a larger downward force than a thin rope would exert, starting an inverted reflected pulse back toward the left in the thin rope. The same happened in Figure 11.5a—we can think of a wall to which the rope is fixed (or your hand holding the rope) as an infinitely thick rope.

In the second experiment (Figure 11.15), when the upright pulse in the left-hand thick rope reaches the interface of the two ropes, the thin rope restrains the thick rope less than the thick rope restrains itself. The thick rope initiates a large upright transmitted pulse in the thin rope (which "gives" more easily because of its smaller mass per unit length). The thin rope overshoots its position relative to the thick rope and starts a small upright reflected pulse back in the thick rope. The extreme case of this happens when the pulse on a uniform rope reaches an end of the rope that is free to move (Figure 11.5b). When the pulse reaches the end of the rope, the rope overshoots and starts an upright reflected pulse.

Understanding the patterns that occur when waves travel from one medium to another allows us to better transmit information and protect ourselves from unwanted signals.

In the first experiment, a significant amount of the pulse energy traveled back from the thicker medium—thus less energy was transmitted forward. Similarly, your hard skull reflects most of the energy from sound waves traveling through the air. However, the structure of the ear is such that some of this energy can reach the inner ear and be detected.

The pattern of traveling waves in varying media also allows geologists to "see" under Earth's surface. Radio waves reflected from the bottom of the Antarctic ice sheet are characteristic of an ice-rock interface rather than an ice-water interface. Thus, geologists have determined that the ice sheet rests on rock rather than water. Geologists have also used the pattern of motion of seismic waves to determine that there is a sharp, distinctive boundary between the Earth's mantle and its outer core.

Impedance

A physical quantity called **impedance** characterizes the degree to which waves are reflected and transmitted at the boundary between different media. When a wave travels through a medium, parts of the medium move with respect to each other, or the medium gets distorted. The impedance Z of a medium is a measure of the difficulty a wave has in distorting the medium and depends on both the medium's elastic and inertial properties. The elastic property is related to the interactions between the particles in the medium (the stronger the interactions, the greater the impedance). The inertial property characterizes the density of the medium. Impedance is proportional to the product of the elastic and inertial properties of the medium.

If two media connected together at an interface have different elastic and inertial properties (for example, two different linear density ropes woven together), a wave traveling in one medium is partially reflected and partially transmitted at the boundary between the media. If the product of the elastic and inertial properties of the two media is the same, a wave moves from one medium to the other as if there is no change. If the impedances of two media are very different, most of the wave energy is reflected back into the first medium and does not travel into the second medium. One application of this effect is the use of **ultrasound** (a compression wave with frequencies higher than 20,000 Hz), which takes advantage of the differing densities of internal structures to "see" inside the body, for example, to determine the shape of a fetus inside the mother's uterus.

Ultrasound is poorly transmitted from air outside the body to tissue inside the body. The impedance of tissue is much greater than that of air. To overcome this problem, the area of the body to be scanned is covered with a gel that helps "match" the impedance between the emitter and the body surface. The emitter is then held directly against the gel-covered area. This matching allows the ultrasound wave to propagate into the body instead of being reflected off the body's surface.

Many animals can detect seismic signals. Elephants have stiff cartilage and dense fat in their feet, which matches the impedance of Earth's surface. Elephants at times lean forward on their front feet, seemingly to detect vibrations in the ground—for example, prior to approaching a water hole. Reports describe Asian elephants as vigorously responding to earthquakes, even trumpeting at the approach of an earthquake before humans feel the quake.

REVIEW QUESTION 11.5 Why is it impossible to create a traveling wave on a Slinky that propagates in only one direction?

11.6 Superposition principle and skills for analyzing wave processes

We have studied the behavior of a single wave traveling in a medium and initiated by a simple harmonic oscillator. Now we investigate what happens when two or more waves simultaneously pass through a medium.

FIGURE 11.16 The meeting of two pulses oriented (a) in opposite directions and (b) in the same direction.

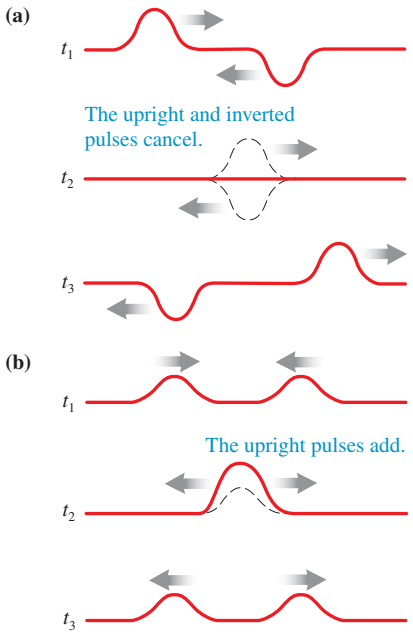

FIGURE 11.17 The superposition at point C of two waves that add.

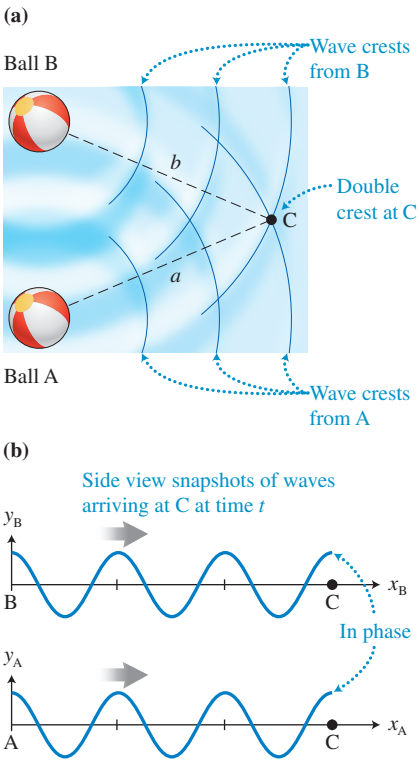

Figure 11.16a shows a string with an incident pulse traveling right and the reflected pulse (inverted) traveling left. When these pulses meet, the string looks undisturbed. Figure 11.16b shows the meeting of two upright pulses. The string bulges more than for each of them individually. In both cases, after meeting, both pulses continue traveling as if they never met. How can we explain these observations? In Figure 11.16a, the part of the string where the pulses met was pulled up by the pulse coming from the left and down by the pulse coming from the right, causing a zero net disturbance. In Figure 11.16b, the part of the string where the pulses met is pulled up by both the right- and left-moving pulses, resulting in a double-amplitude disturbance. We can hypothesize that when pulses meet, the resultant disturbance is the sum of the two (pulse orientation is important), as if each pulse pulls the rope separately.

The final displacement of the rope at a particular time and location is just a combination of the two pulses at that time and location—adding them together:

$$y_{\text{net}} = y_1 + y_2 + \cdots \tag{11.7}$$

This looks similar to the other kind of superposition we've encountered before—the superposition of forces. We can test this superposition idea by using it to predict the outcomes of new experiments.

Imagine we have two vibrating sources in water—for example, you push beach balls A and B up and down in exactly the same way. (**Figure 11.17a**). The sources A and B vibrate with the same amplitude and period, each sending a wave toward point C. The source A wave will cause C to vibrate as

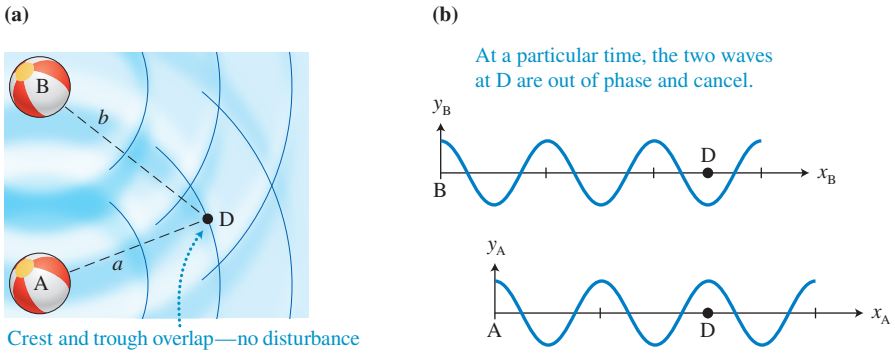
$$y_{\text{A}} = A_{\text{C}} \cos\left[\frac{2\pi}{T}\left(t - \frac{a}{v}\right)\right]$$

The source B wave will cause C to vibrate as

$$y_{\text{B}} = A_{\text{C}} \cos\left[\frac{2\pi}{T}\left(t - \frac{b}{v}\right)\right]$$

where A_{C} is the amplitude at location C (smaller than the initial).

If distances a and b are equal, then the two vibrations arrive in the same phase at point C:



$$2\pi\frac{a}{Tv} = 2\pi\frac{b}{Tv}$$

If one wave causes C to move up, the other one will also cause it to move up (the displacements from the A and B waves at C are shown in Figure 11.17b). *If* the idea of superposition is correct *and* point C is at the same distance from both sources, *then* the amplitude of vibration at C will be twice the amplitude caused by one wave source at the same location. There are many points at the same distance from both sources, and the vibrations at these points will have twice the amplitude caused by one wave.

More generally, the superposition principle predicts a similar effect for any point where the difference in distance from source A and from source B is an integer multiple of the wavelength (if $a - b = n\lambda$ for $n = 0, \pm 1, \pm 2, \ldots$). At any of these points, the resultant vibration amplitude due to both waves will be the sum of the amplitudes of the individual waves.

Suppose now that we choose a point D located so that the wave from A arrives there with a maximum positive displacement and the wave from B arrives with a maximum negative displacement (see **Figure 11.18a**). Then the A wave pushes point D up while the B wave pushes it down the same distance. The net displacement is almost zero. This situation happens only if one wave has to travel a distance that is one-half, or three-halves, or five-halves, etc. times the wavelength λ longer than the other and we can neglect the difference in the amplitudes of the two waves due to a small difference in the distances that they travel to location D (Figure 11.18b). We conclude that at locations where $a - b = (n + 1/2)\lambda$ for $n = 0, \pm 1, \pm 2, \ldots$, there will be little vibration because the two waves will nearly cancel each other.

FIGURE 11.18 The superposition at point D of two waves that cancel.

Let us see whether this actually happens. Take two speakers at different locations and predict places between them where our ears will hear little sound. Then put your head in the predicted locations and check! The example below shows you how to make these predictions.

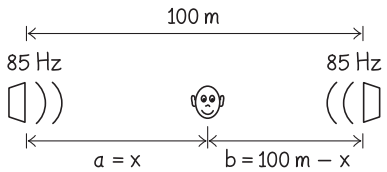
PROBLEM-SOLVING STRATEGY 11.1 Analyzing wave processes

Sketch and translate

- Sketch the situation. Label all known quantities.
- Label the unknown quantities.

Simplify and diagram

- Decide what simplifying assumptions you should make.
- Draw displacement-versus-time or displacement-versus-position graphs to represent the waves if necessary.



Represent mathematically

- Represent the problem using mathematical relationships between physical quantities.

EXAMPLE 11.4 **Where is there no sound?**

Two sound speakers separated by 100 m face each other and vibrate in unison at a frequency of 85 Hz. Determine three places on a line between the speakers where you cannot hear any sound.

If x is your distance from the left speaker, we can write the distances the sound travels from the left and right speakers to you, a and b, respectively, in terms of x.

Assume that the amplitudes of the waves are equal when they pass through the point of interest. Assume that both of your ears are located at the same point. We have two waves of the same frequency passing through the same locations. We can use the superposition principle to find the locations of destructive interference. You should hear no sound at places where the distance from the left speaker is an odd multiple of a half wavelength farther than the distance from the right speaker. The displacement-versus-position graph for this situation is shown in Figure 11.18b.

You should hear no sound if

$$a - b = \left(n + \frac{1}{2}\right)\lambda \text{ for } n = 0, 1, 2, \ldots$$

Here a is x and b is 100 m $-$ x: $x - (100\text{ m} - x) = \frac{\lambda}{2}, \frac{3\lambda}{2}, \frac{5\lambda}{2} \ldots$,

where $\lambda = \frac{v_{\text{sound}}}{f} = \frac{340\text{ m/s}}{85\text{ Hz}} = \frac{340\text{ m/s}}{85\text{ s}^{-1}} = 4.0\text{ m}.$

(CONTINUED)

Solve and evaluate

- Solve the equations for the unknown quantity.
- Evaluate whether the results are reasonable (the magnitude of the answer, its units, how the solution behaves in limiting cases, and so forth).

Solve the equation in the last step for places where we hear no sound:

$$x - (100\text{ m} - x) = \frac{\lambda}{2}, \frac{3\lambda}{2}, \frac{5\lambda}{2} \ldots$$
$$\Rightarrow 2x - 100\text{ m} = \frac{\lambda}{2}, \frac{3\lambda}{2}, \frac{5\lambda}{2} \ldots$$
$$\Rightarrow 2x = 100\text{ m} + \frac{\lambda}{2}, \frac{3\lambda}{2}, \frac{5\lambda}{2} \ldots$$
$$\Rightarrow x = \left[50\text{ m} + \frac{\lambda}{4}\right], \left[50\text{ m} + \frac{3\lambda}{4}\right], \left[50\text{ m} + \frac{5\lambda}{4}\right] \ldots$$

Using $\lambda = 4.0$ m, we expect no sound at

$$x = 51\text{ m}, 53\text{ m}, 55\text{ m}, \ldots$$

Note that the first place is 51 m from the left speaker and 49 m from the right (one half wavelength different). The next place is 53 m − 47 m = 6 m or 1.5 wavelengths. The answers seem reasonable. The distance between the points with no sound is much larger than the size of your head, so the assumption of your two ears being at the same location is justified. When we conduct the experiment we find that at the predicted locations we hear almost no sound.

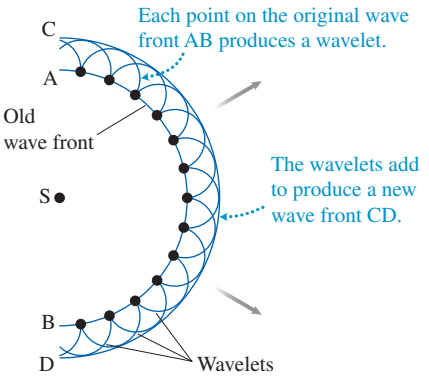
Try it yourself For the situation described in this example, where should you stand to hear sound with twice the amplitude?

Answer The condition for these places is that the distances from the ear to each source should differ by an integer multiple (including zero) of the wavelength of the waves: $x - (100\text{ m} - x) = 0, \lambda, 2\lambda, \ldots$. This condition is satisfied at positions 50 m, 52 m, 54 m, ...

We can now assert the superposition principle for waves with greater confidence.

Superposition principle for waves When multiple waves pass through the same medium at the same time, the net displacement at a particular time and location in the medium is the sum of the displacements that would be caused by each wave if it were alone in the medium at that time. Mathematically, this statement can be written as

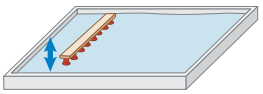
$$y_{\text{net}} = y_1 + y_2 + \cdots \tag{11.7}$$

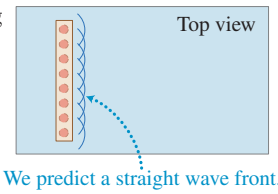


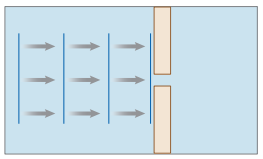
The phenomenon that occurs when two or more waves are present at the same location at the same time is called **interference**. If the waves have the same frequency, the resulting pattern is stable in time. The points where the amplitude of the resultant wave is large are points of **constructive interference** (point C in Figure 11.17); the points where the waves add to produce a smaller amplitude are called points of **destructive interference** (point D in Figure 11.18).

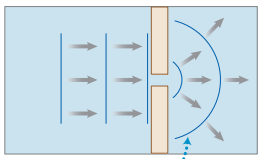
What happens to the energy of the waves when they meet? When the interference pattern is stable in time, the energy gets redistributed in space—more energy goes into the points of constructive interference and none to the points of destructive interference. However, these are extreme cases. At most points, the interference is neither completely destructive nor completely constructive.

Huygens' principle









When a beach ball bobs up and down in water, circular waves move outward. We can explain the formation of the waves using the superposition principle, first explained this way by Christiaan Huygens (1629–1695). It begins with a wave front represented by curved line AB moving at speed v away from a point source S (**Figure 11.19**). To determine the location of the wave front a short time interval Δt later, draw a large number of circular arcs, each centered on a different point of wave front AB. Each arc represents a **wavelet** that moves away from a point on the original wave front. The addition of these wavelets produces a new wave front whose shape can be determined by adding the disturbances due to all wavelets. The new wave front is determined by drawing a tangent to the front edges of the wavelets—the curved line CD in Figure 11.19. To test Huygens' idea, consider two new experiments in Testing Experiment **Table 11.3**.

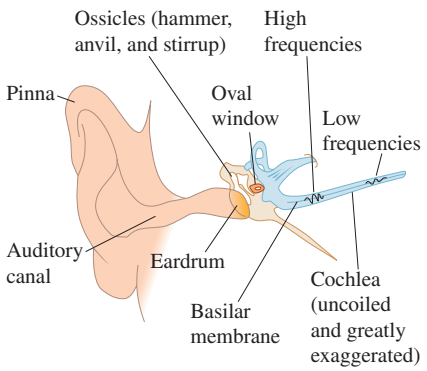
FIGURE 11.19 Using Huygens' principle to create a new wave front.

TESTING EXPERIMENT TABLE 11.3 **Testing Huygens' principle**

VIDEO TET 11.3

Testing experiment	Prediction	Outcome
Take a strip of cardboard with many closely spaced pushpins pushed through it from the bottom in a line. Place the cardboard in a tray filled with water just above the water so that when it vibrates, the pins move up and down, each creating a wavelet in the water. Then shake the cardboard to produce vibrations of the pins in the water. 	When the resulting circular wavelets are added, they should produce a straight wave front.  We predict a straight wave front.	We observe the predicted straight wave front.
Remove the pins from the cardboard and shake it. When the cardboard vibrates in the tray of water, it creates a wave with wave fronts that look like lines (plane waves). Place a barrier with a narrow slit opening in the path of the plane waves. 	The vibrations of water beyond the narrow slit should be circular wavelets.  We predict circular wavelets.	We observe circular wavelets spreading beyond the narrow slit.

Conclusion



Predictions based on Huygens' principle match the outcomes of the testing experiments. These experiments do not disprove the principle but rather give us more confidence in it.

REVIEW QUESTION 11.6 Your friend says that it is impossible for two waves to arrive at the same point and still have no vibrational motion at this point. How can you convince him that this is possible?

11.7 Sound

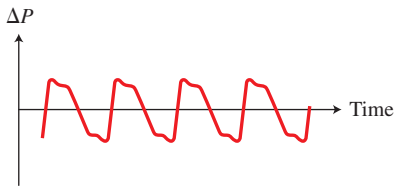
We hear sound when compressions and decompressions of air at the eardrum cause it to vibrate (**Figure 11.20**). Amplification mechanisms in the outer ear and middle ear increase the vibrations up to a factor of 180 and transform them into vibrations in the fluid inside the inner ear. Nerve cells in the inner ear can distinguish sounds differing by just 3 Hz over a range of approximately 20 Hz to 20,000 Hz. Compression waves in this frequency range are called **sound**. Higher and lower frequency waves are called **ultrasound** and **infrasound**, respectively. Many animals, such as bats, dolphins, whales, dogs, and some fish, can sense ultrasonic or infrasonic frequencies.

FIGURE 11.20 A simplified sketch of the human ear.

Pressure waves

When physicists describe sound waves mathematically, they use a new physical quantity, *pressure* (P), that is equal to the magnitude of the perpendicular component of the force $F_\perp$ that a gas, liquid, or solid exerts on a surface divided by the contact area A over which that force is exerted:

$$P = \frac{F_\perp}{A}$$



The units of pressure are $\mathrm{N/m^2}$. The air surrounding us in normal conditions exerts about 10^5 N per every square meter of surface; thus normal atmospheric pressure is $P_{\mathrm{Atm}} = 10^5\,\mathrm{N/m^2}$. We will learn more about pressure in Chapter 12.

The compressions and decompressions of air that we hear as sound are described by the variations of air pressure relative to the normal pressure when no sound is present (**Figure 11.21**). A young person with healthy hearing can hear sound that corresponds to only $10^{-5}\,\mathrm{N/m^2}$ variation of pressure, which is less than one-billionth of atmospheric pressure. This pressure variation is equivalent to the force that Earth exerts on one ant distributed over the area of one square meter. We are amazingly sensitive creatures!

Humans perceive the amplitude of pressure variations in sound waves as the *loudness* of sound. However, it is not only the amplitude of the waves that affects how loud a sound "feels" for us. Our sensitivity to different frequencies of sound waves also affects how loud we perceive a sound to be. Humans are most sensitive to frequencies around 4000 Hz and least sensitive to sounds of 20 Hz and 20,000 Hz. This means that humans do not perceive equal-amplitude sounds of different frequency as equally loud. As a result, loudness is not a physical quantity. It is a person's subjective impression of the intensity of sound. Instruments that inform us about the loudness of a sound do not measure the sound's pressure amplitude but instead measure its intensity.

TIP Although they have the same symbol P, do not confuse the ideas of pressure and power: use the context to decide which concept is being used. Similarly, A is used for both area and amplitude.

FIGURE 11.21 A pressure-versus-time graph of sound from one piano note.

QUANTITATIVE EXERCISE 11.5 **Sound energy at a construction site**

The intensity of sound at a construction site is $0.10\,\mathrm{W/m^2}$. If the area of the eardrum is $0.20\,\mathrm{cm^2}$, how much sound energy is absorbed by one ear in an 8-h workday?

Represent mathematically The intensity I of the sound, the area A of the eardrum, and the time interval Δt of the exposure have been given. We wish to determine the sound energy ΔE absorbed by the ear. Equation (11.6) relates all of these quantities:

$$\text{Intensity} = I = \frac{\text{Energy}}{\text{time} \cdot \text{area}} = \frac{\Delta E}{\Delta t \cdot A}$$

To find the energy, multiply both sides by the time interval and the area:

$$\Delta E = I \cdot \Delta t \cdot A$$

Solve and evaluate In using the above, we need to convert the time interval into seconds and the area into $\mathrm{m^2}$.

$$\Delta E = (0.10\,\mathrm{W/m^2})\left[(8.0\,\mathrm{h})\left(\frac{3600\,\mathrm{s}}{1\,\mathrm{h}}\right)\right] \times \left[(0.20\,\mathrm{cm^2})\left(\frac{10^{-4}\,\mathrm{m^2}}{1\,\mathrm{cm^2}}\right)\right] = 0.058\,\mathrm{J}$$

This looks like a small number. However, our perception of sound energy depends on the power per unit area, not the total energy. Our environment includes sounds that differ in intensity from about $10^{-12}\,\mathrm{W/m^2}$ (barely audible) to nearly $1\,\mathrm{W/m^2}$ (a painful sound). The sound intensity in a typical classroom is about $10^{-7}\,\mathrm{W/m^2}$.

Try it yourself How would the answer differ for a child with an eardrum that is half the area?

Answer The sound energy would be half as big.

Intensity level

Because of the wide variation in the range of sound intensities, a quantity called **intensity level** is commonly used to compare the intensity of one sound to the intensity of a reference sound. Intensity level is defined on a base 10 logarithmic[1] scale as follows:

$$\beta = 10 \log_{10} \frac{I}{I_0} \tag{11.8}$$

where I_0 is a reference intensity to which other intensities I are compared (for sound, $I_0 = 10^{-12}\,\mathrm{W/m^2}$, the smallest sound intensity typically detectable by humans).

[1] If $x = b^y$, then $y = \log_b(x)$. For common logarithms $b = 10$. Thus for $y = \log(x)$, $x = 10^y$.

I and I_0 in Eq. (11.8) have the same units, and the intensity level is a dimensionless quantity. Intensity level does have a dimensionless unit associated with it, called the decibel (dB). An increase of 10 dB is equivalent to a 10-fold increase in intensity. The unit serves as a reminder of what we are quantifying, much like the radian is a dimensionless reminder of one way of quantifying angles. The intensity levels β of several familiar sounds are listed in **Table 11.4**.

TABLE 11.4 Intensities and intensity levels of common sounds

Source of sound	Intensity (W/m^2)	Intensity level (dB)	Description
Large rocket engine (nearby)	10^6	180	
Jet takeoff (nearby)	10^3	150	
Rock concert with amplifiers (2 m); jet takeoff (60 m)	1	120	Pain threshold
Heavy truck (15 m)	10^{-3}	90	Constant exposure endangers hearing
Niagara Falls (nearby)	10^{-3}	90	
Inside an average factory	10^{-4}	80	
Busy traffic	10^{-5}	70	
Normal conversation (1 m)	10^{-6}	60	
Quiet office	10^{-7}	50	Quiet
Rustling leaves	10^{-10}	20	Barely audible
Normal breathing	10^{-11}	10	
	10^{-12}	0	Hearing threshold

QUANTITATIVE EXERCISE 11.6 **Busy classroom**

The sound in a classroom has an intensity of $10^{-7}\ W/m^2$. (a) Determine the intensity level of that sound. (b) If the sound intensity doubles, what is the new sound intensity level?

Represent mathematically To calculate the intensity level β, we need to compare the given sound intensity I with the reference intensity for sound $I_0 = 10^{-12}\ W/m^2$ and then take 10 times the log of that ratio (see Appendix A for more information on logarithms):

$$\beta = 10 \log\left(\frac{I}{I_0}\right)$$

Solve and evaluate (a) The ratio of the sound intensity I and the reference intensity I_0 is

$$\frac{I}{I_0} = \frac{10^{-7}\ W/m^2}{10^{-12}\ W/m^2} = 10^5$$

Since $\log 10^5$ is 5, the sound intensity level is

$$\beta = 10 \log 10^5 = 10(5) = 50\ dB$$

The classroom is pretty quiet. Maybe the students are taking a test? (b) If I is doubled, the ratio of I and I_0 becomes

$$\frac{I}{I_0} = \frac{2 \times 10^{-7}\ W/m^2}{10^{-12}\ W/m^2} = 2 \times 10^5$$

The sound intensity level is then

$$\beta = 10 \log(2 \times 10^5) = 10(5.3) = 53\ dB$$

A doubling of intensity corresponds to an intensity level increase of just 3 dB.

Try it yourself The sound intensity at a concert is $0.10\ J/s \cdot m^2$. What is the intensity level?

Answer 110 dB.

Pitch, frequency, and complex sounds

Another perceived physiological characteristic of sound is *pitch*. It has no units, but we all know what the terms high and low pitch mean. Pitch relates to our perception of the frequency of sound—a higher pitch means a sound of higher frequency.

FIGURE 11.22 Pressure-versus-time graphs produced by one or two tuning forks.

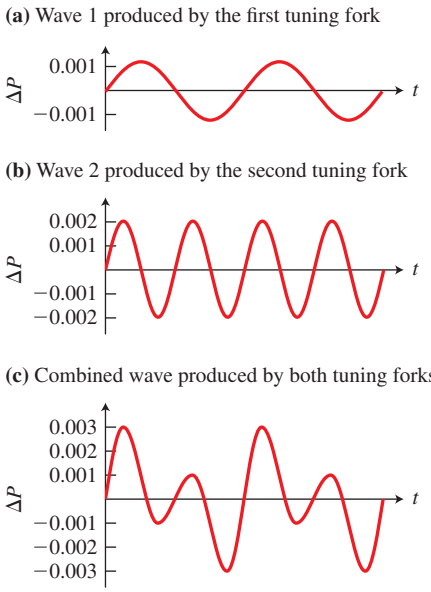


FIGURE 11.23 A frequency spectrum produced by two tuning forks.

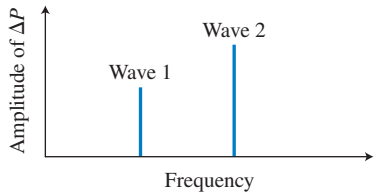

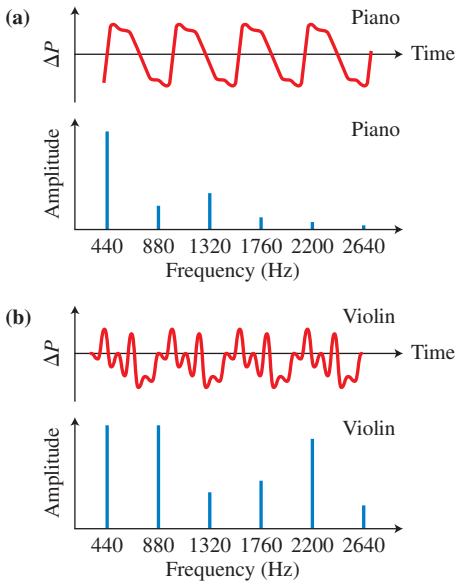

FIGURE 11.24 Waveforms and frequency spectra for a piano and a violin playing concert A.

However, there is more to sound than the sensations of its loudness and pitch. For example, an oboe and a violin playing the note concert A equally loudly at 440 Hz sound very different. Sound must have some other property that causes these different sensations in our ears. Let's use a microphone and a computer to look at a pressure-versus-time graph of a sound wave produced by playing one note on a piano. Notice that the graph in Figure 11.21 has negative values; thus it must be representing the pressure difference from atmospheric pressure. There is a characteristic frequency, but the wave is not sinusoidal. What causes this different shape?

To answer this question, we use two tuning forks with the second fork vibrating at twice the frequency of the first. Each fork separately produces a sinusoidal wave (**Figures 11.22a** and b). When we hit the two forks simultaneously, the wave looks different (Figure 11.22c)—it is more like that recorded when playing the piano. It must be a superposition of the waves from the two tuning forks. This complex pattern is called a **waveform**—a combination of two or more waves of different frequencies and possibly different amplitudes.

It is possible, using a microphone and a device known as a spectrum analyzer, to decompose a complex waveform into its component frequencies. The amplitude of each component can be plotted versus the frequency of that component, a graph called the **frequency spectrum** of the waveform. A frequency spectrum of the waveform in Figure 11.22c is shown in **Figure 11.23**. The height of the line at each frequency is proportional to the amplitude of the wave at that frequency. In this case, the graph shows that the amplitude and frequency of wave 2 are greater than those of wave 1.

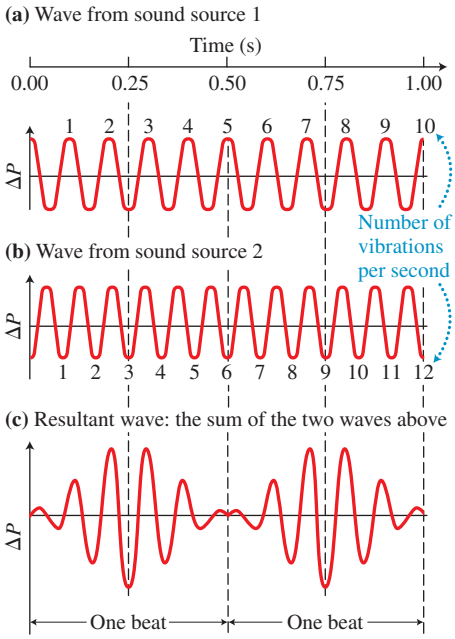
Most sounds we hear are complex waves consisting of sinusoidal waves of many different frequencies. "White noise"—the sound you hear if you tune a radio to a frequency that doesn't match a nearby radio station—includes waves of a broad range of frequencies. We seldom associate a pitch with white noise. However, if the complex sound is the result of the addition of a relatively large-amplitude lowest frequency component (called the **fundamental**) with several higher frequency components that are whole-number multiples of the fundamental (called **harmonics**), then we usually identify the pitch of the sound as being that of the fundamental frequency. The waveforms and frequency spectra of complex waves from a piano and a violin while playing concert A at 440 Hz are shown in **Figure 11.24**. Notice that the violin A has many frequency components, which are all multiples of 440 Hz (880 Hz, 1320 Hz, 1760 Hz, 2200 Hz, and even higher frequencies). Different musical instruments have different frequency spectrums that contribute in part to the quality of the sound we associate with that instrument.

Beat and beat frequencies

What happens when two sound waves of close but not identical frequencies are present at the same time at the same location? Suppose that two sound sources are equidistant from a microphone that records the air pressure variations due to the two sound sources as a function of time (**Figure 11.25**). Source 1 vibrates at 10 Hz and source 2 vibrates at 12 Hz. Figures 11.25a and b show the pressure variations due to wave 1 and wave 2 during a 1.0-s interval. Note that in each case only one wave source is playing at a time. Consider the pressure-versus-time wave pattern we would get if both sound sources played at the same time.

We add the two waves shown in Figures 11.25a and b to see the pattern produced when both sounds play simultaneously (Figure 11.25c). Note in Figure 11.25 that at time 0.00 s the positive pressure caused by wave 1 cancels the negative pressure caused by wave 2. The net disturbance at time 0.00 s is zero and there is no sound. At 0.25 s, both waves have a maximum negative pressure variation, so the net disturbance is twice that of a single wave—the sound is loud. At 0.50 s, the two wave pressure variations again cancel each other, causing a zero pressure disturbance and no sound.

The pattern resulting from adding two waves of close frequencies shown in Figure 11.25c from 0.00 s to 0.50 s is called a **beat**. The vibration has a frequency of 11 Hz (the average of the two wave frequencies), but its amplitude is modulated from zero to approximately twice the normal amplitude and back to zero again at 0.50 s. A second beat is produced from 0.50 s to 1.00 s. The **beat frequency** is the number of beats per second—in this case, 2 beats/s—the sound goes on and off twice each second. The beat frequency is just the difference in the two wave frequencies: 12 Hz − 10 Hz = 2 Hz. This modulated vibration frequency is easily heard if the beat frequency is a few hertz or less.



Beats and beat frequency A beat is a wave that results from the superposition of two waves of about the same frequency. The beat (the net wave) has a frequency equal to the average of the two frequencies and has variable amplitude. The frequency with which the amplitude of the net wave changes is called the beat frequency f_{beat}; it equals the difference in the frequencies of the two waves:

$$f_{beat} = |f_1 - f_2| \tag{11.9}$$

Beats are useful in precise frequency measurements. For example, a piano tuner can easily set the frequency of the middle C string on the piano to 262 Hz by listening to the beat frequency produced when the piano string and a 262-Hz tuning fork are sounded simultaneously. If the tuner hears a beat frequency of 3 Hz, then the piano string must be vibrating at either 259 Hz or 265 Hz—a difference of 3 Hz from the frequency of the tuning fork. The string is then tightened to increase the string frequency or loosened to lower the frequency until the beat frequency is reduced to zero (you do not hear beats anymore); then the string is vibrating at exactly 262 Hz.

REVIEW QUESTION 11.7 Is the following sentence true? When two sinusoidal sounds of the same amplitude but different frequencies are added, the result is not a sinusoidal wave. Explain your answer.

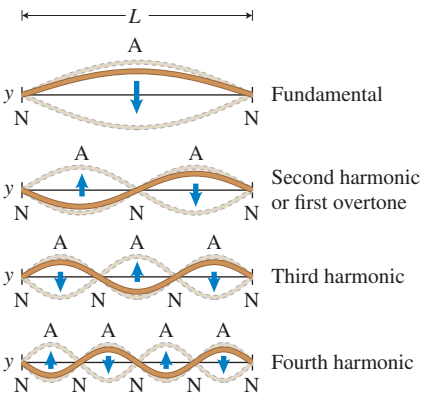


FIGURE 11.25 Beats.

11.8 Standing waves on strings

The superposition of waves is the basis for understanding how musical instruments produce sound. Let's consider stringed instruments first. Start by observing the vibration of a rope with one end attached to a fixed support (a wall) while you hold the other end your hand. You shake that end up and down. Depending on the frequency with which you shake your hand, the rope has either very small amplitude irregular vibrations or large-amplitude sine-shaped vibrations. The latter appear not to be traveling waves but are instead coordinated vibrations, with parts of the rope vibrating up and down with large amplitude and other parts not vibrating at all. Such waves are called **standing waves**. Displacement-versus-position graphs for several of those waves for one instant are shown in **Figure 11.26**. Because stringed musical instruments have both ends of their strings fixed, the motion of the strings forms standing waves. How is the first standing wave vibration in Figure 11.26 produced? We will explore this question in Observational Experiment **Table 11.5**, on the next page.

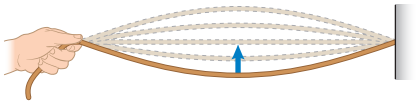

FIGURE 11.26 Standing waves on a string.
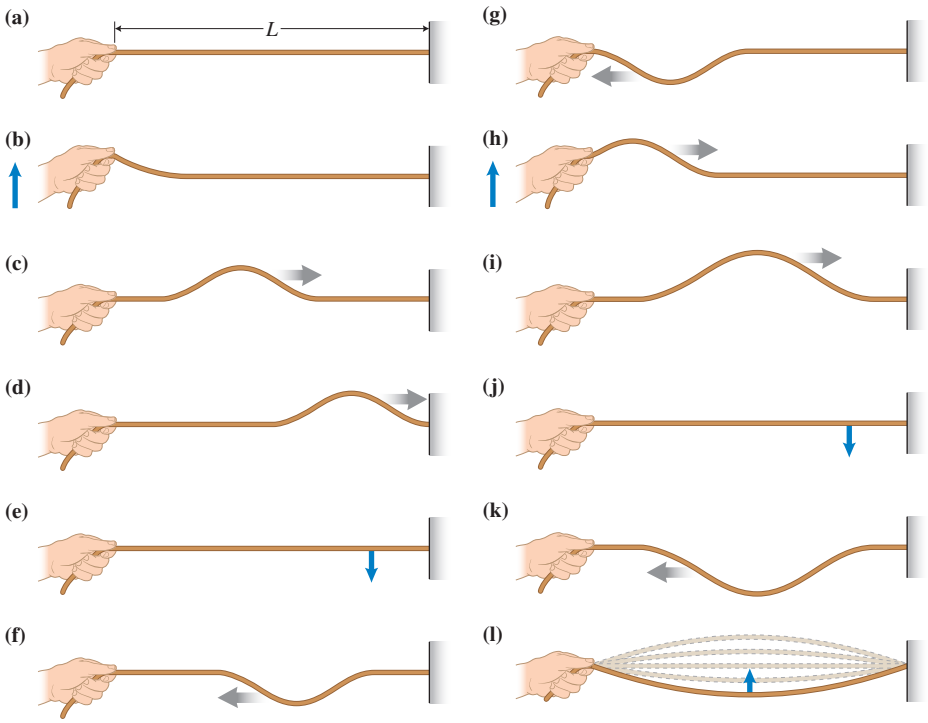
The rope vibrates between the dashed lines.



OBSERVATIONAL EXPERIMENT TABLE 11.5 Producing the first standing wave vibration

VIDEO OET 11.5

Observational experiment	Analysis
You shake a rope that is fixed at one end at a relatively low frequency, and at one particular frequency you observe the large-amplitude vibration.	A pulse starts moving to the right (b–d). When it reaches the fixed end, the upward pulse is reflected and inverted to a downward pulse traveling back toward your hand (e–g). When it reaches your hand, it once again reflects and inverts to an upward pulse (h). To make this pulse bigger, you begin another upward shake, timing the shake so that it adds to the previous upward pulse that has just been reflected (h).

Pattern

- You must shake the rope upward each time a previous pulse returns. The amplitude of the disturbance traveling along the rope grows.
- You need one up and down shake during the time interval $(2L/v)$ that it takes for the pulse to travel down the string and back. Thus the period of the one vibration is $T_1 = \dfrac{2L}{v}$, and consequently the wave frequency is

$$f_1 = \frac{1 \text{ vibration}}{\dfrac{2L}{v}} = \frac{v}{2L}$$

The subscript 1 in the last equation in Table 11.5 means the lowest standing wave frequency. The numerator in that equation is the number of vibrations, but *vibration* is not a unit (similar to the radian and the decibel). Thus, this lowest frequency vibration of the rope is one up and down shake per time interval $\tau = 2L/v$, or

$$f_1 = \frac{1}{\tau} = \frac{1}{\dfrac{2L}{v}} = \frac{v}{2L} \tag{11.10}$$

This frequency is called the **fundamental frequency**. If the shaking frequency is just a little greater or a little less than this, each new pulse will interfere destructively with previous pulses, and there will no longer be a time-independent pattern; the standing wave will disappear and multiple traveling waves will bump here and there, like splashing

water. At frequency $f_1 = v/(2L)$, each new pulse constructively interferes with previous pulses and creates a large-amplitude vibration. The wavelength of this fundamental frequency vibration is

$$\lambda_1 = \frac{v}{f_1} = \frac{v}{\frac{v}{2L}} = 2L$$

The length of the rope equals one-half of the wavelength of the wave that has this fundamental frequency. We will test these ideas in the following experiment.

A banjo's D string has a mass of 0.252 g and length 0.690 m. The wooden peg pulls on its end, exerting a 60.0-N force. Can we predict the frequency of its fundamental vibration? We can find the speed of the wave on the string using Eq. (11.5):

$$v = \left[\frac{F_{\text{Peg on String}}}{(m_{\text{String}}/L_{\text{String}})}\right]^{1/2} = \left[\frac{(60.0\ \text{N})}{(0.252 \times 10^{-3}\ \text{kg})/(0.690\ \text{m})}\right]^{1/2} = 405\ \text{m/s}$$

Then we can use this speed to predict the fundamental frequency:

$$f_1 = \frac{v}{2L} = \frac{405\ \text{m/s}}{2(0.690\ \text{m})} = 294\ \text{s}^{-1} = 294\ \text{Hz}$$

When we pluck a banjo D string and compare it to the frequency of different tuning forks, we find that the matching fork has the frequency $f = 294$ Hz. The agreement is excellent!

Now consider how the second harmonic can be produced (Figure 11.26). You vibrate the rope so that your hand has two up and down shakes during the time interval that is needed for a pulse to make a round trip down the rope and back (**Figure 11.27**). The new pulse adds to a pulse started earlier that has completed a round trip back to your hand. Thus, the frequency f_2 of the second harmonic:

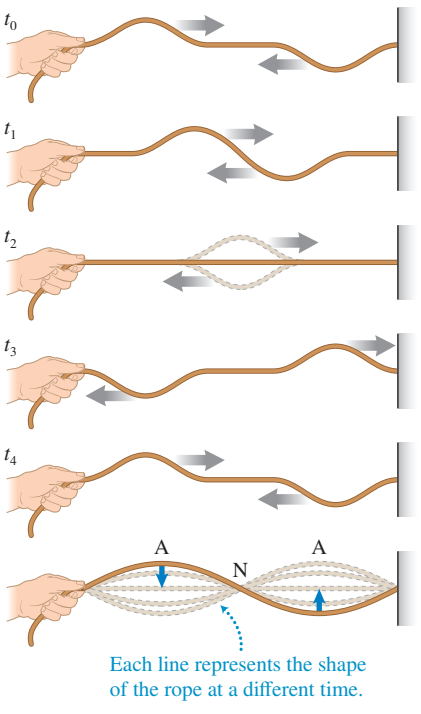
$$f_2 = \frac{2\ \text{vibrations}}{\frac{2L}{v}} = 2\frac{v}{2L}$$

We can see a pattern now.

Standing wave frequencies on a string The frequencies f_n at which a string with fixed ends can vibrate are

$$f_n = n\left(\frac{v}{2L}\right) \text{ for } n = 1, 2, 3, \ldots \qquad (11.11)$$

where v is the speed of the wave on the string and L is the string length.



Since $\lambda = v/f$, we can write an expression for the wavelengths of these allowed standing wave vibrations:

$$\lambda_n = \frac{v}{f_n} = \frac{v}{n\left(\frac{v}{2L}\right)} = \frac{2L}{n} \text{ for } n = 1, 2, 3, \ldots \qquad (11.12)$$

Note that a rope or string will vibrate with large amplitude only at those frequencies for which a pulse produced by the wave source (for example, the vibrating hand) is reinforced by a new pulse after completing a round trip up the string and back again. Thus standing waves are caused by the superposition of waves moving in opposite directions.

How are standing waves different from traveling waves? When a traveling wave moves along the string, each point on the string vibrates between the maximum and minimum displacements (between $y = \pm A$). However, different points reach the maximum displacements at different times (the phase of the wave is different at different

FIGURE 11.27 Producing the second harmonic on a string or rope.

locations). In a standing wave, only very specific points on the string, called **antinodes** (labeled A in Figure 11.27), reach the maximum displacement. Other points, called **nodes** (labeled N in Figure 11.27), do not vibrate at all. However, each point reaches its respective maximum displacement at the same time—the points vibrate in phase. When you play a musical instrument, you excite multiple standing wave vibrations. For example, when you bow a violin string, you simultaneously excite 10 or 20 standing wave vibrations.

EXAMPLE 11.7 **Playing a banjo**

A banjo D string is 0.69 m long and has a fundamental frequency of 294 Hz. Shortening the string (by holding the string down over a fret) causes it to vibrate at a higher fundamental frequency. Where should you press to play the note F-sharp, which has a fundamental frequency of 370 Hz?

Sketch and translate We know that when the length of the string is $L = 0.69$ m, the fundamental frequency is $f_1 = 294$ Hz. At what length of the string L' is the fundamental frequency $f_1' = 370$ Hz?

Simplify and diagram Assume that the speed of the wave on the string is independent of where the finger pushes down on the string.

Represent mathematically The fundamental frequency f_1 relates to the string length L by the equation $f_1 = v/(2L)$, or $L = v/(2f_1)$. We cannot solve immediately for the unknown length when the string is vibrating at 370 Hz since we do not know the speed v of the wave on the string. But we can use this idea to write an expression for the speed of the wave for both cases (the speed is the same for both cases):

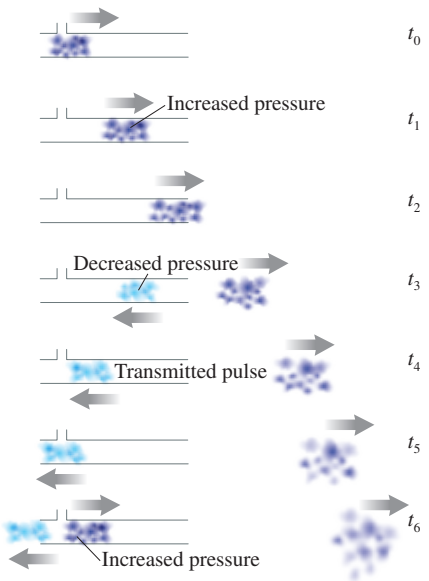
$$v = f_1(2L) = f_1'(2L')$$

Solve and evaluate Dividing both sides of the expression for the speed by f_1' and by 2, we get an expression for L':

$$L' = \frac{f_1 L}{f_1'} = \left(\frac{f_1}{f_1'}\right)L = \left(\frac{294\text{ Hz}}{370\text{ Hz}}\right)(0.69\text{ m}) = 0.55\text{ m}$$

The answer is reasonable, as it is less than 0.69 m. To find where to press on the string, we need to find the difference between the original length L and the new length L':

$$L - L' = 0.69\text{ m} - 0.55\text{ m} = 0.14\text{ m}$$



You should press 0.14 m from the end of the string.

Try it yourself If tuned correctly, the fundamental frequency of the A string of a violin is 440 Hz. List the frequencies of several other standing wave vibrations of the A string.

Answer The other standing wave frequencies are whole-number multiples of the fundamental: 880 Hz, 1320 Hz, 1760 Hz, and so forth.

REVIEW QUESTION 11.8 One end of a horizontal string of length L passes over a pulley with a block hanging at the end. A motor attached to the other end of the string exerts a constant horizontal force on the string. When the motor is turned on, it vibrates the end of the string up and down at frequencies that increase slowly from zero to a high frequency. What do you observe?

FIGURE 11.28 Producing a standing wave vibration in an open-open pipe.

11.9 Standing waves in air columns

Take a bottle, partially fill it with water, and blow across the top of the bottle. You hear sound with a pitch that depends on the amount of water in the bottle. The same phenomenon underlies how sound is made in musical instruments made of pipes or tubes, such as organs, clarinets, and flutes. How can we explain this phenomenon?

Standing waves in open-open pipes

A flute is a wind instrument that is an example of an **open-open** pipe, so called because it is open on both ends. Blowing into the open-open pipe initiates pressure pulses at that end of it. Alternating increased and decreased pressure pulses move down the air column, compressing the air in the instrument in a repetitive fashion (**Figure 11.28**, $t_0 \rightarrow t_2$). Near the opposite end, the flute is also open at the nearest open valve. The high-pressure pulse expands into open space outside of the valve, leaving behind a pulse of decreased pressure that reflects back into the tube.

This change from high to low pressure is similar to the phase change of a pulse on a string reflected off a fixed end. This phase change does not occur when a pressure pulse reaches a closed end.

The pulse of decreased pressure moves back toward the other end of the pipe where it started ($t_3 \rightarrow t_5$) and is reflected at the open end on the left (t_6). The higher pressure outside the pipe causes the decreased pressure pulse to compress as air rushes in, becoming a high-pressure pulse. If a new high-pressure pulse is initiated at this time, it interferes constructively with the reflected pulse, and its amplitude increases. If this is done repeatedly, a large-amplitude standing wave vibration builds up in the open-open pipe. If, however, the new air pressure pulse is too early or too late, it interferes destructively with the reflected pulse, and the amplitude decreases.

The frequency of standing wave vibrations in pipes depends on the time interval needed for a pulse to travel down the pipe and back again. If the sound pulse travels at a speed v along a pipe of length L, then the time interval T needed to travel a distance $2L$ is $T = 2L/v$. To reinforce the vibration of air in the pipe, and to create a standing wave of fundamental frequency, pressure pulses should occur once each time period T, or at a frequency $f = 1/T = v/(2L)$.

Just as we can make a string vibrate at multiples of the fundamental frequency, the pipe can also vibrate with large amplitude if excited by air pressure pulses at whole-number multiples of the fundamental frequency.

Standing wave vibration frequencies in open-open pipes The resonant frequencies f_n of air in an open-open pipe of length L in which sound travels at speed v are

$$f_n = n\left(\frac{v}{2L}\right) \text{ for } n = 1, 2, 3, \ldots \tag{11.13}$$

where v is the speed of sound in the medium that fills the pipe.

Standing waves in one-end-closed pipes—an open-closed pipe

Next, consider a pipe that is closed at one end and open at the other end, an **open-closed** pipe, such as a clarinet or the human throat (the closed end being the reed and vocal cords, respectively). Blowing into the reed initiates a high-pressure pulse near the closed end of the pipe. After reflection off the open end, a low-pressure pulse returns to the closed end of the pipe and reflects. However, reflection off the closed end causes it to remain a low-pressure pulse. The pulse has to make another complete round trip in the pipe before a high-pressure pulse returns to the reed. Thus, the pulse has to make two round trips, or travel a distance $4L$, before a new high-pressure pulse from the reed produces a fundamental frequency vibration. Thus, the fundamental frequency of an open-closed pipe is $f_1 = v/(4L)$ instead of $f_1 = v/(2L)$ for an open-open pipe. The fundamental frequency of an open-closed pipe clarinet is half the fundamental frequency of an open-open pipe flute of about the same length. Another difference is that the standing wave frequencies of open-closed pipes are not integer multiples of the fundamental but instead are odd whole-number multiples, as the even whole numbers would cause waves in the open-closed pipe that interfere destructively.

We can test our understanding of standing waves in pipes. If sound in pipe-like instruments is due to standing waves inside of them, and we change the medium (which changes the wave speed) inside a pipe, then we should observe the change of the fundamental frequency produced by the pipe even though the length of the pipe has not changed.

CONCEPTUAL EXERCISE 11.8 **Funny talk**

What should happen to a person's voice after inhaling helium and singing a note?

Sketch and translate The speed v of sound in helium gas (930 m/s) is much greater than in air (340 m/s), and the fundamental frequency f_1 is proportional to the speed of sound in the medium.

Simplify and diagram Model the vocal chamber as an open-closed pipe with the vocal cords at the closed end and the mouth at the open end. The length of the chamber does not change during the experiment. Since the speed of sound in helium is almost three times greater than in air, the fundamental frequency of the sound should increase by a factor of 3 and we should hear a higher pitch. Inhaling helium before singing or talking creates a very high pitched sound—as predicted. However, without measuring the frequency we cannot say how much greater the frequency is.

Try it yourself In our conceptual exercise with helium, we used gas with a greater speed of sound. What would happen if we could inhale a gas in which the speed of sound is lower than it is in air, such as CO_2?

Answer The pitch of one's voice would be lower. However, this gas is dangerous to inhale; nobody should perform this experiment. Thus this exercise is purely theoretical.

We can now formulate the conditions for standing waves in pipes with more confidence.

Standing wave vibration frequencies in open-closed pipes The resonant frequencies f_n of air in an open-closed pipe of length L in which sound travels at speed v are

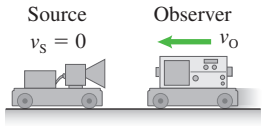
$$f_n = n\left(\frac{v}{4L}\right) \text{ for } n = 1, 3, 5, \ldots \tag{11.14}$$

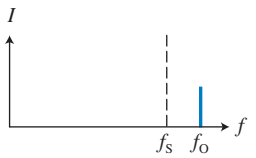
Exciting the sound and changing the pitch of a wind instrument

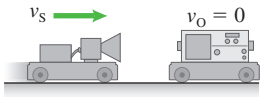
We can apply our understanding of standing waves in pipes to explain how wind instruments produce sounds of a particular frequency. In clarinets and saxophones, the sources of vibrations are the reeds. In trumpets, trombones, and French horns, the sources of vibrations are the vibrating lips and mouthpiece. The vibrations produced by the reeds and mouthpieces are not pure tones but are instead pressure pulses at a variety of frequencies. The pipes attached to the reeds and mouthpieces reinforce only those input frequency vibrations that are at resonant frequencies of the instruments.

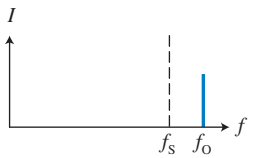
A resonant frequency for a particular instrument can be changed by opening one or more valves or keys. Opening the valve makes a hole that serves as the open end of the pipe. Thus, the air column length in the pipe is changed, as is its fundamental frequency. Because usually more than one resonant frequency is excited at a time, sound from the instrument consists of multiple resonant frequencies. The combination of resonant frequencies contributes in part to the quality of the sound from the instrument.

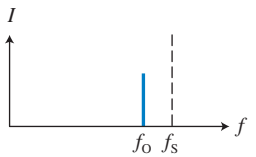
REVIEW QUESTION 11.9 When we studied traveling waves, we decided that the wavelength of a wave depends on the frequency of vibration and the speed of the wave in the medium. Is this statement true for standing waves in pipes?

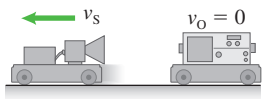


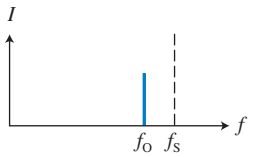


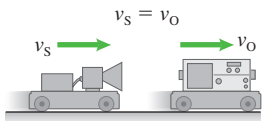


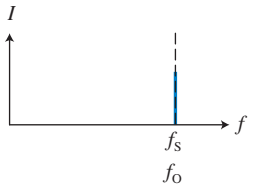












11.10 The Doppler effect

When you hear the sound from the horn of a passing car, its pitch is noticeably higher than its pitch at rest as it approaches and is noticeably lower as it moves away. This phenomenon is an example of the **Doppler effect**. The Doppler effect occurs when a source of sound and an observer move with respect to each other and/or with respect to the medium in which the sound travels.

Is there a pattern in these observed frequency shifts?

In Observational Experiment **Table 11.6**, we will investigate the Doppler effect, using a battery-powered whistle (the source) that generates a source frequency f_S and a detector (the observer) that records the observed sound and determines its frequency f_O using a special device called a spectrum analyzer. We will place each on a cart that can move toward or away from the other. In all experiments the air in which the sound propagates is at rest with respect to Earth. When both carts are at rest, the spectrum analyzer records frequency f_S.

OBSERVATIONAL EXPERIMENT TABLE 11.6 Effects of motion on observed frequency

Observational experiment		Analysis	
Place a battery-powered whistle (the source) on one cart and an observer with a spectrum analyzer on another cart. The carts can move toward or away from each other.			
(a) Source stationary with respect to the ground **Observer** moving toward source		The graph shows the frequency spectrum for the signal heard by the observer (f_O). The frequency of the source f_S is shown as a comparison. This is not the frequency that the observer records. $f_S < f_O$	
(b) Source moving toward observer **Observer** stationary with respect to the ground		The frequency spectrum: $f_S < f_O$	
(c) Source stationary with respect to the ground **Observer** moving away from source		The frequency spectrum: $f_S > f_O$	
(d) Source moving away from observer **Observer** stationary		The frequency spectrum: $f_S > f_O$	
(e) Source moving with respect to the ground **Observer** moving at the same speed in the same direction		The frequency spectrum: $f_S = f_O$	

Patterns

- (a) and (b) Source and/or observer are moving *toward* each other: the observed frequency is *greater than* the emitted source frequency.
- (c) and (d) Source and/or observer are moving *away from* each other: the observed frequency is *less than* the source frequency.
- (e) There is no relative motion: the observed and emitted frequencies are the same.

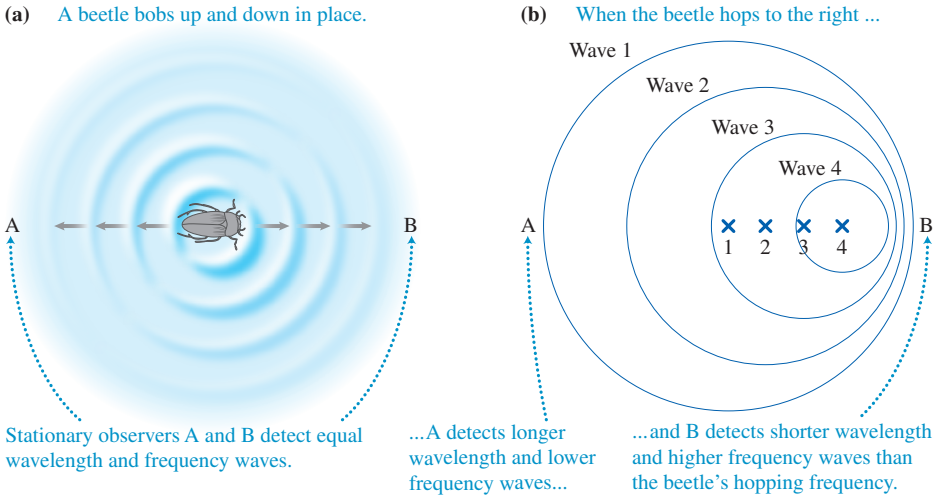
Let's develop a quantitative explanation for the patterns observed in Table 11.6.

Doppler effect for the source moving relative to the medium

We can use the waves created by a water beetle bobbing up and down at a constant frequency on the water to explain the Doppler effect. If the beetle bobs up and down in the same place, the pattern of wave crests appears as shown in **Figure 11.29a**. The crests move away from the source at a constant speed. The distance between adjacent crests is one wavelength and is the same toward observer A as toward observer B. The frequency of waves reaching both observers is also the same.

Now suppose the bobbing beetle moves to the right at a speed slower than the wave speed. Each new wave produced by the beetle originates from a point farther to the right (Figure 11.29b). As a result, B receives four wave crests in a shorter time interval than the source took to produce them, $f_O > f_S$. A receives four wave crests in a longer time than the source took to produce them, $f_O < f_S$.

FIGURE 11.29 (a) A bobbing beetle creates wave crests. (b) The wave crests created as the beetle hops to the right.



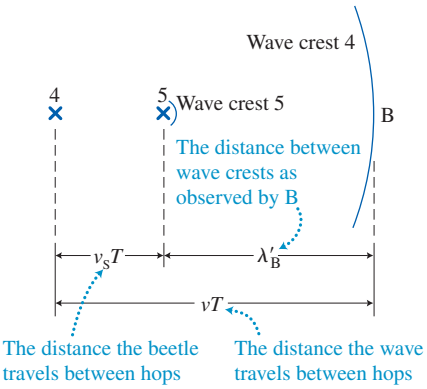


FIGURE 11.30 The wavelength is reduced in front of the hopping beetle.

To derive an equation for calculating the observed frequency, we first calculate the separation of crests in front of the beetle. Consider the separation of wave crest 4 and the wave initiated by the beetle's fifth step (wave crest 5, shown in **Figure 11.30**). If the beetle bobs up and down at frequency f_S, the time between the start of wave 4 and the start of wave 5 is $T = 1/f_S$. During this time interval, the beetle moves a distance $v_S T$ to the right, where v_S is the speed of the beetle (the wave source). Wave 4 has moved a distance vT during that same time interval, where v is the speed of the wave. The crests of waves 4 and 5 arriving at observer B are separated by a distance λ'_B (observed wavelength), given by

$$\lambda'_B = vT - v_S T$$

Similarly, the beetle is moving away from A (see Figure 11.29), and the wavelength of the wave reaching A is

$$\lambda'_A = vT + v_S T$$

The waves pass observer B at a frequency

$$f_{OB} = \frac{\text{wave speed}}{\text{wavelength}} = \frac{v}{\lambda'_B} = \frac{v}{T(v - v_S)} = \frac{1}{T}\frac{v}{(v - v_S)} = f_S \frac{v}{v - v_S}$$

where $f_S = 1/T$ is the source frequency. The waves are incident on observer A at frequency

$$f_{OA} = \frac{\text{wave speed}}{\text{wavelength}} = \frac{v}{\lambda'_A} = \frac{v}{T(v + v_S)} = \frac{1}{T}\frac{v}{(v + v_S)} = f_S \frac{v}{v + v_S}$$

Combining these two equations, we get

$$f_O = f_S \frac{v}{v \mp v_S} \tag{11.15}$$

We use the minus sign when the source is moving toward the observer and the plus sign when the source is moving away from the observer. This equation is consistent with the patterns discovered in Table 11.6.

Doppler effect for the observer moving relative to the medium

If the observer moves toward the source at speed v_O relative to the medium, the wave fronts appear to move past the observer at speed $v + v_O$ and the observer encounters the fronts more frequently than if she had remained stationary. If the observer moves away from the source, the wave fronts appear to move past the observer at speed $v - v_O$ and she encounters the fronts less frequently.

Mathematically,

$$f_O = \frac{v \pm v_O}{\lambda} = \frac{v \pm v_O}{v/f_S} = f_S \frac{v \pm v_O}{v} \tag{11.16}$$

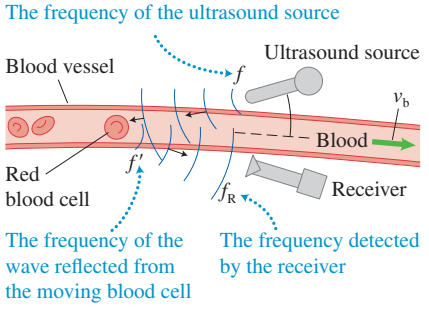
where λ is the wavelength that the observer who is not moving with respect to the source will record (λ in the medium). This equation can be used to calculate the frequency f_O detected by an observer moving at speed v_O toward (plus sign) or away from (minus sign) a stationary source emitting waves at frequency f_S.

General equation for the Doppler effect for sound

We arrive at a general equation for the Doppler effect by combining Eqs. (11.15) and (11.16).

Doppler effect for sound When a sound source and sound observer move, the observed sound frequency f_O differs from the source sound frequency f_S:

$$f_O = f_S\left(\frac{v \pm v_O}{v \mp v_S}\right) \tag{11.17}$$



where v is the speed of waves through the medium, v_O is the speed of the observer relative to the medium (use the plus sign if the observer moves toward the source and a minus sign if the observer moves away from the source), and v_S is the speed of the source relative to the medium (use the minus sign if the source moves toward the observer and a plus sign if the source moves away from the observer).

TIP Once you have chosen which signs to use in Eq. (11.17), check for consistency. When the source and observer are getting closer, $f_O > f_S$, and so on.

Measuring the speed of blood flow in the body

The Doppler effect is used to measure the speed of blood flow in the body. Ultrasound waves ($f > 20{,}000$ Hz) are directed into an artery (**Figure 11.31**). The waves are reflected by red blood cells back to a receiver. The frequency detected at the receiver f_R relative to that emitted by the source f_S indicates the blood cell's speed and the speed of the blood flow. This process has two parts. (1) The waves leave the source at frequency f_S and strike the cell at frequency f'. (2) The waves reflect from the cell at frequency f' and return to the receiver where they are detected at frequency f_R.

FIGURE 11.31 Using the Doppler effect to measure blood flow speed.

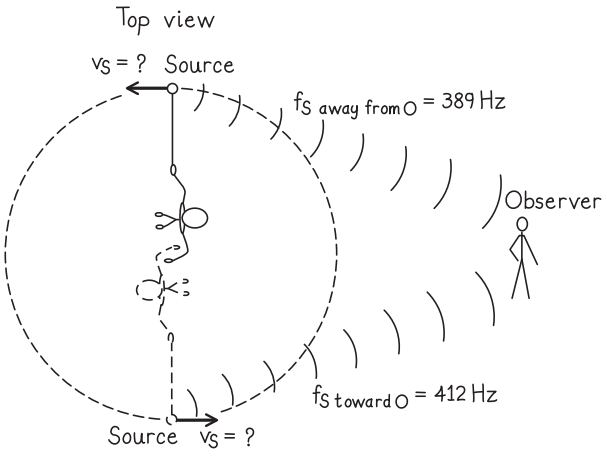
The frequency of the ultrasound f' striking a red blood cell is related to the frequency f_S emitted from the source by the equation

$$f' = f_S\left(\frac{v + 0}{v - v_b}\right) \tag{11.18}$$

where v is the speed of sound in blood and v_b is the speed of the blood. The red cells reflect this sound, acting like a source with frequency f'. Note that in this case the source is not moving with respect to the ground, but the medium is moving with respect to the source. Thus we have $-v_b$ in the equation. The frequency detected at the receiver f_R is related to f' by the equation

$$f_R = f'\left(\frac{v + v_b}{v - 0}\right)$$

Substituting for f' from Eq. (11.18), we find the frequency detected at the receiver f_R relative to the frequency emitted by the sound source f_S:



$$f_R = f_S\left(\frac{v + 0}{v - v_b}\right)\left(\frac{v + v_b}{v - 0}\right) = f_S\left(\frac{v + v_b}{v - v_b}\right) \tag{11.19}$$

This result allows us to measure the speed of blood using the Doppler effect.

EXAMPLE 11.9 Buzzer moves in a circle

A friend with a ball attached to a string stands on the floor and swings it in a horizontal circle. The ball has a 400-Hz buzzer in it. When the ball moves toward you on one side, you measure a frequency of 412 Hz. When the ball moves away on the other side of the circle, you measure a frequency of 389 Hz. Determine the speed of the ball.

Sketch and translate Draw a sketch of the situation. You detect a higher frequency when the ball moves toward you and lower frequency when it moves away, consistent with our understanding of the Doppler effect.

Simplify and diagram The speed of sound in air is constant and equals 340 m/s. The air is stationary with respect to the ground.

Represent mathematically We use Eq. (11.17) to find an expression for the ratio of the frequency when the source (the buzzer) is moving toward you (the observer) and when it is moving away. This ratio can then be rearranged to get an expression for the speed of the source (the buzzer):

$$\frac{f_{S\text{ moving toward O}}}{f_{S\text{ moving away from O}}} = \frac{f_S\dfrac{v + 0}{v - v_S}}{f_S\dfrac{v + 0}{v + v_S}} = \frac{v + v_S}{v - v_S}$$

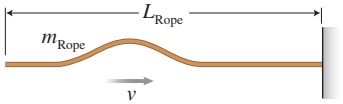
where v is the speed of sound in air and v_S is the speed of the source.

Solve and evaluate Solving for v_S, we get

$$v_S = \left(\frac{f_{S\text{ moving toward O}} - f_{S\text{ moving away from O}}}{f_{S\text{ moving toward O}} + f_{S\text{ moving away from O}}}\right)v$$

$$= \left(\frac{412\text{ Hz} - 389\text{ Hz}}{412\text{ Hz} + 389\text{ Hz}}\right)(340\text{ m/s}) = 9.8\text{ m/s}$$

The ball was moving at 9.8 m/s—the correct unit and a reasonable magnitude.

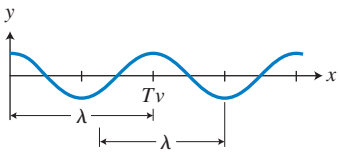


Try it yourself What frequency do you hear when the ball is moving perpendicular to your line of sight directly in front of you?

Answer and you should hear the buzzer's frequency of 400 Hz. At that instant, the ball is not moving toward or away from you—it moves in the perpendicular direction—there is no Doppler shift 400 Hz.

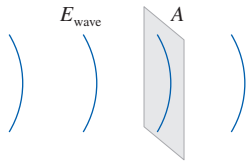
REVIEW QUESTION 11.10 An ambulance siren blares continuously as the ambulance approaches you and then moves away. How does the sound from the siren change and why?

Summary



Wave speed v depends on the properties of the medium (such as a force $F_{\text{M on M}}$ that one part of the medium exerts on another part and a mass/length quantity $\mu = m/L$). The *wavelength* λ is equal to the shortest distance between two points that vibrate in phase and depends on the frequency f and the wave speed v. (Sections 11.2 and 11.3)

$$\lambda = Tv = \frac{v}{f} \qquad \text{Eq. (11.3)}$$

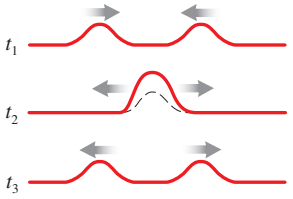


$$v = \sqrt{\frac{F_{\text{M on M}}}{\mu}} \qquad \text{Eq. (11.5)}$$

Traveling sinusoidal wave The traveling wave expression allows us to determine the displacement from equilibrium y of a point in the medium at location x at time t when a wave of wavelength λ travels at speed v. In a traveling wave all points vibrate with the same amplitude but have different phases. (Section 11.2)

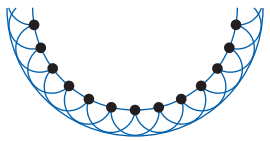
$$y = A\cos\left[2\pi\left(\frac{t}{T} - \frac{x}{\lambda}\right)\right] \qquad \text{Eq. (11.4)}$$

Intensity I of a wave is the energy per unit area per time interval that crosses an area perpendicular to the direction of travel of the wave.
Intensity level β is a logarithmic measure of the intensity I relative to reference intensity I_0. (Sections 11.4 and 11.7)



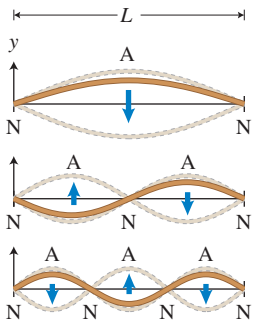
$$I = \frac{\Delta E}{\Delta t \cdot A} = \frac{P}{A} \qquad \text{Eq. (11.6)}$$

$$\beta = 10\log_{10}\left(\frac{I}{I_0}\right) \qquad \text{Eq. (11.8)}$$



where for sound $I_0 = 10^{-12}\ \text{J/m}^2 \cdot \text{s}$

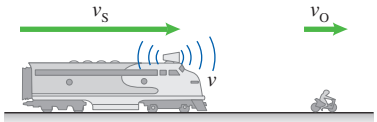
Superposition principle When two or more waves pass through the same medium at the same time, the net displacement of any point in the medium is the sum of the displacements that would be caused by each wave if alone in the medium. (Section 11.6)



$$y_{\text{net}} = y_1 + y_2 + y_3 + \cdots \qquad \text{Eq. (11.7)}$$

Huygens' principle Every vibrating point of a medium produces a wavelet surrounded by a circular wave front. The new wave front is the superposition of all wavelets due to the vibrations of all points on the previous wave front. (Section 11.6)

Standing waves are the result of the superposition of reflected waves of frequencies f_n traveling at speed v in both directions in a medium of length L. The vibrating points in a standing wave have different amplitudes, but all vibrate in phase. (Sections 11.8 and 11.9)



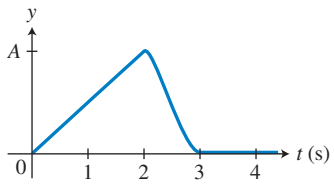
Strings: $f_n = n\left(\frac{v}{2L}\right)$ for $n = 1, 2, 3, \ldots$ Eq. (11.11)

Open-open pipes: $f_n = n\left(\frac{v}{2L}\right)$ for $n = 1, 2, 3, \ldots$ Eq. (11.13)

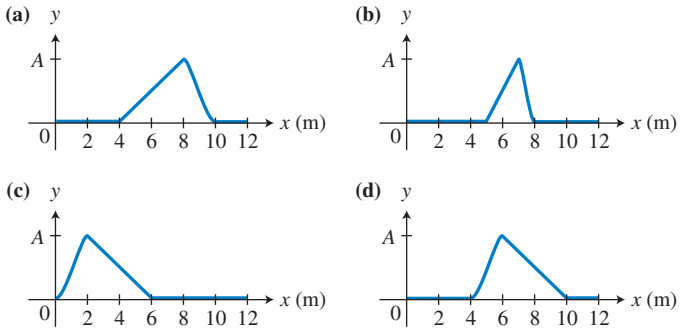
Open-closed pipes: $f_n = n\left(\frac{v}{4L}\right)$ for $n = 1, 3, 5, \ldots$ Eq. (11.14)

Doppler effect for sound When a sound source and sound observer move relative to each other, the frequency f_O of the observed sound differs from the frequency f_S of the source. v_O and v_S are the observer and source speeds (magnitudes of the velocities) and v is the speed of the wave through the medium. (Section 11.10)

$$f_O = f_S\left(\frac{v \pm v_O}{v \mp v_S}\right) \qquad \text{Eq. (11.17)}$$



Use + in front of v_O if observer moves toward source and − if away; use − in front of v_S if source moves toward observer and + if away. All speeds in this equation are relative to the medium.

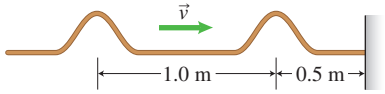


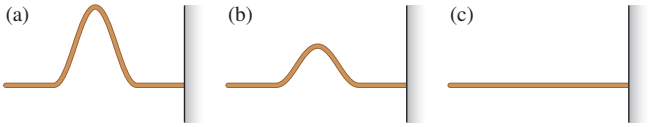
Questions

Multiple Choice Questions

1. What does it mean if the speed of a wave is 300 m/s?
   (a) Each particle moves at a speed of 300 m/s.
   (b) The wave disturbance travels 300 m during each second.
   (c) The wave disturbance travels 300 m for each wavelength.
   (d) The wave disturbance travels 300 m during each period.
2. What does it mean if the wavelength of a wave is 4.0 m?
   (a) The wave continues to travel for 4.0 m before stopping.
   (b) The period of the wave is 4.0 m.
   (c) The distance between the nearest particles that have identical displacements is 4.0 m.
3. If you wish to represent one period of a wave on a string, which two variables should you have on the axes?
   (a) v and T (b) y and x
   (c) y and t (d) T and λ
4. If you wish to graph the disturbance pattern of a wave on a long string at one clock reading, which two variables should you have on the axes?
   (a) y and λ (b) y and x
   (c) y and t (d) T and λ
5. Which mathematical expression represents a cause-effect relationship for a traveling wave?
   (a) $f = v/\lambda$ (b) $v = \lambda \cdot f$ (c) $\lambda = v/f$
6. Two small spheres vibrate up and down on the surface of a large tank of water. We observe places in the water where the surface does not vibrate. What are these statements?
   (a) A hypothesis
   (b) A description of a physical phenomenon
   (c) A physics law (d) A physical quantity
7. What is Huygens' principle?
   (a) A law describing the behavior of waves
   (b) A hypothesized mechanism of wave propagation
   (c) A physical phenomenon involving waves
   (d) A physical quantity describing waves
8. **Figure Q11.8** shows the displacement-versus-time graph of the left end of a 12-m-long rope. The wave speed on the rope is 2 m/s. Which graph below correctly shows a snapshot of the rope at a clock reading of $t = 5$ s?

FIGURE Q11.8





9. A small battery-operated buzzer emits sound at a constant frequency of $f_b = 3000$ Hz. If you drop the buzzer from the top of a tall building, what will you observe?
   (a) Sound at constant frequency $f_o = f_b$
   (b) Sound at constant frequency $f_o > f_b$
   (c) Sound at constant frequency $f_o < f_b$
   (d) Sound at increasing frequency $f_o > f_b$
   (e) Sound at decreasing frequency $f_o < f_b$
   (f) Sound at beat frequency $|f_o - f_b|$

Conceptual Questions

10. **Figure Q11.10** shows a snapshot of two pulses that are propagating with speed $v = 1.0$ m/s along a rope fixed to a wall at the right end. Which of the following shows the correct snapshot of the rope 1.0 s later?

FIGURE Q11.10

   (d) None of the above.

11. **Figure Q11.11** shows a snapshot of two pulses that are propagating with speed $v = 1.0$ m/s along a rope. The right end of the rope is fixed to a very light ring that can move along the vertical pole with no friction. Which of the following shows the correct snapshot of the rope 1.0 s later?

FIGURE Q11.11

   (d) None of the above.

12. Can a wave have a period of 2.0 s, a speed of 20 m/s, and a wavelength of 10 m?
13. What physics ideas were necessary to construct Eq. (11.4)? What math ideas did you need?
14. How do you know that the wavelength of a wave can be calculated by multiplying the speed of the wave in a medium by the period of the vibrating source?
15. What conditions are necessary to create a sinusoidal wave in a certain medium? What is needed to create a wave of a different frequency? Different speed? Different wavelength?
16. Invent and describe an experiment to estimate the speed of sound in air. You can use only everyday items.
17. How can you use the time delay between a lightning flash and the sound of thunder to estimate the distance to the place where the flash occurred? Justify any assumptions you make in an example calculation.
18. Describe two useful types of information a geologist can obtain by detecting sound reflected from different materials under Earth's surface.
19. Two speakers hang from racks placed in an open field. When sound of the same frequency comes from both speakers, no sound is heard in some locations. The sound is loud in other places at about the same distance from the speakers. Explain.
20. Two identical sound waves are sent down a long hall. Does the resultant wave necessarily have amplitude twice that of the constituent waves? Explain. Under what conditions would we hear no sound?
21. Sound waves of all frequencies in the audio frequency range (20–20,000 Hz) travel at the same speed in air. Explain how some common experiences support this statement.
22. How can you show that an object producing sound can be used to detect sound?
23. Describe the common features and differences between traveling waves and standing waves.
24. Why do different guitar strings sound different when you pluck them, even though they are the same length?

Problems

Below, BIO indicates a problem with a biological or medical focus. Problems labeled EST ask you to estimate the answer to a quantitative problem rather than derive a specific answer. Asterisks indicate the level of difficulty of the problem. Problems with no * are considered to be the least difficult. A single * marks moderately difficult problems. Two ** indicate more difficult problems.

11.1 and 11.2 Observations: pulses and wave motion and Mathematical descriptions of a wave

Assume that the speed of sound in air is 340 m/s for all of these problems unless stated otherwise.

1. Imagine that you and your friend pull tightly on the ends of a rope lying on a smooth floor. You shake your end of the rope, causing a transverse pulse. (a) Draw a displacement-versus-time graph representing the motion of your end of the rope. (b) Draw two displacement-versus-position graphs representing all of the points on the rope at two different clock readings.
2. Explain the meaning of each symbol in the equation

$$y = A\cos\left[\frac{2\pi}{T}\left(t - \frac{x}{v}\right)\right]$$

and summarize how we devised this equation.

3. * **Tell all** You have a sinusoidal wave that is described by the function

$$y = (0.2\text{ m})\sin\left[\frac{\pi}{2}\left(t + \frac{x}{20\text{ m/s}}\right)\right]$$

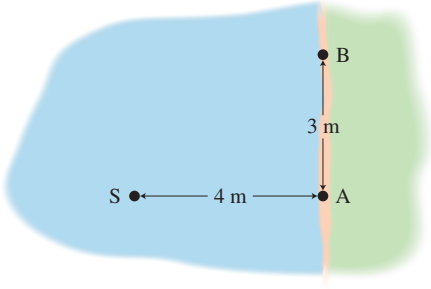
(a) Say everything you can about this wave. Pay attention to the positive sign in the equation. (b) Draw a y-versus-t graph and a y-versus-x graph for the wave.

4. * A transverse wave of amplitude 3.0 cm, frequency 2.0 Hz, and speed 3.0 m/s travels on an infinitely long Slinky. How far apart are the two nearest points on the Slinky that at one particular time both have the maximum displacements from their equilibrium positions? Explain your reasoning.
5. A boat is moving up and down in the ocean with a period of 1.7 s caused by a wave traveling at a speed of 4.0 m/s. What other physical quantities relevant to this wave can you determine using this information? Determine them.
6. * A large goose lands in a lake and bobs up and down for a short time. A fisherman notices that the first wave created by the goose reaches the shore in 8.0 s. The distance between two wave crests is 80 cm, and in 2.0 s he sees four waves hit the shore. How can the fisherman use these observations to determine how far from the shore the goose landed?
7. * **Equation Jeopardy** The equation below describes the variation of pressure at different positions and times (relative to atmospheric pressure) caused by a sound wave:

$$\Delta P = (2.0\text{ N/m}^2)\cos\left[2\pi\left(\frac{t}{0.010\text{ s}} - \frac{x}{3.4\text{ m}}\right)\right]$$

Say everything you can about this wave.

8. BIO **Hearing** People can hear sounds ranging in frequency from about 20 Hz to 20,000 Hz. Determine the wavelengths of the sounds at these two extremes. What assumptions are you making? If these assumptions are not correct, how will your answer change?
9. BIO **Dolphin sonar** A dolphin has a sonar system that emits sounds with a frequency of 2.0×10^5 Hz. Determine everything you can about this sound wave. Remember that the sounds emitted by the dolphin travel in water.
10. **Antarctic ice** Radio waves travel at a speed of 1.7×10^8 m/s through ice. A radio wave pulse sent into the Antarctic ice reflects off the rock at the bottom and returns to the surface in 32.9×10^{-6} s. How deep is the ice? What assumptions did you make to solve the problem?
11. **Lightning and thunder** You see a flash of lightning, and 2.4 s later you hear thunder coming from the same location. (a) Why is there this long delay? (b) How far away did the lightning flash occur? Justify any assumptions you make in your calculations.
12. * See Question 11.8. Draw a v_y-versus-x graph for the points on the rope at time $t = 5$ s if you know that $A = 0.10$ m.
13. Three waves are described by the following equations: $y_1 = 0.1\text{ m} \times \sin[(2\text{ s}^{-1})t + (3\text{ m}^{-1})x]$, $y_2 = -0.2\text{ m} \times \sin[(3\text{ s}^{-1})t - (2\text{ m}^{-1})x]$, $y_3 = 0.3\text{ m} \times \sin[(4\text{ s}^{-1})t - (4\text{ m}^{-1})x]$. (a) Rank the speeds of the waves from largest to smallest; (b) rank the wavelengths of the waves from largest to smallest; (c) rank the displacement magnitudes of the waves at $t = 0.5$ s, $x = 0.5$ m from largest to smallest.



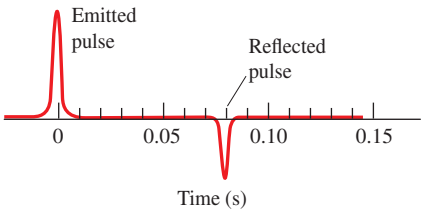
11.3 Dynamics of wave motion: speed and the medium

14. * **Ratio reasoning** Two ropes have equal length and are stretched the same way. The speed of a pulse on rope 1 is 1.4 times the speed on rope 2. Determine the ratio of the masses of the two ropes (m_1/m_2).
15. **Telephone line** A telephone lineman is told to stretch the wire between two poles so the poles exert an 800-N force on the wire. As the lineman does not have a scale to measure forces, he decides to measure the speed of a pulse created in the wire when he hits it with a wrench. The pulse travels 60 m from one pole to the other and back again in 2.6 s. The 60-m wire has a mass of 15 kg. Should the wire be tightened or loosened? Explain. What assumptions did you make?
16. * A pulse travels at speed v on a stretched rope. By what factor must you increase the force you exert on the rope to cause the speed to increase by a factor of 1.30? Indicate any assumptions that you made.
17. A 0.62-kg Slinky has 185 coils. When you and your friend stretch the Slinky by exerting a 2.0-N force on its ends, the separation between the adjacent coils is 7 cm. Determine the speed of the transverse wave on the Slinky.
18. * **Design** Describe two experiments to determine the speed of propagation of a transverse wave on a rope. You have the following tools to use: a stopwatch, a meter stick, a mass-measuring scale, and a force-measuring device. Use whatever other items you need for your experiments.
19. ** A 3-m rope is made of three 1-m-long sections. The first and last sections are made from rope with $\mu_1 = 100$ g/m, and the middle section is made from rope with $\mu_2 = 200$ g/m. When a pulse is produced at one end of the rope, it reaches the other end of the rope after 0.3 s. (a) Determine the speed of the transverse waves in both types of rope. (b) Determine the force exerted on the ends of the rope.

11.4 Energy, power, and intensity of waves

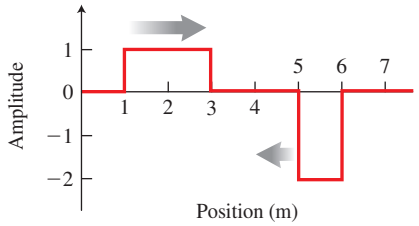
20. Show using a sketch and mathematics that the intensity of a two-dimensional wave is inversely proportional to the distance from a source. Give three examples that will explain the meaning of "inversely proportional to the distance" in this case. Assume there is no conversion of mechanical energy into thermal energy.
21. Show using a sketch and mathematics that the intensity of a three-dimensional wave is inversely proportional to the distance squared from the source. Give three examples that will explain what it means to be inversely proportional to the distance squared in this case. Assume there is no conversion of mechanical energy into thermal energy.
22. * You are standing at position A and your friend at position B on a lake shore (see Figure P11.22). Someone throws a ball so that it lands on the lake surface at point S. The ball produces a circular pulse that propagates along the water surface with a speed of 0.3 m/s. (a) Determine the time that elapses from the moment the pulse reaches you to the moment it reaches your friend. (b) Determine the ratio of the pulse amplitudes observed by you and your friend, assuming there is no damping.

FIGURE P11.22



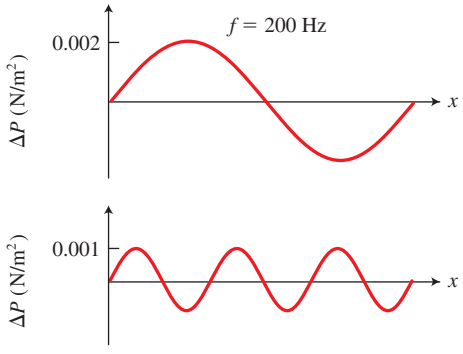
23. * A cicada is at the top of a 15.0-m-high tree, producing sound that is propagating in all directions. How far away from the tree should you stand so that the intensity of the sound that you hear is 10 times less than when you were standing at the bottom of the tree? Assume your height is 1.7 m.

11.5 and 11.6 Reflection and impedance and Superposition principle and skills for analyzing wave processes



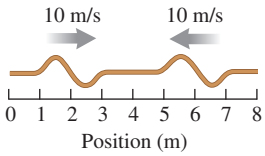
24. Explain why the transverse pulse traveling on a rope held by two people reflects in the opposite orientation each time it reaches a person.
25. **Design** Use your knowledge of waves to explain why echoes occur. Use your explanation to devise a system to measure distances to objects that cannot be reached directly.
26. BIO **Bat echo** A bat receives a reflected sound wave from a fly. If the reflected wave returns to the bat 0.042 s after it is sent, how far is the fly from the bat? Would you expect the reflected wave pulse to be in or out of phase with the incident wave pulse? Explain.
27. **Sound wave in Earth** A sound wave created by an explosion at Earth's surface is reflected by a discontinuity of some type under Earth's surface (Figure P11.27). Determine the distance from the surface to the discontinuity. Does the discontinuity have a greater or lesser impedance to sound than the surface above it? Explain. Sound travels at about 3000 m/s through the top layer of Earth.

FIGURE P11.27



28. A 5.0-kg rope that is 20 m long is woven to an 8.0-kg rope that is 16 m long. The ropes are pulled taut and a pulse initiated in one is reflected at their interface. Draw a snapshot of the rope just after the pulse reaches the interface between the ropes.
29. The pulses shown in Figure P11.29 (shown at time zero) are moving toward each other at speeds of 10 m/s. Draw $y(x)$ graphs showing the resultant pulse at 0.10 s, 0.20 s, and 0.30 s.

FIGURE P11.29

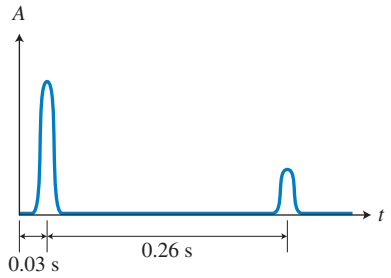


30. Repeat the previous problem for the case where the pulse on the right is upright rather than inverted.
31. * Find a resultant wave for the two waves shown in Figure P11.31 at the instant they are traveling through the same medium.

FIGURE P11.31

32. Two waves shown in Figure P11.32 at zero clock reading move toward each other at a speed of 10 m/s. Draw graphs of the resultant wave at times of 0.10 s, 0.20 s, and 0.30 s.

FIGURE P11.32

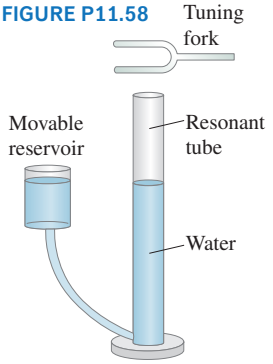


33. * Use Huygens' principle to find the shape of the wave fronts of a wave generated by the long edge of a flat piece of plastic floating horizontally and vibrating up and down in a swimming pool.
34. * Use Huygens' principle and a wave front representation of waves to show that if you place a screen with a small circular hole in the path of a wave with flat wave fronts, the wave fronts beyond the screen will be circular.
35. * Use Huygens' principle and a wave front representation of waves to find the locations in the swimming pool where no vibrations occur if two identical point-like objects synchronously vibrate in the pool. Assume the pool is infinitely large. In this case, neglect the decrease of amplitude with distance.
36. * You have two synchronously vibrating objects in an infinitely large pool. The distance between them is 6.0 m. Their frequency of vibration is 2.0 Hz and the wave speed is 4.0 m/s. The vibrations are sinusoidal. Find a location between them where the water does not vibrate and another location between them where the water vibrates with the largest amplitude. In this case, neglect the decrease of amplitude with distance.

11.7 Sound

37. **Design** Describe an experiment to convince a friend that sound is a wave.
38. The energy of a sound wave is proportional to its amplitude squared. Why is it difficult to hear poolside sounds when swimming underwater?
39. * **Warming with sound** The sound intensity at a gasoline station next to a freeway averages 10^{-3} W/m^2. The owner decides to collect this energy and convert it to thermal energy for heating his building. Assuming that this conversion is 100% efficient, what is the length of one side of a square sound collector that is needed to provide thermal energy at a rate of 500 W? Is this a practical idea for the owner? Explain.
40. * **Supersonic jet** The sound intensity 5 km from the place where a supersonic jet takes off is 0.60 W/m^2. Determine the area of a sound collector you would need to run a 40-W lightbulb from the energy collected. What might require you to create a larger collector?
41. * You are in an open field investigating how sound propagates. You place a rubber balloon 40.0 m away from you and pop the balloon with an air gun while while recording the sound produced by the gun and the popping balloon. Figure P11.41 shows your recording represented as a time dependence of the sound amplitude. (a) Explain what determines the amplitude of each pulse, what determines the time interval between $t = 0$ (when you triggered the gun) and the first pulse, and what determines the time interval between the pulses. (b) Can you estimate the speed of the bullet in this experiment based on the given data? Explain your answer. (c) Draw a new graph that you would expect to get if you repeated the experiment with the balloon 80.0 m away from you. Try to make your prediction as quantitative as possible. Indicate any assumptions that you made.

FIGURE P11.41



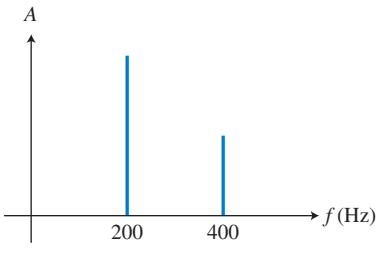
42. One loudspeaker is producing a tone of frequency 236.30 Hz and a second loudspeaker a tone of frequency 236.50 Hz. What is the shortest time interval that you have to listen to the sound from the two loudspeakers to hear three beats?

43. * Tovi is playing a flute and Dawn is playing a violin. At the beginning of the performance, they tuned their instruments by ear, so the difference between the fundamental frequencies of the A notes played on each instrument was less than 1 Hz. At the end of the performance, they measured the A note fundamental frequencies of their instruments using a device that measures sound frequency with uncertainty 0.05 Hz. Dawn's A was 442.6 Hz and Tovi's was 439.3 Hz. (a) Can you say for sure that the A note frequency of at least one musical instrument changed during the performance? (b) Can you say for sure that the A note frequency of both musical instruments changed during the performance? (c) What do Dawn and Tovi hear when they simultaneously play the A note at the end of the performance? Give a quantitative description.
44. **Music** In music a very soft sound called "pianississimo" (ppp) might have an intensity of about $10^{-8}\ \mathrm{W/m^2}$. A very loud sound called fortississimo (fff) might have an intensity of about $10^{-2}\ \mathrm{W/m^2}$. Convert these intensities to intensity levels (units of dB).
45. Two sounds differ by 1 dB. What is the difference in their intensities?
46. Calculate the change in intensity level when a sound intensity is increased by a factor of 8, by a factor of 80, and by a factor of 800.

11.8 and 11.9 Standing waves on strings and Standing waves in air columns

47. **Banjo string** A banjo D string is 0.69 m long and has a fundamental frequency of 294 Hz. (a) Determine the speed of a wave or pulse on the string. (b) Identify three other frequencies at which the string can vibrate.
48. **Banjo fret** How far from the end of the banjo string discussed in the previous problem must a fret be so that the string's fundamental frequency is 330 Hz when you hold it down at the fret?
49. * **Violin string** A 0.33-m-long violin string has a mass of 0.89 g. The peg exerts a 45 N force on it. What can you determine about the sound produced by that string?
50. A person secures a 5.0-m-long rope of mass 0.40 kg at one end and pulls on the rope, exerting a 120-N force. The rope vibrates in three segments with nodes separating each segment. List the physical quantities you can determine using this information and determine three of them.
51. * Laura and Elana are discussing how to solve the following problem: "A canary sits 10 m from the end of a 30-m-long clothesline, and a grackle sits 5 m from the other end. The rope is pulled by two poles that each exert a 200-N force on it. The mass per unit length is 0.10 kg/m. At what frequency must you vibrate the line in order to dislodge the grackle while allowing the canary to sit undisturbed?"
    Laura: "First we have to determine the wave speed on the rope. Then we have to find the frequency that will produce a standing wave with a node located at 10 m from the end."
    Elana: "I think there is no way that the canary would be undisturbed. You cannot make a standing wave without first sending a traveling wave along the rope."
    Comment on the students' suggestions. Explain how each student reached her conclusion and decide which parts of their statements are correct or incorrect.
52. * **Ratio reasoning** Two wires on a piano are the same length and are pulled by pegs that exert the same force on the wires. Wire 1 vibrates at a fundamental frequency 1.5 times that of wire 2. Determine the ratio of their masses (m_1/m_2).
53. * **Ratio reasoning** By what percent does the frequency of a piano string change if the force that the peg exerts on it increases by 10%?
54. (a) Determine the first three standing wave frequencies of a 40-cm-long open-open pipe. (b) Do the same for a 40-cm-long open-closed pipe.
55. * **Brooklyn-Battery Tunnel** The 2779-m Brooklyn-Battery Tunnel, connecting Brooklyn and Manhattan, is one of the world's longest underwater vehicular tunnels. (a) Determine its fundamental frequency of vibration. (b) What harmonic must be excited so that it resonates in the audio region at 20 Hz or greater?
56. * **Flute** A wooden flute, open at both ends, is 0.48 m long. (a) Determine its fundamental vibration frequency. (b) How far from one end should a finger hole be placed to produce a sound whose frequency is four-thirds that calculated in part (a)? Be sure to justify how you arrive at your answer.
57. **Organ pipe** The lowest three standing wave vibration frequencies of an organ pipe are 120 Hz, 360 Hz, and 600 Hz. (a) Is the pipe open or closed, and what is its length? (b) Determine the frequencies of the first two harmonic vibrations on a pipe of the same length but of the other type than that described in part (a).
58. The speed of sound can be measured using the apparatus shown in **Figure P11.58**. A 440-Hz tuning fork vibrating above a tube partially filled with water initiates sound waves in the tube. The standing sound waves are formed inside the tube when the water in the tube is lowered 0.20 m and 0.60 m from the top of the tube. Use this information to determine the speed of sound in air.

FIGURE P11.58



59. * Four strings of equal lengths are pulled with equal forces. All four strings are made to vibrate with standing wave frequencies. The table shows the vibration frequencies of the strings and the corresponding number of antinodes. Rank the masses of the strings from smallest to largest.

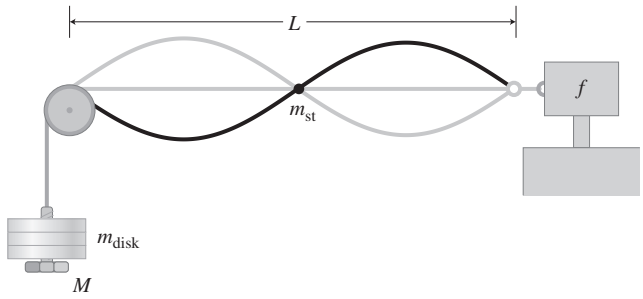
String #	Number of antinodes	f (Hz)
1	1	220
2	2	670
3	1	440
4	3	360

60. * A rope of length L is attached to a vibrating mechanism that vibrates with a constant frequency f. If a force F_1 is exerted on the ends of the rope, the rope is observed to vibrate in standing waves with three antinodes. Determine the force F_2 that has to be exerted on the end of the rope to make the rope vibrate in standing waves with two antinodes.
61. * A 3.0-m-long rope with a mass of 100 g is tied to a vibrating mechanism at one end and to a hook in a wall at the other end. The observed fundamental frequency of the rope is $f_1 = 7.0$ Hz. You modify the rope by attaching 2.0-g lead fishing weights every 10.0 cm along the entire rope. Determine the fundamental frequency of the modified rope. (Note: Since the wavelength is much larger than the separation between the nearest weights, we can assume that the mass is uniformly distributed along the modified rope.)
62. * A 1.2-m-long open-closed pipe is producing sound by vibrating with its third harmonic. (a) Determine the frequency of the sound. (b) How long should a pipe of the same type be to produce sound of the same frequency while at the fundamental frequency? (c) How would the answers to parts (a) and (b) change if the pipe was filled with helium, in which the speed of sound is about three times larger than in air? Explain.
63. * **Figure P11.63** shows the spectrum of sound that is produced by two pipes simultaneously vibrating with their fundamental frequencies. Each pipe can be either an open-open or an open-closed pipe. Determine all possible lengths of the pipes.

FIGURE P11.63

64. * See Problem 11.63. (a) Determine the length of the pipes if you know that the pipes have equal lengths. (b) Which frequency belongs to the open-closed pipe?
65. * See the spectrum in Figure P11.63. (a) Can this be a spectrum of the sound of an open-open pipe vibrating in its fundamental and next higher harmonic? Explain. (b) Can this be a spectrum of the sound of an open-closed pipe vibrating in its fundamental and first harmonic? Explain.

11.10 The Doppler effect



66. **Car horn** A car horn vibrates at a frequency of 250 Hz. Determine the frequency a stationary observer hears as the car (a) approaches at a speed of 20 m/s and (b) departs at 20 m/s. If the car is stationary, what frequency is heard (c) by an observer approaching the car at 20 m/s and (d) by an observer departing from the car at 20 m/s?
67. **Train whistle** A car drives at a speed of 25 m/s along a road parallel to a railroad track. A train traveling at 15 m/s sounds a horn that vibrates at 300 Hz. (a) If the train and car are moving toward each other, what frequency of sound is heard by a person in the car? (b) If the train and car are moving away from each other, what frequency of sound is heard in the car?
68. * BIO **Speed of blood** A source of ultrasound emits waves at a frequency of 2.00×10^6 Hz. The waves are reflected by red blood cells moving toward the source at a speed of 0.30 m/s. Determine the frequency of sound detected at a receiver next to the source. The speed of sound in the blood is 1500 m/s.
69. * **Circular motion sound source** A whistle with frequency 400 Hz moves at speed 20 m/s in a horizontal circle at the end of a rotating stick. Determine the highest and lowest frequencies heard by a person riding a bicycle at speed 10 m/s toward the whistle.
70. BIO **Bat echo** A bat emits short pulses of sound at a frequency of 1.60×10^5 Hz. As the bat swoops toward a flat wall at speed 30 m/s, this sound is reflected from the wall back to the bat. (a) What is the frequency of sound incident on the wall? (b) Consider the wall as a sound source at the frequency calculated in part (a). What frequency of sound does the bat hear coming from the wall?
71. ** **Detecting speed of baseball** A Doppler speed meter operating at exactly 1.02×10^5 Hz emits sound waves and detects the same waves after they are reflected from a baseball thrown by the pitcher. The receiver "mixes" the reflected wave with a small amount of the emitted wave and measures a beat frequency of 0.30×10^5 Hz. How fast is the ball moving?

General Problems

72. * **Violin strings** The speed of a wave on a violin A string is 288 m/s and on the G string is 128 m/s. Use this information to determine the ratio of mass per unit length of the strings. What assumptions did you make?
73. * Use Huygens' principle and a wave front representation of waves to show that a plane wave incident on a barrier traveling at an angle θ relative to a line perpendicular to the barrier (the so-called normal line) reflects, forming a wave front that travels at angle θ on the other side of the normal line.
74. * Use Huygens' principle and a wave front representation of waves to show that when a plane wave traveling in one medium hits a border with another different-speed medium that is not perpendicular to the direction of wave propagation, the wave changes its direction of propagation.
75. ** **Design** Describe an experiment that you can perform to measure the speed of sound in air using a graduated cylinder and a tuning fork that produces sound of a known frequency. Draw a picture. Carefully outline your experimental and mathematical procedure.
76. ** BIO EST **Reaction time** A basketball player's teammate shouts at her to catch a ball. Estimate the time required for the sound to travel a distance of 10 m, be detected by the ear, travel as a nerve impulse to the brain, be processed, then travel as a nerve signal for muscle action back to an arm, and finally cause a muscle contraction. Nerve impulses travel at a speed of about 120 m/s in humans. You will have to make reasonable assumptions about quantities not stated in the problem.
77. ** EST While camping, you record a thunderclap whose intensity is 10^{-2} W/m^2. The clap reaches you 3.0 s after a flash of lightning. Estimate the total acoustical power generated by the bolt of lightning. Clearly state all assumptions that you made.
78. ** BIO **Blood speed** A red blood cell travels at speed 0.40 m/s in a large artery. A sound of frequency 2.00×10^6 Hz enters the blood opposite the direction of flow. (a) Determine the frequency of sound reflected from the cell and detected by a receiver. (b) If the emitted and received sounds are combined in the receiver, what beat frequency is measured?
79. ** One end of a horizontal string of mass m_{st} and length $L = 0.8$ m passes over a pulley with a metal bolt of mass M hanging at the end. A motor attached to the other end of the string vibrates with a constant frequency $f = 18.0$ Hz. Some students add metal disks on the bolt and observe the vibration of the string. For certain masses of the added disks m_{disk}, they observe standing waves. When this happens, the students count the number of antinodes on the string n (**Figure P11.79** shows the setup for the $n = 2$ case). The students' data are presented in the table. (a) Derive an equation that relates m_{st}, L, f, n, m_{disk}, and M in cases when standing waves are observed. (b) Using the given data, estimate the mass of the string m_{st} and the mass of the bolt M. (Hint: Rearrange the equation that you derived in (a) to obtain the equation for m_{disk}. Then choose a new variable for which the equation represents linear dependence, plot the graph, and determine unknown quantities from the data that you obtained from the best-fit line.)

n	m_{disk} (kg)
4	0.100
3	0.250
2	0.700
1	3.100

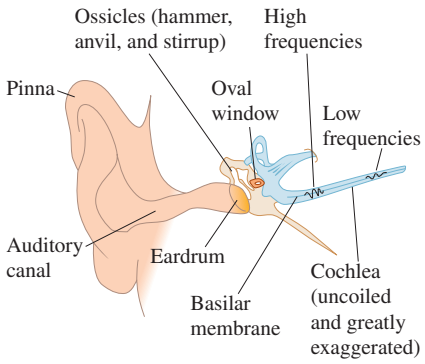
FIGURE P11.79

Reading Passage Problems

BIO **Bats and echolocation** If you shout "hello" near a vertical canyon wall, an echo "hello" returns after a short delay. If it returns in 2.0 s and sound travels through air at 340 m/s, then the total distance the signal traveled is 680 m. Therefore, the canyon wall must be half that distance from you (340 m). Bats use a similar process to hunt their prey. Bats travel and locate food at night by emitting ultrasound waves that bounce off prey and return to the bat. The time interval between signal emission and its return to the bat tells the bats which insects are closer than others. The amplitude of the reflected wave indicates the size of the prey— a large animal causes a large-amplitude reflected wave. The bat can tell the left-right location of the object by the relative time delays of the return sound between the left and right ears. Rows of horizontal folded sound sensors in the bat's ears allow them to determine the up-down location of the prey. Finally, the bat can determine if the prey is moving toward it, is moving away from it, or is stationary by the Doppler shift of the returning signal. The relationship between the source frequency of the bat and the frequency of the reflected sound is given by Eq. (11.19):

$$f_R = f_S\left(\frac{v + 0}{v - v_{P\text{ to }B}}\right)\left(\frac{v + v_{P\text{ to }B}}{v - 0}\right) = f_S\left(\frac{v + v_{P\text{ to }B}}{v - v_{P\text{ to }B}}\right)$$

80. You have a bat-like echolocation system on your car, which emits a 20,000-Hz frequency sound that returns to the car in 0.18 s after being reflected by another stationary car. Which answer below is closest to the distance from your car to the other car?
(a) 10 m (b) 20 m (c) 30 m
(d) 40 m (e) 60 m
81. If the car from Problem 11.80 is moving at 20 m/s toward the stationary car, which answer below is closest to the frequency of the reflected wave detected by the moving car from the stationary car?
(a) 18,000 Hz (b) 19,000 Hz (c) 20,000 Hz
(d) 21,000 Hz (e) 23,000 Hz
82. Which answer below is closest to the distance that the moving car in Problem 11.81 travels during the 0.18 s?
(a) 0.18 m (b) 0.36 m (c) 1.8 m
(d) 3.6 m (e) 5.4 m



83. Compare your answers to Problems 11.80 and 11.82. If you want a more accurate measure of the object's distance from you, you must consider the distance you travel during the time delay for the sound to get from you to the object and back to you. By approximately what percent does your change in position affect the distance calculated in Problem 11.80?
(a) 6% (b) 12% (c) 18%
(d) 24% (e) 30%

84. While your car from Problem 11.80 is stationary, you emit a 20,000-Hz signal and get a 22,000-Hz signal back from a reflecting object. What can you say about the object?
(a) It is moving away from you.
(b) It is stationary.
(c) It is moving toward you.

85. Your echolocation system has one transmitter in the middle of the front of the car and two detectors of reflected waves, one by each headlight (like the bat's ears). You detect a reflected signal in the left detector slightly before you detect the signal from the right detector. Where must the reflecting object be?
(a) To the left of center
(b) Straight in front of you
(c) To the right of center

BIO Human ear In the human ear (shown in **Figure 11.32**), the exterior ear flap, called the pinna, gathers and guides sound waves into the auditory canal. The sound waves create a pressure variation at the eardrum, a variation that is about two times as great as it would be without the pinna and auditory canal. This pressure variation causes the eardrum to vibrate. A large fraction of the vibrational energy is transmitted through the three small bones in the middle ear called the hammer, anvil, and stirrup. These three bones, collectively known as the ossicles, constitute a lever system that increases the pressure exerted on a small membrane of the inner ear known as the oval window. The pressure increase is possible for two reasons.

FIGURE 11.32

(1) The hammer feels a small pressure variation over the large area of its contact with the eardrum, whereas the stirrup exerts a large pressure variation over the small area of its contact with the oval window. This difference in areas increases the pressure by a factor of 15 to 30. (2) The three bones act as a lever that increases the force that the stirrup exerts on the oval window, although the displacement resulting from the force is less than if the bones were not present. Because of these effects, pressure fluctuation of the stirrup against the oval window can be 180 times greater than the pressure fluctuation of a sound wave in air before it reaches the ear.

The increased pressure fluctuation against the oval window causes a fluctuating pressure in the fluid inside the cochlea of the inner ear. The fluctuating pressure is sensed by nerve cells along the basilar membrane. Nerves nearest the oval window respond to high-frequency sounds, whereas nerves farther from the window respond to low-frequency sounds. Thus, our ability to distinguish the frequency of a sound depends on the variation in sensitivity of different cells to different frequencies along the basilar membrane. The basilar membrane is only about 3 cm long, yet a normal ear can distinguish sounds that differ in frequency by about 0.3%. This ability to distinguish sounds of slightly different frequency spans the human hearing range from about 20 Hz to 20,000 Hz.

86. The human ear can detect sound waves whose intensity is about $10^{-12}\ \mathrm{W/m^2}$. Where should you be with respect to a stereo speaker that produces sound of intensity $10^{-5}\ \mathrm{W/m^2}$ when 1 m from the speaker if you do not want to listen to the music?
(a) About 3 m away (b) About 30 m away
(c) About 3 km away
(d) It depends on the size of the speaker.

87. What amplifies the air pressure in the ear?
(a) Pinna (2 times) and ossicles (30 times)
(b) Pinna (2 times), auditory canal (3 times), and ossicles (30 times)
(c) Pinna and auditory canal (2 times), the area change from the eardrum to the oval window (30 times), and the lever action of the ossicles (3 times)

88. Where is the mechanism that allows the ear to distinguish between low-frequency and high-frequency sounds?
(a) The fluid inside the cochlea of the inner ear
(b) In the oval window
(c) In the basilar membrane (d) Both b and c

89. What frequency difference can the human ear distinguish near 1000 Hz?
(a) 100 Hz (b) 10 Hz (c) 3 Hz
(d) 1 Hz

90. The threshold for pressure variation of a barely audible sound is about $2 \times 10^{-5}\ \mathrm{N/m^2}$. Which answer below is closest to the pressure variation of a barely audible sound in the cochlea of the inner ear?
(a) $1 \times 10^{-7}\ \mathrm{N/m^2}$ (b) $1 \times 10^{-6}\ \mathrm{N/m^2}$
(c) $2 \times 10^{-5}\ \mathrm{N/m^2}$ (d) $4 \times 10^{-3}\ \mathrm{N/m^2}$
(e) $4 \times 10^{-2}\ \mathrm{N/m^2}$

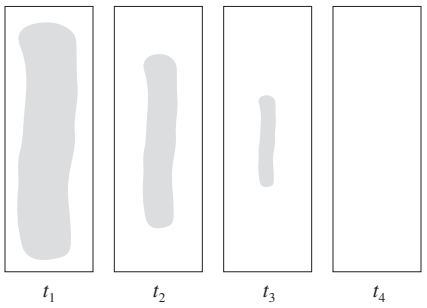
12 Gases

- **Why does a plastic bottle left in a car overnight look crushed on a chilly morning?**
- **How hard is air pushing on your body?**
- **How long can the Sun shine?**

When you inflate the tires of your bicycle in a warm basement in winter, they tend to look a bit flat when you take the bike outside. The same thing happens to a basketball—you need to pump it up before playing outside on a cold day. An empty plastic bottle left in a car looks crushed on a chilly morning. What do all those phenomena have in common, and how do we explain them?

BE SURE YOU KNOW HOW TO:

- Draw force diagrams (Section 3.1).
- Use Newton's second and third laws to analyze interactions of objects (Section 3.7 and 3.8).
- Use the impulse-momentum principle (Section 6.3).



IN CHAPTER 11, we learned that sound propagates due to the compression and decompression of air. But what exactly is being compressed? To answer this question and the ones above, we need to investigate what makes up a gas and how certain properties of gases can change.

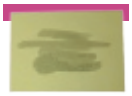
12.1 Structure of matter

When we look at objects that surround us, we do not see their internal structure—water in a cup looks homogeneous, and the cup itself looks like one piece of material. However, they must be made up of *something*. What are the building blocks of matter? To begin to answer this question, consider a simple observational experiment.

Imagine that you dip a cotton ball in rubbing alcohol and wipe it across a piece of paper (**Figure 12.1**). The wet alcohol strip disappears gradually, with the edges of the strip disappearing first. You observe the same behavior when you wipe water or acetone on the paper, except that the water strip disappears more slowly and the acetone strip disappears more quickly. This phenomenon is the same one we observe with wet clothes and puddles as they dry.

FIGURE 12.1 A disappearing moist strip on a piece of paper.

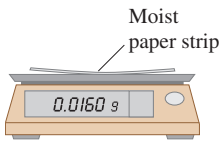
Since the alcohol disappeared gradually, it is reasonable to suggest that it is made of "pieces" too small to be seen. If the alcohol were composed of one piece, it would be gone all at once. However, the model of small pieces does not explain *how* the disappearance occurs. Let's try to construct some possible *mechanisms* that explain how the alcohol disappears (these mechanisms would also be applicable to the drying of water or acetone). Three of the many possible mechanisms are described below:



Mechanism 1. The little pieces of liquid move to the *inside* of the paper and are still there, even though the paper looks dry.

Mechanism 2. The air surrounding the paper somehow pulls the liquid pieces out of the paper.

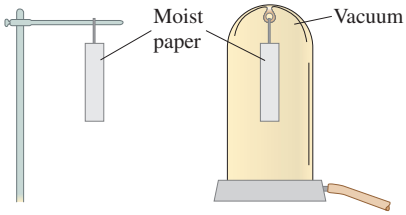
Mechanism 3. The pieces of liquid are moving—they bump into each other and slowly bump each other out of the paper one by one.



All of these mechanisms seem viable. Testing Experiment **Table 12.1** will help us decide if we can rule out any of them. To make predictions based on these three mechanisms, we will assume that the pieces comprising the alcohol have mass.

TESTING
EXPERIMENT TABLE 12.1

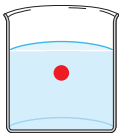
Testing various mechanisms for the drying of wet objects



VIDEO
TET 12.1

Testing experiment 1	Prediction	Outcome
Weigh a dry strip of paper on a sensitive scale. Record its mass. Then moisten the paper with alcohol and record the mass of the wet paper. What happens to the mass of the strip when it dries?  	**Mechanism 1.** If the alcohol pieces go "inside" the paper, then the mass of the paper after it dries should be greater than it was before it was made wet and exactly the same as it was just after it was made wet. **Mechanism 2.** If the air is somehow responsible for removing the alcohol pieces, then after the paper dries, it should have the same mass as it had before it was made wet. **Mechanism 3.** If the moving alcohol pieces bump each other out of the paper, then after the paper dries it should have the same mass as it had before it was made wet.	After the paper dries, its mass is the same as before it was made wet.

Conclusion 1



The alcohol pieces left the paper. Mechanism 1 is disproved by this experiment, but Mechanisms 2 and 3 are consistent with it. This leaves us with only two possible mechanisms.

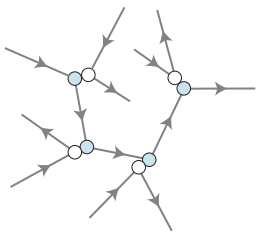
(CONTINUED)

Testing experiment 2	Prediction	Outcome
Moisten two strips of paper. Place one inside a sealed glass jar attached to a vacuum pump. Place the other strip outside the jar. Pump the air from the jar. 	**Mechanism 2.** If the air is somehow responsible for removing the alcohol pieces out of the strip, then the strip inside the vacuum jar with little air should dry more slowly than the strip outside the jar. **Mechanism 3.** If the moving alcohol pieces bump each other out of the paper, then the strip inside the vacuum jar should not dry more slowly than the strip outside the jar.	The paper inside the evacuated jar dries faster.

Conclusion 2

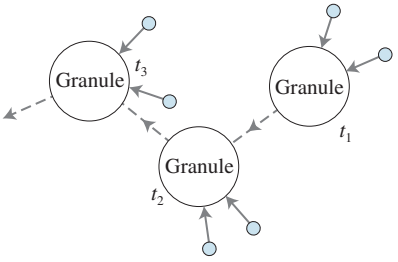
Mechanism 2 is disproved by this experiment. Mechanism 3 is not disproved by it.[1] Now we have only one mechanism that has not been disproved.

Testing experiment 3	Prediction	Outcome
Add a droplet of colored alcohol to a glass of clear alcohol. What happens to the colored droplet? 	**Mechanism 3.** If the small pieces of clear alcohol are moving and bumping each other, then they should bump the colored pieces and cause them to spread.	The color slowly spreads throughout the clear alcohol. 



Conclusion 3

Mechanism 3 is supported by this experiment.



[1]Note that while Mechanism 3 was not disproved in Experiment 2, the mechanism does not explain why the strip in the vacuum jar actually dried faster.

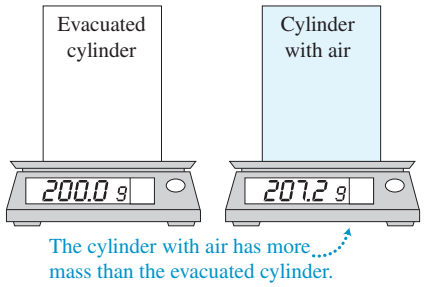
FIGURE 12.2 Random motion of water particles and pollen granules.

(a) The shaded water particle moves randomly due to collisions with other water particles.

(b) Water molecules collide with the pollen granule and cause it to move in random directions.

Based on these experiments, it is reasonable to assume that alcohol and other liquids are composed of smaller objects, called **particles**, which move randomly in all directions. These particles need empty space between them so that particles of other materials can move between them, as happened in Experiment 3 in Table 12.1. This model of the internal structure of alcohol can be used to explain many other phenomena that we encounter—the way some liquids mix or smells spread. In fact, experiments such as those described in Table 12.1 could have led the Greek philosopher Democritus (460–370 B.C.) to the *atomistic* model. *Atomos* in Greek means *indivisible*. According to Democritus, matter was composed of small, indivisible pieces with different shapes and properties. Democritus also suggested that the pieces were separated by tiny regions of completely empty space, which is a crucial idea as we understand now. Democritus proclaimed, "There is nothing in the world but atoms and empty space."

In 1827, Scottish botanist Robert Brown was observing pollen in a droplet of water through a microscope. To his surprise, the pollen granules were moving randomly, stopping, and then continuing in a different direction after each stop. To explain his observations, Brown used Mechanism 3—that water itself is composed of particles smaller than the granules and these particles move randomly between frequent collisions (**Figure 12.2a**). The water particles randomly hit the pollen granules from all directions and caused random changes in the position of a granule (Figure 12.2b). This experiment supported the model of water composed of invisible particles that were in continual random motion.



In 1905, Albert Einstein constructed a quantitative model to describe the phenomenon observed by Brown, called *Brownian motion.* He predicted the average distance that a granule of a certain size would move in a given time interval under specific conditions. Later, Jean Perrin conducted experiments whose outcomes matched Einstein's predictions. Physicists consider Perrin's experiments strong support for the *particle structure of matter.*

We now know that **atoms** are the smallest objects that still retain the chemical properties of a particular element (hydrogen, oxygen, carbon, iron, gold, etc.). Atoms of these various elements combine to build solids, liquids, and gases. A **molecule** is a certain combination of atoms that bond together in a particular arrangement. Molecules may consist of two atoms (such as oxygen, O_2, and nitrogen, N_2), three atoms (such as water—two hydrogen atoms and one oxygen atom, H_2O), or many atoms. Protein molecules can consist of thousands of atoms. Atoms are composed of fundamental particles—protons, neutrons, and electrons. We will discuss these fundamental particles later in the book (Chapters 28 and 29). For now, we will use the word *particle* to indicate an object approximately the size of a molecule or smaller. Our investigations and the history of physics bring us to a *particle model* of the internal structure of matter. In this model the matter is made of small particles that move randomly. The space between the particles is completely empty. We will learn later what conditions affect particle motion. We will also learn how these particles interact with each other.

The particle model explains how we can smell things even when we are not near them. Suppose we open a bottle of perfume while standing in the middle of a room. Several minutes later, people all over the room can smell the perfume. According to the particle model, the little particles of perfume leave the bottle and gradually disperse, eventually arriving at our nostrils. Since everyone in the room eventually smells the perfume, the perfume particles must move in all directions. However, it takes time to smell the perfume if you are far away from the bottle. Why is that? Perfume particles leaving the bottle move quickly but collide with air particles along the way and reach your nose only after many collisions.

If air is composed of tiny particles, and those particles have mass, then air must have mass. We can test this hypothesis with another simple experiment. Take two identical rigid metal cylinders—one that has had the air evacuated with a vacuum pump, and the other filled with air. Then weigh them. If the hypothesis that air has mass is correct, the evacuated cylinder should weigh less than the unevacuated cylinder. The cylinder filled with air is indeed heavier than the evacuated cylinder (**Figure 12.3**). However, the difference in masses is small, about 7 g for cylinders of about $6 \times 10^{-3}\,m^3$ (1.5 gallons). Air particle composition can also help us explain the propagation of sound. The propagating disturbances are the regions of air particles closer together or farther apart.

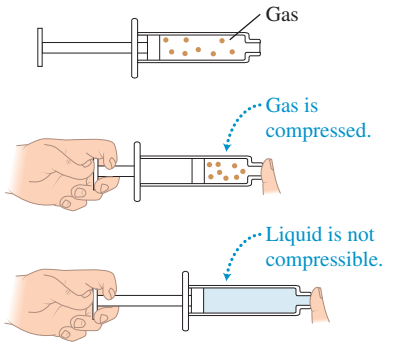


FIGURE 12.3 Air has mass.

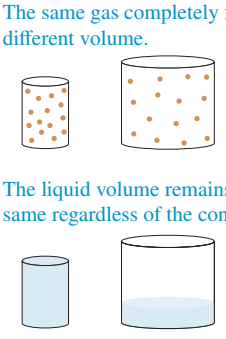
Gases, liquids, and solids

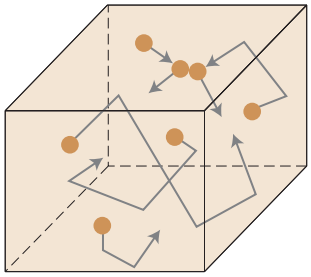


We know from experience that gases are easy to compress, while liquids and solids are almost incompressible (**Figure 12.4**). The particle model helps us explain this difference: we assume that matter in all states is composed of small particles, but the amount of empty space between the particles is different in solids, liquids, and gases. In solids and liquids, the particles are closely packed (almost no empty space between them), while in gases the particles are packed more loosely (lots of empty space).

FIGURE 12.4 A gas can be compressed, but a liquid cannot.

Gases tend to occupy whatever volume is available. If you take the air that fills a small cylinder and move it to a much larger cylinder, the air also fills the large cylinder (**Figure 12.5a**). In contrast, if we move the liquid filling a small container to a much larger container, the liquid volume remains the same independent of the container's shape (Figure 12.5b). Solids maintain not only their volume but also their shape. To distinguish them from solids, gases and liquids are sometimes called *fluids*. We will learn more about fluid behavior in Chapters 13 and 14.

FIGURE 12.5 Although gases and liquids are both fluids, they do not share all the same properties.



In order for particles to form a substance, the particles must somehow be attracted to each other. We will learn later (in Chapters 17 and 28) that although the nature of this attractive force between particles is different from their gravitational attraction for each other, there are some similarities between the two types of attraction. For instance,

in both cases the particles are attracted to each other at a distance, without any direct contact. The behavior of gases indicates that particles in gases must be so far from each other that such attractive forces are very small or even negligible. In liquids, the particles are closer together, and these new attractive forces between them are strong. In solids they are even stronger.

Ideal gas model

From the observed behavior of gases and our explanations based on the particle nature of matter, we can conclude that gases will be the easiest to study, as we can neglect the interactions of the particles at a distance. We start by constructing a simplified model of a gas as a system.

FIGURE 12.6 Ideal gas model.

In this model, we assume that the average distance between the particles (molecules or atoms) is much larger than the size of the particles. We assume that the gas particles are point-like objects that only interact with each other and with any surfaces in their containers during collisions (**Figure 12.6**), similar to the impulsive interactions of a billiard ball with a side of a pool table. In our model the particles do not attract each other at a distance the way they do in solids and liquids. We also assume that the motions of these particles obey Newton's laws. Thus, between collisions the particles move in straight lines at constant velocity and only change their velocities during collisions. Altogether, these simplifying assumptions make up the **ideal gas model**.

Ideal gas model A model of a system in which gas particles are considered point-like and only interact with each other and the walls of their container through collisions. This model also assumes that the particles and their interactions are accurately described using Newton's laws.

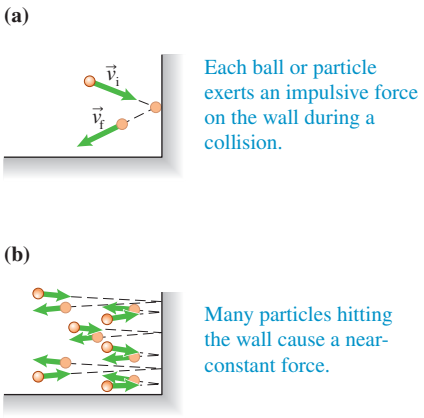
Ideal in this context does not mean perfect; it means *simplified*. This is a simplified model with certain assumptions. Whether or not this model can be used to represent a real gas remains to be seen. Only testing experiments can resolve that issue.

How useful is this new model of a gas? As with our previous models of objects (point-like objects, rigid bodies), we will use it to describe and explain known phenomena and then to predict new phenomena. However, so far our model is only qualitative. We need to devise physical quantities to represent the features and behavior of the model. This process will then allow us to construct a mathematical description of an ideal gas and predict its behavior.

REVIEW QUESTION 12.1 Use the particle model to explain how moist objects dry out.

12.2 Pressure, density, and the mass of particles

In this section we will identify several new physical quantities that are useful for describing the properties of the model of an ideal gas. These quantities are also applicable to the properties of real gases, liquids, and solids.

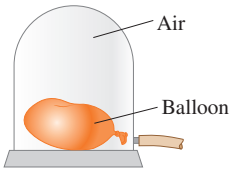


Gas pressure

Imagine you are holding an air-filled balloon. Try to crush it a little bit. You feel the balloon resisting the crushing, as if something inside it pushes back on your fingers. You might think it is the rubber resisting your squeeze, but what makes the rubber bulge out

in the same way in all directions? The balloon is filled with air. As we will learn later in this section, the particles of matter (atoms and molecules) are rather small. As air particles move randomly in space, they eventually collide with the solid surfaces of any objects in that space. In each of these collisions, the particle exerts an impulsive force on the object—like a tennis ball hitting a practice wall (see **Figure 12.7a**). However, when a huge number of particles bombard a solid surface at a constant rate, these collisions collectively exert an approximately constant force on the object (Figure 12.7b). This impulsive force must be what we feel when we are trying to squeeze the balloon. Notice that we have now constructed a *model of a process* that explains how the motion of the particles of gas inside the balloon accounts for the observational evidence—the apparent resistance of the balloon to squeezing. This ideal process that we imagined serves as a mechanism for what we observe.

We can test this process model with a simple experiment. When we blow up a balloon, filling it with air, we should not forget that there is also air outside the balloon. It is this outside air that will help us do the testing experiment described in Testing Experiment **Table 12.2**.



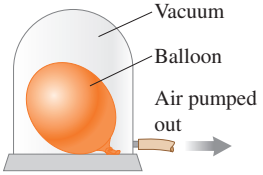


FIGURE 12.7 Impulsive forces during collisions cause an approximately constant force against a wall.

TESTING EXPERIMENT TABLE 12.2

Testing the model of moving gas particles pushing on the surface

VIDEO TET 12.2

Testing experiment	Prediction	Outcome
Place a partially inflated balloon inside a vacuum jar. Seal the jar.  What happens to the balloon's shape when you start pumping air out of the jar?	As we remove air particles from outside the balloon, the collisions of particles on the outside of the balloon are less frequent and exert less force on each part of the balloon's outer surface. The collision rate of the particles inside the balloon does not decrease. Therefore, the balloon should expand.	As air outside of the balloon is removed, the balloon expands. 

Conclusion

The model of air consisting of moving particles colliding with objects exposed to the air has not been disproved.

In normal situations, an extremely large number of gas particles collide each second with the surface that is in contact with the gas. For example, about 10^{23} particles of air collide each second with each square centimeter of your skin. Making a force diagram for the skin by including these individual particle collision forces is not practical. A different approach is needed.

As we have discussed, although each particle collision is impulsive, the forces are so small and so frequent that the force exerted by the gas on the walls of the container can be modeled as a single constant force. The force also depends on the area of that surface—the bigger the area, the more particles push on it during collisions. Thus, instead of using force to describe gas processes, we use the physical quantity of **pressure**, which we learned about in Chapter 11.

Pressure P Pressure is a physical quantity equal to the magnitude of the perpendicular component of the force, $F_\perp$, that a gas, liquid, or solid exerts on a surface divided by the contact area A over which that force is exerted (see **Figure 12.8**):

$$P = \frac{F_\perp}{A} \qquad (12.1)$$

FIGURE 12.8 The quantity pressure.

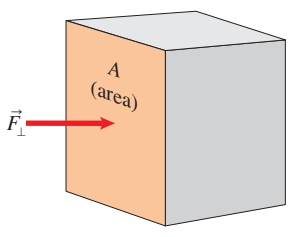

TABLE 12.3 Pressure units

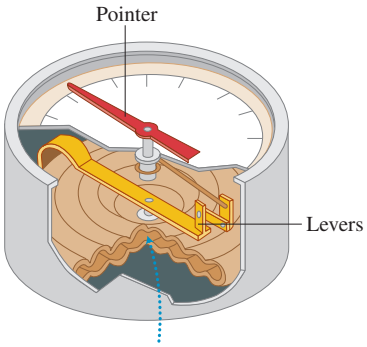
$1\ \text{atm} = 1.01 \times 10^5\ \text{N/m}^2 = 14.7\ \text{lb/in.}^2$
$= 760\ \text{mm Hg}$
$1\ \text{Pa} = 1\ \text{N/m}^2 = 1.45 \times 10^{-4}\ \text{psi}$



The SI unit of pressure is the pascal (Pa), where $1\ \text{Pa} = 1\ \text{N/m}^2$. In British units, pressure is measured in pounds per square inch (psi). Table 12.3 gives common pressure unit conversions.

Pressure is easy to visualize when you think about two solid surfaces that contact each other. Compare the magnitude of force you exert on soft snow when wearing street shoes versus the magnitude of force that you exert on the snow when wearing snowshoes. The magnitude of force that you exert on the snow is the same, but the corresponding pressure is not. The snowshoes decrease the pressure you exert on the snow, since the force is spread over a much larger area. Similarly, when you decrease the area over which the force is spread, the pressure increases. Scissors and knives increase pressure on a surface because they decrease the area over which they exert a force.

Does a gas exert pressure inside itself, or does it only press on the walls of its container? Let us think about the air in a room. The air particles hitting one wall in the room collectively exert an average force on the wall, and therefore a pressure. However, the air particles in the center of the room are not interacting with the wall at all, at least not for the moment. Yet the air there has a pressure as well. If a table were placed in the center of the room, the air particles would exert an average force, and therefore a pressure, on the top, bottom, and sides of the table. Thus, air has a pressure whether or not a solid object is present.

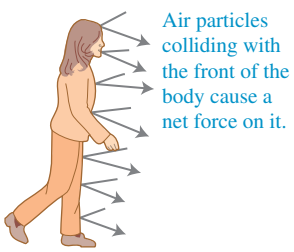
Measuring pressure

FIGURE 12.9 An aneroid barometer.

Many instruments are used to measure pressure. An aneroid barometer is used to measure gas pressure directly. The barometer contains a small aneroid cell (Figure 12.8). Inside, the cell has almost no air. A lever is attached to the cell's moveable wall. As the outside air pressure on this wall changes, the cell thickness changes, and the lever causes a pointer needle on the aneroid barometer to turn, indicating the outside air pressure. Measurements show that the pressure of the atmospheric air at sea level is on average $10^5\ \text{N/m}^2$, or $10^5\ \text{Pa}$. This atmospheric pressure defines yet another unit of pressure, called an atmosphere: $1.0\ \text{atm} = 1.0 \times 10^5\ \text{Pa} = 1.0 \times 10^5\ \text{N/m}^2$.

Another way to measure gas pressure is to compare the pressure of a gas in contact with a gauge to the atmospheric pressure, as we did in Chapter 11 when studying sound waves. For example, when you use a tire gauge to measure the air pressure in a car tire, you are comparing the air pressure inside the tire to that of the atmosphere outside the tire. The pressure in the tire is called **gauge pressure**. If the pressure in a container is 1.0 atm, its gauge pressure is zero, because there is no difference between the pressure inside the container and outside of it.

Gauge pressure P_{gauge} Gauge pressure is the difference between the pressure in some container and the atmospheric pressure outside the container:



$$P_{\text{gauge}} = P - P_{\text{atm}} \tag{12.2}$$

where $P_{\text{atm}} = 1.0\ \text{atm} = 1.0 \times 10^5\ \text{N/m}^2$.

We are continually immersed in a fluid—the gaseous atmosphere. What is the magnitude of the force that the air exerts on one side of your body?

QUANTITATIVE EXERCISE 12.1 **The force that air exerts on your body**

Estimate the total force that air exerts on the front side of your body, assuming that the pressure of the atmosphere is constant.

Represent mathematically To calculate the total force exerted by air on the front of your body, multiply your front surface area by $10^5\ \text{N/m}^2$, the atmospheric air pressure. To estimate the surface area of the front of your body, model your body as a rectangular box—your height times your width. Assume a height of 1.8 m and a width of 0.3 m. Use Eq. (12.1) to estimate the force:

$$F_{\text{A on F}} = P \cdot A$$

Solve and evaluate $F_{\text{A on F}} = P \cdot A = (10^5\ \text{N/m}^2)[(1.8\ \text{m})(0.3\ \text{m})] \approx 5 \times 10^4\ \text{N}$. That's $5 \times 10^4\ \text{N} \times 0.22\ \text{lb/N} = 1.1 \times 10^4\ \text{lb}$, or 10,000 lb. So why aren't you immediately thrown backward? (Hint: Think about the force that the air behind you is exerting on you as well.)

Try it yourself What is the minimum force that you must exert to lift a 10 cm × 20 cm 0.10-kg rubber sheet that is stuck flat to a tabletop? Assume that there is no air below the sheet.

Answer $F_{\text{Y on S}} = (P \cdot A) + mg = (10^5\ \text{N/m}^2)[(0.10\ \text{m})(0.20\ \text{m})] + (0.10\ \text{kg})(9.8\ \text{N/kg}) = 2000\ \text{N}$, or about 450 lb. Since it is not really this difficult (although it is not easy!) to lift a rubber sheet off the table, under real circumstances there must be a small amount of air trapped between the rubber sheet and the table, exerting an additional upward force on the sheet.

Density

The quantity *mass* helps describe solid objects that have discrete real boundaries—a person, a car, or a ball. However, air is all around us. We can't see it, and it doesn't have well-defined boundaries. If we used the quantity mass to describe air, would it be the mass of one molecule of air, the mass of the air in a room, the mass of air over the street to a certain height, or something else? It's difficult to visualize air as a macroscopic object. For gases, a much more useful physical quantity is the mass of one unit of volume—volumetric mass density, or simply **density**.

Density measures the mass of one cubic meter of a substance. For example, at sea level and 0 °C, the mass of $1.0\ \text{m}^3$ of air is 1.3 kg. We say that the density of air is $1.3\ \text{kg/m}^3$. If we had $2.0\ \text{m}^3$ of air at sea level, its mass would be 2.6 kg. Its density is still $1.3\ \text{kg/m}^3$, since

$$\frac{2.6\ \text{kg}}{2.0\ \text{m}^3} = 1.3\ \text{kg/m}^3$$

Density ρ The density ρ (lowercase Greek letter "rho") of a substance or of an object equals the ratio of the mass m of a volume V of the substance (for example, air or water) divided by that volume V:

$$\rho = \frac{m}{V} \tag{12.3}$$

The unit of density is kg/m^3.

TIP Density is different from mass. Air in a room has a particular mass and density. If you divide the room into two equal parts using a screen, the mass of air in each part will be half the total mass, but the density in each part will remain the same.

QUANTITATIVE EXERCISE 12.2 The density of a person

Estimate the average density of a person.

Represent mathematically Assume the following about the person: mass is 80 kg; dimensions are 1.8 m tall, 0.3 m wide, and 0.1 m thick; and volume is $V \approx 1.8\ \text{m} \times 0.3\ \text{m} \times 0.1\ \text{m} = 0.054\ \text{m}^3$.

The person's average density is

$$\rho = \frac{m}{V}$$

Solve and evaluate Substitute the person's mass and volume into the above to get

$$\rho = \frac{80\ \text{kg}}{0.054\ \text{m}^3} = 1500\ \text{kg/m}^3$$

This is the correct unit for density. In Chapter 13, you will learn how to decide whether this is a reasonable estimate.

Try it yourself An iron ball with radius 5.0 cm has a mass of 2.0 kg. Determine the ball's average density. Explain your answer.

Answer The density of the ball is $3800\ \text{kg/m}^3$, much less than the 7860-kg/m^3 density of iron. The ball must be hollow.

Mass and size of particles

In 1811, an Italian scientist named Amedeo Avogadro proposed that equal volumes of different types of gas, when at the same temperature and pressure, contain the same number of gas particles. Using Avogadro's hypothesis, scientists could determine the relative masses of different types of particles by comparing the masses of equal volumes of the gases. Presently, scientists use Avogadro's number N_A to indicate the number of atoms or molecules present in 22.4 L (22.4×10^3 cm^3) of any gas at 0° C and standard atmospheric pressure.

The mass in grams of any substance that has exactly Avogadro's number of particles is equal to the **atomic mass** listed in the periodic table of chemical elements. For example, the atomic mass of molecular hydrogen is 2, that of molecular oxygen is 32, and that of lead is 207; therefore, 2 g of molecular hydrogen, 32 g of molecular oxygen, and 207 g of lead all have the same number of particles—exactly $N_A = 6.02 \times 10^{23}$. This number of particles is called a **mole** (Figure 12.10).

FIGURE 12.10 A mole (6×10^{23} particles) of helium (4 g of helium in the balloon), water (18 g), and salt (58 g).

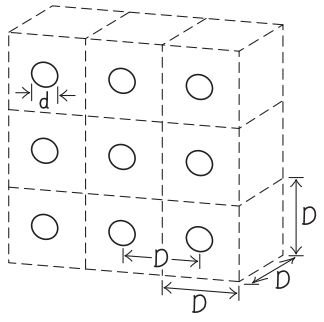
Avogadro's number and the mole Avogadro's number $N_A = 6.02 \times 10^{23}$ particles is called a mole. The number of particles in a mole is the same for all substances and is the number of particles whose total mass in grams is equal in magnitude to the molecular mass as measured in atomic mass units.

The mass of one mole of particles of any substance is called **molar mass**. One mole of hydrogen (H_2) has a mass of 2.0 g, one mole of oxygen (O_2) has a mass of 32 g, and one mole of lead has a mass of 207 g.

We can now easily determine the mass of a single gas particle of any substance by dividing the molar mass of the substance by 6.02×10^{23}, the number of particles in one mole of the substance:

$$m_{\text{particle}} = \frac{m_{\text{mole}}}{N_A}$$

We find that air (typically 70% N_2 with $m_{N_2} = 28$ g, 29% O_2 with $m_{O_2} = 32$ g, and small percentages of other gases) has a molar mass of about 29 g. Thus, the mass per air particle is approximately



$$m_{\text{air particle}} = \frac{29 \times 10^{-3}\,\text{kg}}{6.02 \times 10^{23}\,\text{air particles}} = 4.8 \times 10^{-26}\,\text{kg/air particle}$$

In addition to a particle's mass, its size is also important. The size of particles was estimated much later than the mass—in the 1860s by Josef Loschmidt. Loschmidt found the linear size of the particles that made up gases, liquids, and solids to be about $d \approx 10^{-9}$ m $= 10^{-7}$ cm $= 1$ nm. Contemporary methods indicate that the size of nitrogen and oxygen particles is about 0.3 nm.

EXAMPLE 12.3 The average distance between air particles

What is the average separation between nearby gas particles in the air, and how does it compare to the size of the particles themselves?

Sketch and translate Sketch the situation as a mole of air divided into equal-sized cubes as shown at the right, with one particle located at the center of each cube. The diameter of an individual particle is d; the average distance between them is D.

Simplify and diagram Assume standard conditions, with one mole of gas particles occupying a volume of $22.4 \times 10^3\ \text{cm}^3$. Now, imagine this volume divided equally between the particles (the cubes in the figure) and each particle being contained in a cube whose volume is D^3.

Represent mathematically We determine the volume of the cube corresponding to each particle and then take the cube root of that volume to estimate the average distance between them.

$$V_{\text{per particle}} = \frac{V_{\text{one mole}}}{N_{\text{particles in a mole}}}$$

$$D = \sqrt[3]{V_{\text{per particle}}} = \sqrt[3]{\frac{V_{\text{one mole}}}{N_{\text{particles in a mole}}}}$$

Solve and evaluate

$$D = \sqrt[3]{\frac{V_{\text{one mole}}}{N_{\text{particles in a mole}}}} = \sqrt[3]{\frac{22.4 \times 10^3\ \text{cm}^3}{6.02 \times 10^{23}\ \text{particles}}}$$

$$= \sqrt[3]{3.72 \times 10^{-20}\ \text{cm}^3/\text{particle}} = \sqrt[3]{37.2 \times 10^{-21}\ \text{cm}^3/\text{particle}}$$

$$= 3.34 \times 10^{-7}\ \text{cm}$$

Recall that the average diameter of a single particle of air is 3×10^{-8} cm. Thus, the approximate distance between the particles of air is on average

$$\frac{3.34 \times 10^{-7}\ \text{cm}}{3 \times 10^{-8}\ \text{cm}} \approx 10 \text{ times the size of the particles } (D/d = 10).$$

This is a lot of empty space. A macroscopic analogy would be two apples separated by about four feet. The empty space between the apples compared to the apple size is similar to the empty space between the particles of air compared to their size.

Try it yourself Estimate the distance between water molecules in liquid water and compare this distance to their dimensions. The density of water is $1.0 \times 10^3\ \text{kg/m}^3$. The molar mass of water is $18 \times 10^{-3}\ \text{kg/mole}$.

Answer The volume occupied by one mole of water is about

$$V_{\text{one mole}} \approx \frac{(18\ \text{g})(10^{-3}\ \text{kg/g})}{1000\ \text{kg/m}^3} = 18 \times 10^{-6}\ \text{m}^3$$

The volume occupied by one molecule is

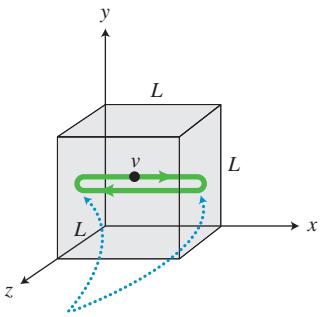
$$V_{\text{one molecule}} \approx \frac{18 \times 10^{-6}\ \text{m}^3}{6 \times 10^{23}} = 3 \times 10^{-29}\ \text{m}^3$$

The distance between particles is $D \approx 3 \times 10^{-8}$ cm. This is just a little larger than the size of the molecules, which means there is very little space between the water molecules.

REVIEW QUESTION 12.2 The distance between air particles is very small—about 3×10^{-7} cm. How can we say that there is considerable empty space in air?

12.3 Quantitative analysis of an ideal gas

We can use the quantities pressure, density, and the mole to construct a mathematical description of an ideal gas that will allow us to make predictions about new phenomena.



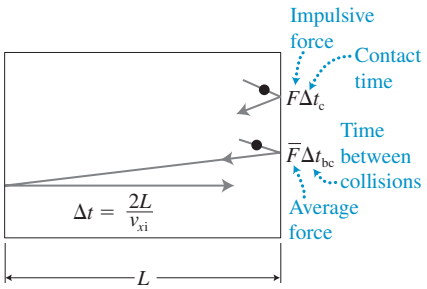
To start, we make a few more simplifying assumptions. First, in addition to modeling the particles (atoms or molecules) as point-like objects whose motion is governed by Newton's laws, assume that the particles do not collide with each other—they only collide with the walls of the container, exerting pressure on the walls (in other words, they move like the model depicted in Figure 12.6 but with no particle collisions). This is a reasonable assumption for a gas of low density. Second, assume that the collisions of particles with the walls are elastic. This makes sense, as the pressure of the gas in a closed container remains constant, which would not happen if the particles' kinetic energy decreased during inelastic collisions.

Now, let's construct a mathematical description of an ideal gas. Imagine the gas inside a cubic container with sides of length L (see **Figure 12.11**). A particle moves at velocity $\vec{v}$ with respect to a vertical wall. When it hits the wall, the wall exerts a force on the particle that causes it to reverse direction. Since the kinetic energy of the particle is the same before and after the collision, the same is true for its speed. The wall exerts a force on the particle, and the particle in turn exerts an equal-magnitude and oppositely directed force on the wall (Newton's third law).

Let's use impulse-momentum ideas to analyze the particle–wall collision. During the collision with the right wall, it exerts a normal force on the particle in the negative x-direction. Before the collision, the particle has a positive x-component of velocity v_{xi}. After the collision, the particle has a negative x-component of velocity v_{xf}. The impulse-momentum equation gives

$$mv_{xi} + F_{\text{W on P}\,x}\,\Delta t_c = mv_{xf}$$

FIGURE 12.11 A gas particle bouncing back and forth between the walls of a container.



Particle speed is the same before and after these elastic collisions.

Because the particle's speed is the same before and after the collision, $v_{xf} = -v_{xi}$. In addition, because of Newton's third law, $F_{\text{W on P}\,x} = -F_{\text{P on W}\,x}$. Thus,

$$mv_{xi} + (-F_{\text{P on W}\,x}\,\Delta t) = -mv_{xi}$$
$$2mv_{xi} = F_{\text{P on W}\,x}\,\Delta t_c$$

In the above equation, $F_{\text{P on W}\,x}$ is the impulsive force that the particle exerts on the wall during the very short time interval Δt that the particle is actually touching and colliding with the wall. How can we determine an average effect of these impulsive collisions in order to determine the pressure of the gas on the wall? We rewrite the right side of the equation as the product of the *average force* exerted by the particle on the wall from one collision to the next, multiplied by the time that *passes between collisions*. Note that this average force is much smaller than the impulsive force, since most of the time the particle is flying through the container and is not in contact with the wall (**Figure 12.12**). However, the time interval between collisions is longer than the impulsive time interval. The product of the big impulsive force and short time interval equals the product of the small average force and the long time interval between collisions.

FIGURE 12.12 A method to find the average force of particles colliding with the container wall.

The impulsive force exerted by a particle on the wall during the short contact time interval equals the average force exerted by the particle against the wall during the long time interval between collisions: $F\Delta t_c = \bar{F}\Delta t_{bc}$.

Looking at the x-component of the motion of the particle, we see that the time interval between collisions with the wall is $\Delta t_{bc} = (2L/v_{xi})$ since the particle must travel a distance $2L$ in the x-direction before colliding with the same wall again. So our equation becomes

$$2mv_{xi} = F_{\text{P on W}\,x}\,\Delta t_c = \bar{F}_{\text{P on W}\,x}\,\Delta t_{bc} = \bar{F}_{\text{P on W}\,x}\frac{2L}{v_{xi}}$$

The bar above the force in the last two expressions indicates that it is the *average force* exerted over the time interval between collisions. Multiplying by v_{xi} and dividing by 2 gives

$$mv_{xi}^2 = \bar{F}_{\text{P on W}\,x}L$$

To relate this microscopic relationship to macroscopic quantities, such as the pressure of the gas and its volume, multiply both sides of the equation by N, the number of particles of gas in the container:

$$Nmv_{xi}^2 = N\bar{F}_{\text{P on W}\,x}L$$

Because the particles do not all move with the same speed, we also replace the quantity v_{xi}^2 (the square of the x-component of the velocity of an individual particle) with its average value for all the particles:

$$Nm\bar{v}_x^2 = N\bar{F}_{\text{P on W}\,x}L$$

and then multiply both sides of the equation by L^2/L^2:

$$Nm\bar{v}_x^2 = \left(N\frac{\bar{F}_{\text{P on W}\,x}}{L^2}\right)L^3$$

The term in parentheses is the pressure exerted by the gas on the wall (the force exerted by all N particles divided by the wall area L^2.) The L^3 outside the bracket is the volume occupied by the gas. Thus, the above equation becomes

$$Nm\bar{v}_x^2 = PV$$

Note that this equation refers only to the motion of the particles along the x-direction. The particles also move in the y- and z-directions. Those equations are

$$Nm\bar{v}_y^2 = PV$$
$$Nm\bar{v}_z^2 = PV$$

To make an equation that simultaneously takes into account the motion of the particles in all three directions, we just add these three equations:

$$Nm(\bar{v}_x^2 + \bar{v}_y^2 + \bar{v}_z^2) = 3PV$$

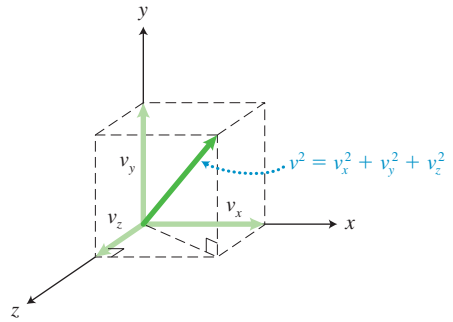
How does the sum $\bar{v}_x^2 + \bar{v}_y^2 + \bar{v}_z^2$ relate to $\bar{v}^2$, the average of the squared speed of a particle? We can think of the square of the speed of any particle at any time as the sum of components of velocity along the three axes: $v^2 = v_x^2 + v_y^2 + v_z^2$ (using the

geometrical argument in **Figure 12.13**). These components are independent of each other; this means that the average of the right side of the above v^2 equation over time is simply the sum of the averages: $\bar{v}^2 = \bar{v}_x^2 + \bar{v}_y^2 + \bar{v}_z^2$. Because all directions are equivalent, the average of the square of a particle's velocity in the x-direction is the same as in any other direction: $\bar{v}_x^2 = \bar{v}_y^2 = \bar{v}_z^2$. Therefore, $\bar{v}_x^2 = \frac{1}{3}\bar{v}^2$. Using this new average of the squared speed, we can write

$$Nm\bar{v}^2 = 3PV$$

The left side of the equation is the average kinetic energy of the particles if we multiply by $\frac{1}{2}$. After multiplying by $\frac{1}{2}$ and rearranging the equation, we get

$$PV = \frac{2}{3}N\left(\frac{1}{2}m\bar{v}^2\right) = \frac{2}{3}N\bar{K}$$



Dividing by V, we get

$$P = \frac{2}{3}\left(\frac{N}{V}\right)\left(\frac{1}{2}m\bar{v}^2\right) \tag{12.4}$$

When the particles have high speed, they (1) hit the walls of the container more frequently and (2) exert a greater force during the collisions. Both factors lead to a greater pressure. Thus, it is the speed squared and not just the speed of the particles that affects the pressure.

Suppose the number of particles N and the average of the squared speed of a particle $\bar{v}^2$ remain the same, but the volume of the box decreases. Then the pressure must increase. This seems reasonable. The smaller the container, the more frequently particles collide with the walls, and the greater the pressure. A unit analysis with a little manipulation indicates that both sides of Eq. (12.4) have the units $\mathrm{kg}/(\mathrm{m}\cdot\mathrm{s}^2)$, so the equation checks out from the point of view of dimensional analysis.

FIGURE 12.13 Using the Pythagorean theorem, we can relate the square of the speed of an individual particle at an arbitrary time to the squares of the x-, y-, and z-components of velocity.

TIP Every time you derive a new equation, ask yourself whether it makes sense. In Eq. (12.4), the pressure is proportional to the average squared speed of the particles. This means that doubling the speed of all the particles quadruples the pressure. Try to explain this dependence before you read on.

QUANTITATIVE EXERCISE 12.4 How fast do they move?

Estimate the average speed of air particles at standard conditions, when the air is at atmospheric pressure ($1.0 \times 10^5\ \mathrm{N/m^2}$), and one mole of the air particles (6.02×10^{23} molecules) occupies 22.4 L or $22.4 \times 10^{-3}\ \mathrm{m^3}$. Although air is composed of many types of particles, we will assume that the air particles have an average mass $m_{\mathrm{air}} = 4.8 \times 10^{-26}\ \mathrm{kg/particle}$.

Represent mathematically We can estimate the average speed using Eq. (12.4):

$$P = \frac{2}{3}\left(\frac{N}{V}\right)\left(\frac{1}{2}m_p\bar{v}^2\right)$$

Solve and evaluate Multiply both sides by $3V$, divide by Nm_{p}, and take the square root to get

$$\bar{v} = \sqrt{\frac{3PV}{Nm_{\mathrm{p}}}}$$

Inserting the appropriate values gives

$$\bar{v} = \sqrt{\frac{3PV}{Nm_{\mathrm{p}}}} = \sqrt{\frac{3(1.0 \times 10^5\ \mathrm{N/m^2})(22.4 \times 10^{-3}\ \mathrm{m^3})}{(6.02 \times 10^{23})(4.8 \times 10^{-26}\ \mathrm{kg})}} = 480\ \mathrm{m/s}$$

This number seems very high. We know that it takes several minutes for the smell of perfume to propagate across a room. How could it take so long if the perfume molecules move at hundreds of meters per second (about 1000 mph)? We will find out in the next section.

Try it yourself The pressure in a diver's full oxygen tank is about $4 \times 10^7\ \mathrm{N/m^2}$. What happens to the average speed of the particles when some of the oxygen is used up and the pressure in the tank drops to half this value? What assumptions did you make?

Answer If we assume that the only change is in the number of particles in the tank, then their average speed should stay the same. However, when a gas expands (as this one does when the valve to the tank is opened), the gas inside the tank has to push outward against the environment in order to leave the tank. This requires energy, which lowers the average kinetic energy (and therefore the speed) of the particles inside.

We will learn later that the speed we calculated in Exercise 12.4 has a special name—it is called the *root mean square* speed, or *rms* speed.

Time interval between collisions

We estimated that the average speed of air particles is $v = 480\ \text{m/s}$, or about 1000 mph. Then why does it take 5 to 10 minutes for the smell of perfume to travel across a room? Remember that we estimated that the average distance between particles in a gas at normal conditions is about $D = 3.3 \times 10^{-7}$ cm. While deriving our mathematical descriptions of the ideal gas model, we assumed that the particles do not collide with each other. Perhaps the gas particles actually do collide with neighboring particles and change direction due to each collision, thus making little progress in crossing the room. More detailed estimates show that particles collide about 10^9 times a second under typical atmospheric conditions. They change direction at each collision, and even though they are moving very fast, their migration from one place to another is very slow.

REVIEW QUESTION 12.3 In the expression $PV = \frac{1}{3}N(m_p\bar{v}^2)$, pressure is proportional to the particle mass times the average squared speed of the particles. Thus, doubling the average speed of particles leads to quadrupling the pressure. Explain why this makes sense.

12.4 Temperature

So far, we have said nothing about the temperature of the gas. Could there be a connection between the temperature of a gas and the average kinetic energy of its particles? We now consider this idea.

As with other physical quantities, temperature can be measured. A common way to measure temperature is with a liquid thermometer. A liquid thermometer consists of a narrow tube connected to a bulb at the bottom (**Figure 12.14**). The bulb and part of the tube are filled with a liquid that expands predictably when heated and shrinks when cooled. To calibrate a thermometer, one marks the height of the liquid at the freezing and boiling conditions of water and then divides this interval by a set number of degrees. On the Celsius scale, 100 °C separates the boiling point and freezing point of water. On the Fahrenheit scale, 180 °F separates these same points (212 °F for boiling and 32 °F for freezing). We'll discuss the Kelvin scale shortly.

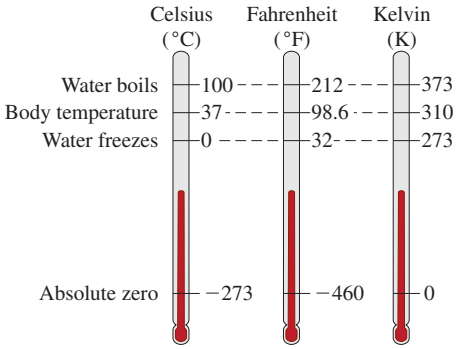


FIGURE 12.14 Thermometers calibrated for (a) Celsius scale, (b) Fahrenheit scale, and (c) absolute (Kelvin) scale.

What does temperature really quantify?

We measure the temperature of an object indirectly by measuring the changing volume of a liquid that contacts the object. But what is actually different about an object at higher temperature compared to an object at lower temperature? Consider the following experiments.

Imagine you have kept your inflated beach ball in a cold garage in the winter. When you pick it up, it feels soft and looks a little wrinkly. You then bring it into your warm house, and it suddenly becomes firmer and bouncier. If you take it back to the garage, it becomes soft and wrinkly again. Assuming that the air pressure inside the house and garage is the same, the particles of air inside the ball must exert a higher pressure when the gas inside the ball gets warmer and a lower pressure when the gas inside the ball gets colder. Changing the temperature of the gas therefore seems to change its pressure.

How can we explain that a warmer gas seems to exert a greater pressure on its container? We can hypothesize that the particles in the warm gas exert a greater impulsive force on the container because they are moving faster, and therefore in addition to exerting a greater force during every collision, they collide more frequently with the container walls. Conversely, the particles in a cooler gas exert a smaller force on their container's walls because they are moving more slowly and colliding less frequently. Based on this reasoning, we can hypothesize that the temperature of a gas is related to

the speed of the random motion of its particles. Is the temperature of the gas related to any other properties of the gas (the pressure or volume of the gas, or perhaps how many particles comprise the gas and how massive they are)?

Let's do more formal observational experiments. We place three different gases in three containers of different but known volumes. A pressure gauge measures the pressure inside each container. The number N of particles (atoms or molecules) in each container is determined by measuring the mass of the gas m_{gas} in each container and then calculating

$$N = \frac{m_{\text{gas}}}{m_{\text{molar mass}}} N_{\text{A}}$$

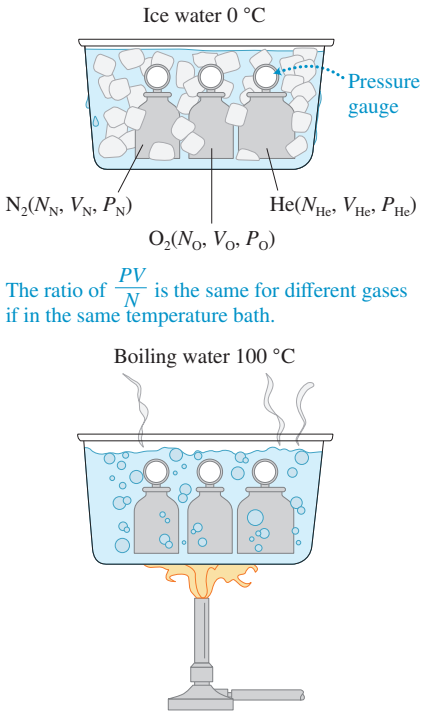
where N_{A} is Avogadro's number. Each container, with known V, P, and N for each gas, is placed first in an ice water bath and then in boiling water, as depicted in **Figure 12.15**. Notice that the volume, pressure, and the number of particles in each container are different, but the temperature of the matter in the three containers is the same. Collected data show the following pattern: independently of the type of gas in a container, the ratio PV/N is identical for all of the gases in the containers when they are at the same temperature:

$$\frac{P_{\text{N}}V_{\text{N}}}{N_{\text{N}}} = \frac{P_{\text{O}}V_{\text{O}}}{N_{\text{O}}} = \frac{P_{\text{He}}V_{\text{He}}}{N_{\text{He}}}$$

The ratio for the gases in the containers at $T_1 = 0\ ^\circ\text{C}$ is smaller than that for the gases in the containers at $T_2 = 100\ ^\circ\text{C}$.

From these experiments we can conclude that if you have any amount of a particular type of gas and know its pressure, volume, and the number of particles, then the ratio PV/N only depends on the temperature of the gas. Maybe it equals the temperature? Consider the units of this quantity:

$$\frac{(\text{N/m}^2)\text{m}^3}{\text{particle}} = \frac{\text{N} \cdot \text{m}}{\text{particle}} = \text{J/particle}$$



The joule is a unit of energy, not temperature! Perhaps gas particles at the same temperature have the same average energy per particle. Remember that in the ideal gas model, the particles do not have any potential energy between them. This suggests that temperature is related to the average kinetic energy per particle of the gas.

Can we mathematically relate the energy per particle of the gas molecules to the temperature of the gas? The simplest relationship is a direct proportionality to the temperature:

$$\frac{PV}{N} = k_{\text{B}}T \tag{12.5}$$

where k_{B} is a proportionality constant whose value we need to determine (you'll see shortly why we are using the subscript B). Notice that this relationship immediately leads to a difficulty. The kinetic energy per particle is always a positive number. But in the Celsius and Fahrenheit scales, temperatures can have negative values. So the particle energy cannot be proportional to temperature if measured using either of those scales.

FIGURE 12.15 The ratio PV/N seems to depend only on the gas temperature.

Absolute (Kelvin) temperature scale and the ideal gas law

We need a scale in which the zero point is the lowest possible temperature. That way, all temperatures will be positive. This lowest possible temperature can be found by applying Eq. (12.5) to measurements with a container of gas at two different reference temperatures—the freezing and boiling temperatures of water. The data in **Table 12.4** on the next page were collected when a constant volume metal container with 1 mol

of nitrogen ($N = N_A = 6.02 \times 10^{23}$ particles) was placed in baths at two different temperatures. If we assume that the ratio PV/N is proportional to the absolute temperature of the gas, we can find the coefficient of proportionality.

TABLE 12.4 PV/N for one mole of gas in a 22.4-L container at two different temperatures

Conditions in the bath	Pressure	Volume	$\frac{PV}{N} = k_B T$
Ice water (T)	$1.013 \times 10^5\ \text{N/m}^2$	$22.42 \times 10^{-3}\ \text{m}^3$	$3.773 \times 10^{-21}\ \text{J}$
Boiling water ($T + 100$)	$1.384 \times 10^5\ \text{N/m}^2$	$22.42 \times 10^{-3}\ \text{m}^3$	$5.154 \times 10^{-21}\ \text{J}$

We now have two equations with two unknowns: the constant k_B and the water temperature T on the new scale.

$$3.773 \times 10^{-21}\ \text{J} = k_B T$$
$$5.154 \times 10^{-21}\ \text{J} = k_B(T + 100)$$

We subtract the first equation from the second to get $k_B = 1.38 \times 10^{-23}\ \text{J/degree}$. The freezing temperature T of the water is then

$$T = \frac{3.773 \times 10^{-21}\ \text{J}}{k_B} = \frac{3.773 \times 10^{-21}\ \text{J}}{1.381 \times 10^{-23}\ \text{J/degree}} = 273.2\ \text{degrees}$$

On this new scale, water freezes at $T = 273.2$ degrees above the lowest possible temperature. The lowest possible temperature on the new scale is 0 and on the Celsius scale should be −273.2 °C. Considerable modern research has refined this value to −273.15 °C. This temperature scale is called the absolute temperature scale or the Kelvin scale (because it was invented by William Thomson (Lord Kelvin) in 1848). Temperatures are described in kelvin (see the right scale in Figure 12.14). Temperature intervals on the Kelvin scale are the same as on the Celsius scale: a change in temperature of 1 C° is equivalent to a change in temperature of 1 K. Celsius temperatures are related to kelvin as follows:

$$T_K = T_C + 273.15 \tag{12.6}$$

In other words, a temperature of 273.15 K is equivalent to 0 °C.

The constant k_B that we determined using the data in Table 12.4 is called **Boltzmann's constant** after the German physicist Ludwig Boltzmann (1844–1906):

$$k_B = 1.38 \times 10^{-23}\ \text{J/K}$$

Temperature conversions

$T_F = (9/5)T_C + 32°$

$T_C = (5/9)(T_F - 32°)$

$T_K = T_C + 273.15°$

TIP Note that Eq. (12.7) implies that when the absolute temperature of the ideal gas is zero, its pressure must be zero.

We can now rewrite Eq. (12.5) using the absolute temperature T and the value of the constant k_B:

$$PV = Nk_B T \tag{12.7}$$

Equation (12.7) is called **the ideal gas law**. It is also commonly used in a slightly different form. Rather than referring to the number of particles that comprise the gas (typically an extremely large number), we refer to the number n of moles of the gas. Since one mole has Avogadro's number of particles, $N = nN_A$. Substituting this into Eq. (12.7), we get

$$PV = nN_A k_B T$$

The product of the two constants $N_A k_B$ is another constant called the **universal gas constant** R. Equation (12.7) then becomes

$$PV = nRT \tag{12.8}$$

where $R = N_A k_B = \left(6.02 \times 10^{23}\ \frac{\text{particles}}{\text{mole}}\right)\left(1.38 \times 10^{-23}\ \frac{\text{J}}{\text{K}}\right) = 8.3\ \frac{\text{J}}{\text{K} \cdot \text{mole}}$

This is the more common form of the ideal gas law.

Ideal gas law For an ideal gas, the quantities pressure P, volume V, number of particles N, temperature T (in kelvins), and Boltzmann's constant $k_B = 1.38 \times 10^{-23}$ J/K are related in the following way:

$$PV = Nk_BT \tag{12.7}$$

The law can also be written in terms of the number of moles n, and the universal gas constant $R = 8.3 \dfrac{\text{J}}{\text{K} \cdot \text{mole}}$:

$$PV = nRT \tag{12.8}$$

Temperature and particle motion

Let us look back at what we have done so far. First, we found the relation between the pressure and volume of an ideal gas and the average kinetic energy of the particles that comprise it, $PV = \frac{2}{3}N\overline{K}$ [Eq. (12.4)]. This was a reasonable finding: the faster the particles move inside the gas, the more often and the harder they hit the walls. The particle mass and the number of them per unit volume N/V also affect the pressure.

Next, we found that the product of the pressure and volume of a gas is related to the temperature of the gas, $PV = Nk_BT$ [Eq. (12.7)]. We can now connect the average kinetic energy of the gas particles to the absolute temperature of the gas. Rearrange Eqs. (12.4) and (12.5) so they each have PV/N on the left side. Insert the average kinetic energy $\overline{K} = \frac{1}{2}m\overline{v}^2$ in the right side of Eq. (12.4) and then set the right sides of the two equations equal to each other to get

$$\overline{K} = \tfrac{3}{2}k_BT \tag{12.9}$$

The temperature of a gas is an indication of the average random translational kinetic energy of the particles in the ideal gas. Note that temperature is an indication of not only the particle's speed but also its kinetic energy—the mass of the particle also matters. One implication of this discovery is that when you have a mixture of particles of different gases in one container (for example, in air there are nitrogen molecules, oxygen molecules, carbon dioxide molecules, etc.), the lighter molecules move faster than the heavier ones, though each species of particles has the same average kinetic energy (since each species will have the same temperature once the gas has mixed together thoroughly).

Before we move to an example, let's think more about temperature. Imagine that you have two metal containers with identical gases that have been sitting in the same room for a long time. One container is large and the other one is small. Which one has the higher temperature? Since the average kinetic energy per particle is the same in each container, the temperatures of the two gases are the same. However, the total kinetic energy of the particles in the large container is larger because it contains more particles.

Imagine another scenario: you have two containers with the same type of gas. In one container the gas is hot, and in the other it is cold. What will happen if you mix those two gases together? The faster moving particles of the hot gas will collide with the slower moving particles of the cold gas. If we use the laws of momentum and kinetic energy conservation (assuming that collisions are elastic), we find that following a collision, the faster moving particle on average is moving slower than before the collision, and the slower particle is on average moving faster than before. Eventually, the particles of the two gases have the same average kinetic energy and therefore the same temperature. Physicists say that the gases are in *thermal equilibrium.*

TIP Only when temperature is measured in kelvins can Eq. (12.9) be used to calculate the average kinetic energy of the particles.

Using Eq. (12.9) we can determine the square root of the average speed squared of gas particles $\sqrt{\bar{v}^2}$, called the root-mean-square speed, or **rms speed**:

$$\bar{K} = \tfrac{1}{2}m\bar{v}^2 = \tfrac{3}{2}k_B T$$

$$\Rightarrow \sqrt{\bar{v}^2} = \sqrt{\frac{3k_B T}{m}} \tag{12.10}$$

Calculating rms speeds of particles allows us to estimate quantities involved in gas processes.

QUANTITATIVE EXERCISE 12.5 **Comparing speeds for the same temperature**

Two different gases (gas 1 has particles of mass m_1, and gas 2 has less massive particles, of mass m_2) are at the same temperature. How do the rms speeds of their particles compare?

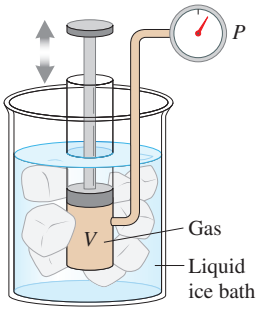
Represent mathematically Because the gases are at the same temperature, their particles have the same average kinetic energy (Eq. 12.9):

$$\bar{K} = \tfrac{3}{2}k_B T$$

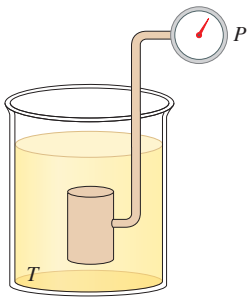
Therefore, their rms speeds are $\sqrt{\bar{v}^2} = \sqrt{\dfrac{3k_B T}{m}}$.

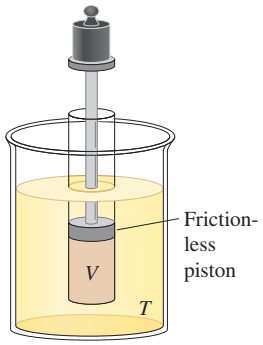
Solve and evaluate For gas 1, $\sqrt{\bar{v}_1^2} = \sqrt{\dfrac{3k_B T}{m_1}}$; for gas 2, $\sqrt{\bar{v}_2^2} = \sqrt{\dfrac{3k_B T}{m_2}}$. The ratio of the rms speeds is

$$\frac{\sqrt{\bar{v}_1^2}}{\sqrt{\bar{v}_2^2}} = \frac{\sqrt{m_2}}{\sqrt{m_1}}$$



The ratio of the rms speeds is the inverse ratio of the square roots of their masses. Therefore, the molecules of smaller mass move faster at the same temperature.





REVIEW QUESTION 12.4 Ken says that the temperature of a gas measured in kelvins is the average kinetic energy of the gas particles. Do you agree with him? Support your answer with an explanation.

12.5 Testing the ideal gas law

In order to determine if the ideal gas law describes the behavior of real gases, we will use the law to predict the outcomes of some testing experiments. If the predictions match the outcomes, we gain confidence in the ideal gas law. In the experiments below we will keep one of the variables (T, V, or P) constant and predict the relation between the two other variables. Processes in which T, V, or P are constant are called **isoprocesses**. The three types of isoprocesses we will investigate are **isothermal** (T = constant), **isochoric** (V = constant), and **isobaric** (P = constant).

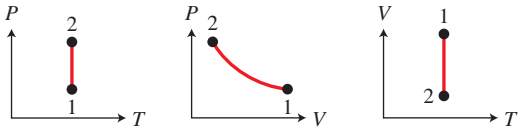
TESTING EXPERIMENT TABLE 12.5 **Does the ideal gas law apply to real gases?**

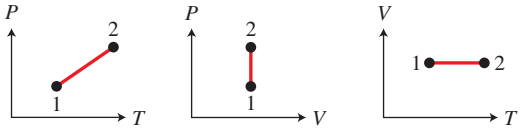
Testing experiment	Prediction	Outcome
Experiment 1: Isothermal process. n moles of gas are in a variable volume V container that is held in an ice bath at constant 0 °C (273 K) temperature T. How does the pressure of the gas change as we change the volume of the container? We push the piston slowly so that the temperature of the gas is always the same as the ice bath. 	According to the ideal gas law $PV = nRT$, during a constant temperature process, the product of PV should remain constant. We predict that as the volume decreases, the pressure will increase so that the product remains constant.	Data collected: $V(\mathrm{m}^3)$ — $P(\mathrm{N/m}^2)$ 3.0×10^{-4} — 2.0×10^{5} 6.0×10^{-4} — 1.0×10^{5} 9.0×10^{-4} — 0.67×10^{5} The product of volume and pressure remains constant in all experiments.

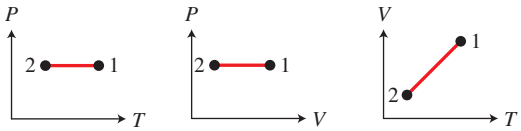
Testing experiment	Prediction	Outcome
Experiment 2: Isochoric process. n moles of gas and the gas volume V are kept constant. The container is placed in different-temperature baths. How does the gas pressure change as the temperature changes? 	According to the ideal gas law $PV = nRT$, during a constant volume process, the ratio $\frac{P}{T} = \frac{nR}{V}$ should remain constant. We predict that the pressure should increase in proportion to the temperature.	Data collected: T(K) — P(N/m^2) 300 — 1.00×10^5 350 — 1.17×10^5 400 — 1.33×10^5 The ratio of pressure and temperature is constant in all experiments.
Experiment 3: Isobaric process. n moles of gas and the gas pressure P are held constant, as a frictionless piston in the gas container can move freely up and down keeping the pressure constant. The pressure inside the container is the sum of the constant atmospheric pressure and the pressure exerted by the object on top of the piston. How does the gas volume change as the temperature changes? 	According to the ideal gas law $PV = nRT$, during a constant pressure process, the ratio $\frac{V}{T} = \frac{nR}{P}$ should remain constant. We predict that the volume should increase in proportion to the temperature.	Data collected: T(K) — V(m^3) 300 — 3.0×10^{-4} 350 — 3.5×10^{-4} 400 — 4.0×10^{-4} The ratio of volume and temperature remains constant in all experiments.

Conclusion

The outcomes of all three experiments are consistent with the predictions.







- In the first experiment, the product of pressure and volume remains constant, as predicted.
- In the second experiment, the pressure increases in direct proportion to the temperature, as predicted.
- In the third experiment, the volume increases in direct proportion to the temperature, as predicted.

The outcomes of the experiments in Testing Experiment Table 12.5 were consistent with predictions based on the ideal gas law, giving us increased confidence that the law applies to real gases in the range of temperatures and pressures used in the experiments (however, we cannot say that we proved it). A summary of gas processes (some of which are not isoprocesses) is provided in Table 12.6, on the next page.

Reflection on the process of construction of knowledge

Let's pause here and reflect on the process through which we arrived at the mathematical version of the ideal gas law. The first step was to construct a simplified model of a system that could represent a real gas—the ideal gas model. This involved making assumptions about the internal structure of gases. This model was based on some observations and also on the knowledge of particle motion and interactions developed earlier—Newton's laws of motion. We used this model to devise a mathematical description of the behavior of gases, the ideal gas law. We then tested its applicability to real gases by using it to predict how macroscopic quantities describing the gas (temperature, pressure, volume, and the amount of gas) would change during specific processes (isothermal, isobaric, and isochoric) and used the ideal gas law to construct equations that described those processes. These predictions were consistent with the outcomes of the new testing experiments.

TABLE 12.6 A summary of ideal gas law processes

Name	Constant quantities	Changing quantities	Equation	Graphical representations
Isothermal	N or n, T	P, V	$PV = \text{constant}$ $P_1V_1 = P_2V_2$	
Isochoric	N or n, V	P, T	$\frac{P}{T} = \text{constant}$ $\frac{P_1}{T_1} = \frac{P_2}{T_2}$	
Isobaric	N or n, P	V, T	$\frac{V}{T} = \text{constant}$ $\frac{V_1}{T_1} = \frac{V_2}{T_2}$	
[No name]	N or n	P, V, T	$\frac{PV}{T} = \text{constant}$ $\frac{P_1V_1}{T_1} = \frac{P_2V_2}{T_2}$	
[No name]		P, V, T, N or n	$\frac{PV}{NT} = k_B$ $\frac{PV}{nT} = R$	

The process of constructing the knowledge described above looks relatively smooth and straightforward—observe, simplify, explain, test. However, in real physics, knowledge construction is not that simple and straightforward. For example, the isoprocesses mentioned above were known in physics long before the ideal gas model was constructed. They were discovered in the 17th and 18th centuries and carried the names of the people who discovered them through patterns found in observational experiments. The relation $PV = \text{constant}$ for constant temperature processes is called **Boyle's law** and was discovered experimentally by Robert Boyle in 1662. The relation $V/T = \text{constant}$ for constant pressure processes is called **Charles's law** and was discovered by Jacques Charles in 1787, though the work was published by Joseph Gay-Lussac only in 1802. Gay-Lussac also discovered the relation $P/T = \text{constant}$, now called **Gay-Lussac's law**. When these relations were discovered empirically, there was no explanation for why gases behaved in these ways. The explanations arrived much later via the ideal gas model. The real process of knowledge construction is often more complicated and nonlinear than how it is presented in a textbook. The skills you are learning by constructing knowledge through experimentation will prepare you for those more complicated situations.

Applications of the ideal gas law

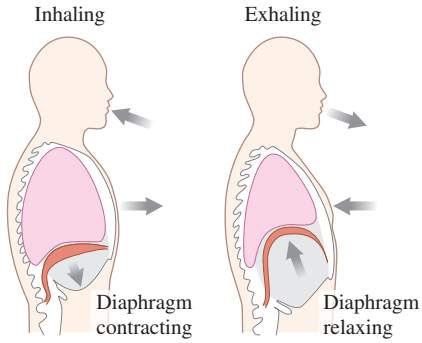
The ideal gas law has numerous everyday applications. Try to explain the following phenomena using the ideal gas law. Clearly state your assumptions.

- A sealed, half-full plastic bottle of water shrinks when placed in the refrigerator.
- A refrigerator's door is difficult to open again right after you opened and closed it the first time.
- A bubble of gas expands as it rises from the bottom of a lake.
- Air rushes into your lungs when your diaphragm, a dome-shaped membrane, contracts.

Below we consider in greater detail two of these phenomena.

Breathing During inhalation, our lungs absorb oxygen from the air, and during exhalation, they release carbon dioxide, a metabolic waste product. Yet the lungs have no muscle to push air in or out. The muscle that makes inhaling and exhaling possible, the diaphragm, is not part of the lungs. The diaphragm is a large, dome-shaped muscle that separates the rib cage from the abdominal cavity (see **Figure 12.16**).

The diaphragm works like a bellows. As the diaphragm contracts and moves down from the base of the ribs, the volume of the chest cavity and lungs increases. If we assume that for a brief instant both the temperature and the number of particles are constant (an isothermal process),



$$P = \frac{nRT}{V}$$

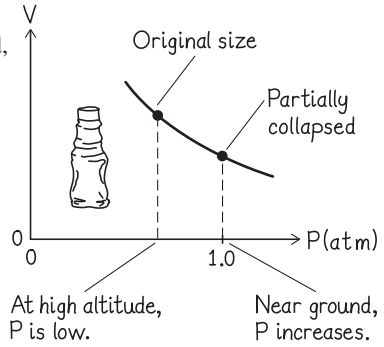
then the pressure in the cavity and in the lungs will decrease. The pressure of the outside air is greater than that of the inside. Because of this, the outside air at normal atmospheric pressure enters the mouth or nostrils and fills the lungs with fresh new air (an increase $\Delta n > 0$ of the amount of air). During exhalation, the opposite occurs. The diaphragm relaxes and rises, decreasing the volume of the chest cavity and the lungs, thus increasing the pressure inside (again assuming that for a brief instant both the temperature and the number of particles are constant),

$$P = \frac{nRT}{V}$$

Because the inside pressure is higher than the outside pressure, air is then forced out of the lungs.

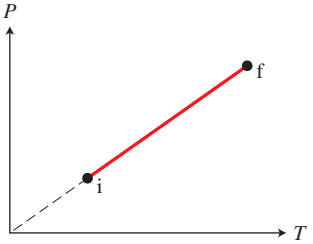
FIGURE 12.16 The diaphragm is a large, dome-shaped muscle that separates the rib cage from the abdominal cavity. Relaxing or contracting the diaphragm changes the volume of the lungs and chest cavity.

Diaphragm contraction and relaxation cause air to enter and leave the lungs.



Your water bottle on an airplane The behavior of an empty plastic water bottle on an airplane is another example of an isothermal process.

CONCEPTUAL EXERCISE 12.6 A shrunk bottle



On a flight from New York to Los Angeles you drink all of a bottle of water, close the cap, and then store it in your seat pocket. You take it out right after landing. The bottle has changed shape; it looks like someone crushed it. How can we explain this shape change?

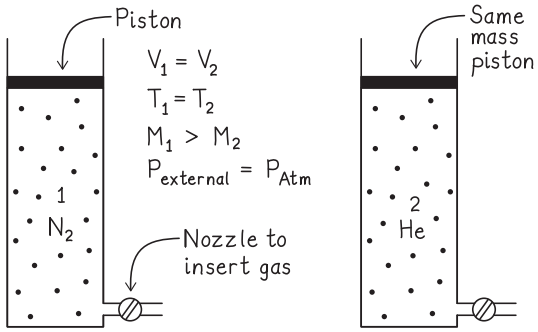
Sketch and translate The bottle's volume decreased, though the temperature in the cabin didn't change much during the flight.

Simplify and diagram If we assume the bottle was perfectly sealed, and the temperature of the gas inside the bottle remained constant, then we can model the process as an isothermal process, represented graphically in the figure below. Although the cabin is pressurized, at higher elevations air pressure and air density inside the cabin are less than at lower elevations. You closed the bottle when it was filled with low-density air at high elevation. As the plane descended, the air density and pressure inside the cabin increased. More air particles were hitting the outside walls of the empty bottle than were hitting the inside. The higher pressure from outside partially crushed the bottle. If you open the cap after landing, the bottle will pop back to its original shape.

Try it yourself A different process is represented on a graph at right. Describe the process in words. Assume the mass to be constant.

Answer The graph represents an isochoric process. The graph line, if extended, passes through the origin; thus the pressure is directly proportional to temperature. The gas was in a sealed container. The gas container was first placed in a water bath at low temperature and then transferred to a water bath at high temperature. The volume of the gas is constant. The pressure increases as the particles move faster and collide with the walls of the container more often.

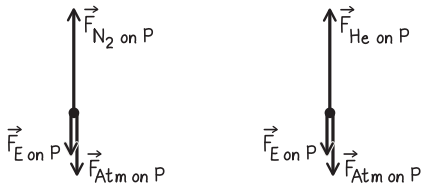
Comparing different gases



How does the type of gas that is in a container affect the pressure of the gas? Consider the next Conceptual Exercise.

CONCEPTUAL EXERCISE 12.7 **Analyzing two types of gas**

You have two containers, both with pistons of equal mass that can move up and down depending on the pressure of the gas below. Each container has a nozzle that allows you to add gases to the containers. Container 1 holds nitrogen (molar mass M_1); we label its volume V_1. Container 2 (V_2) holds helium (molar mass $M_2 < M_1$). The volumes are the same ($V_1 = V_2$), and the containers sit in the same room. What physical quantities describing the gases inside the two containers can we compare?



Sketch and translate We sketch the situation in the figure below. Quantities that we can try to compare between the two containers are the following:

(a) the pressure inside the containers
(b) the average kinetic energy of a particle of each type of gas
(c) the mass of individual gas particles
(d) the rms speed of the particles in each container
(e) the number of particles in each container
(f) the mass of the gas in each container
(g) the density of the gas in the containers

Simplify and diagram Assume that the ideal gas model accurately describes the gases.

(a) Consider the pressures inside the containers by analyzing the identical movable pistons above the gases. Force diagrams for both pistons are shown at above right. Earth exerts a downward force $\vec{F}_{\text{E on P}}$ on the piston, the atmospheric gas above a piston pushes down on the piston $\vec{F}_{\text{Atm on P}}$, and the gases inside the containers push up on their pistons $\vec{F}_{\text{N}_2\text{ on P}}$ or $\vec{F}_{\text{He on P}}$. As the pistons are not accelerating, the net force exerted on each is zero. Because the downward forces exerted by Earth and by the outside atmospheric air on each piston are the same, the upward forces exerted by the gases in each container on the piston must also be the same. Since the surface areas of the two pistons are the same, the pressure of the gas inside each container must be the same, $P_{\text{N}_2} = P_{\text{He}}$.

The downward forces on each piston are the same, so the upward force is also the same.

(b) Since the temperature of a gas depends only on the average kinetic energy of the particles, and the temperature of the two gases is the same, the average kinetic energy of each particle is the same:

$$\frac{3}{2}k_{\text{B}}T = \frac{1}{2}m_{\text{N}_2\text{ in }1}\bar{v}^2_{\text{N}_2\text{ in }1} = \frac{1}{2}m_{\text{He in }2}\bar{v}^2_{\text{He in }2}$$

(c) and (d) Since the N_2 particles in gas 1 have a higher molar mass than the He particles in gas 2, the N_2 molecular mass $m = M_1/N_{\text{A}}$ is also the higher mass ($m_{\text{N}_2\text{ in }1} > m_{\text{He in }2}$). Using this result and that from (b), we find that $\bar{v}^2_{\text{N}_2\text{ in }1} < \bar{v}^2_{\text{He in }2}$. The more massive particles move slower.

(e) The pressure, volume, and temperature are the same for both gases. Thus, according to the ideal gas law, both gases have the same number of particles and the same number of moles of gas in their containers ($PV/k_{\text{B}}T = N$; $PV/RT = n$).

(f) and (g) Since the mass of a nitrogen molecule is greater than the mass of a helium atom, and there are equal numbers of particles in each container, the total mass of the gas in the nitrogen container must be greater than the total mass of the gas in the helium container ($M_{\text{N}_2\text{ in }1} > M_{\text{He in }2}$). Since the volumes of the containers are equal, the density $\rho = M/V$ of the gas in the nitrogen container must be greater than that in the helium container ($\rho_{\text{N}_2\text{ in }1} > \rho_{\text{He in }2}$).

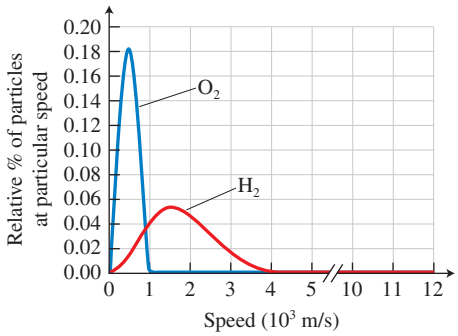
Try it yourself Why are the gases at the same temperature?

Answer Both containers sit in the same room temperature environment.

REVIEW QUESTION 12.5 What is the difference between the following two equations: $PV = \frac{1}{3}Nm\bar{v}^2$ and $PV = nRT$?

12.6 Speed distribution of particles

In our previous analysis, we defined the rms speed of gas atoms or molecules:



$$v_{\text{rms}} = \sqrt{\bar{v}^2} = \sqrt{\frac{3k_{\text{B}}T}{m}} \tag{12.10}$$

We found that for air molecules at room temperature, the rms speed was about 500 m/s. When we derived relationships such as these, we assumed for simplicity that gas particles do not collide with each other, just with the walls of a container. However, we know that if gas particles did not collide, the smells of food and perfume would spread at hundreds of meters per second—almost instantly. The smells spread slowly, so the particles must be colliding. What happens if we no longer ignore collisions of particles with each other?

Maxwell speed distribution

In 1860 James Clerk Maxwell included the collisions of the particles in his calculations involving an ideal gas. This inclusion led to the following prediction: at a particular temperature, the collisions of gas particles with each other cause a very specific distribution of speeds. When we were deriving Eq. (12.4) we assumed that the speeds of the particles were different, but we did not have any idea of why they were different. Maxwell's work explained this variability of speeds by the collisions of the particles with each other. Consider the red H_2 line (hydrogen atoms) in **Figure 12.17**. On the vertical axis, we plot the percentage of particles that have a particular speed. According to Maxwell, a certain percentage of the particles should have speeds around 1000 m/s, but the most around 1500 m/s, and fewer at higher speeds. Very few particles have extremely low or extremely high speeds. Most should have intermediate speeds. The most probable speed is at the highest point on the curve in Figure 12.17. Surprisingly, the rms speed of the particles at a particular temperature is the same as that predicted by the model with no collisions—Eq. (12.10).

FIGURE 12.17 The Maxwell particle speed distributions at a particular temperature for two gases.

Maxwell's distribution of molecular speeds allows us to explain some very interesting observational evidence. You know that our atmosphere contains molecules of oxygen, nitrogen, carbon dioxide, water, and so forth, but it has almost no hydrogen molecules. Why is there so little free hydrogen in the Earth's atmosphere? Recall from Chapter 7 that every planet has a specific value of escape speed—the speed that an object needs to have to escape the gravitational pull of that planet. For Earth, this speed is about 11 km/s = 11,000 m/s. In Quantitative Exercise 12.4 we estimated the rms speed of an air molecule to be about 480 m/s. The most probable molecular speed according to Maxwell's distribution is a little smaller. We also know that the lighter the molecules, the faster they move at the same temperature. Assuming that a hydrogen molecule is about 15 times less massive than an average air molecule, we can say that its rms speed at the same temperature should be about 4 times higher (see the reasoning in Quantitative Exercise 12.5), but it is still much smaller than the escape speed. Based on this estimate, we should have an atmosphere full of hydrogen molecules. What is wrong with our reasoning?

We did not take into account the *shape* of Maxwell's distribution of molecular speeds (Figure 12.17). The tail of the distribution shows that there are molecules with a speed that is much faster than the most probable speed. These molecules might escape. As soon as the fastest molecules leave, more molecules, colliding with other molecules, might acquire the speeds in the tail of the distribution and leave, too. This process will repeat until almost all light molecules are gone. Is this reasoning correct? Surely there are some oxygen or nitrogen molecules that have very high speeds—why don't they eventually escape? It turns out that the answer lies in the word *probability*. The likelihood (or probability) of the escape of a hydrogen molecule at 10 °C (50 °F) is 300 orders of magnitude higher than that for the molecules of oxygen or nitrogen. It is the interplay between escape speed (gravitational interaction) and the Maxwell distribution of molecular speeds (gas processes) during the 4.6-billion-year history of our solar system that determines what kind of atmosphere a particular planet has.

Limitations of the ideal gas law

Isoprocesses were discovered empirically with experiments long before the model of an ideal gas was constructed. However, the fact that the ideal gas law predicts those empirical results is evidence that the law itself and the ideal gas model on which the law is based can be applied to real gases in certain conditions (although real gases are made of molecules that have internal structure and the ideal gas model assumes point-like particles). Nevertheless, the ideal gas law has limitations.

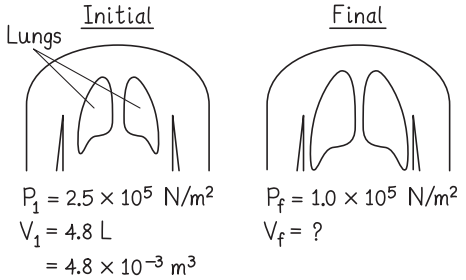
For real gases such as air, the measurements of pressure and volume at the conditions of normal pressure ($1.0 \times 10^5\ \mathrm{N/m^2}$, as elsewhere) and temperature (room temperature) are consistent with predictions of the ideal gas law. But at very high pressures or very low temperatures, real measurements differ from those predictions (for example, the ideal gas law does not predict that one can turn a gas into a liquid). The ideal gas law describes gases accurately only over certain temperature and pressure ranges.

REVIEW QUESTION 12.6 Why do we need the term "probability" when we explain the absence of free hydrogen in Earth's atmosphere?

12.7 Skills for analyzing processes using the ideal gas law

In this section, we adapt our problem-solving strategy to analyze gas processes. A general strategy for analyzing such processes is described on the left side of the table in Example 12.8 and illustrated on the right side for a specific process.

PROBLEM-SOLVING STRATEGY 12.1 Applying the ideal gas law



Sketch and translate

- Sketch the process. Choose a system and describe the initial and final states of the system.
- Label the knowns and the unknowns on the sketch.
- Describe the process (a word description of the changes in the system between the initial and final states) in terms of macroscopic quantities (pressure, volume, temperature, moles of gas).

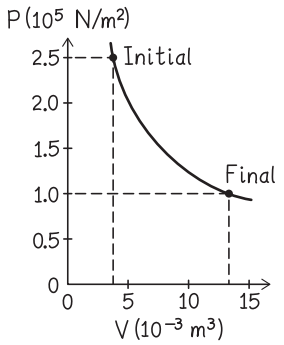
EXAMPLE 12.8 Scuba diver returns to the surface

The pressure of the air in a scuba diver's lungs when she is 15 m under the water surface is $2.5 \times 10^5\ \mathrm{N/m^2}$ (equal to the pressure of the water at that depth), and the air occupies a volume of 4.8 L. Determine the volume of the air in the diver's lungs when she reaches the surface, where the pressure is $1.0 \times 10^5\ \mathrm{N/m^2}$.

The gas inside the diver's lungs is the system. The initial state of the system is when the diver is underwater; the final state is when she is at the surface. As the diver swims upward, the pressure of the system decreases and its volume increases.

Simplify and diagram

- Decide if the system can be modeled as an ideal gas.
- Decide which macroscopic quantities remain constant and which do not.
- If helpful, draw P vs. V, P vs. T, and/or V vs. T graphs to represent the process.



Represent mathematically

Use your sketch or the graphs to help construct a mathematical description—some version of the ideal gas law.

Solve and evaluate

- Solve for the unknowns.
- Evaluate the answer: is it reasonable? (For example, evaluate the magnitude of the answer, its units, and how the solution behaves in limiting cases.)

Assume that the gas inside the lungs can be modeled as an ideal gas. Assume that the diver does not exhale, which means that the moles of gas remain constant. Assume the temperature of the gas is constant at body temperature. A pressure-versus-volume graph for the process is shown at right.

$$P_i V_i = P_f V_f \Rightarrow V_f = \frac{P_i V_i}{P_f}$$

$$V_f = \frac{P_i V_i}{P_f} = \frac{(2.5 \times 10^5\ \text{N/m}^2)(4.8 \times 10^{-3}\ \text{m}^3)}{(1.0 \times 10^5\ \text{N/m}^2)} = 12 \times 10^{-3}\ \text{m}^3$$

We found the lung volume to be 12 L, much larger than seems possible. Is the answer realistic? Remember that we assumed that the mass of the gas inside remains constant—the diver does not exhale. As we see from the solution, it is important for divers to exhale as they are ascending and the gas expands. If not, they can suffer severe internal damage.

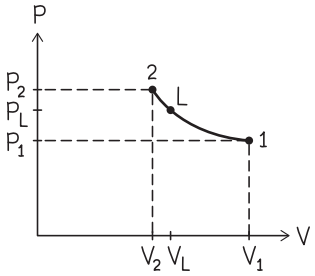
Try it yourself How many moles of gas are in the diver's lungs and how many should she exhale so the final volume is only 6 L instead of 12? Assume that the gas temperature is 37 °C.

Answer 0.47 moles; 0.23 moles.

TIP Notice that the graph lines for isobaric processes (constant pressure) pass through the origin in V-versus-T graphs and those for isochoric (constant volume) processes pass through the origin in P-versus-T graphs.

EXAMPLE 12.9 Further investigation of an airplane bottle

In Conceptual Exercise 12.6 you qualitatively investigated the behavior of a plastic bottle on a long flight. On your next long flight, you decide to investigate the shrinking bottle phenomenon quantitatively. In the middle of the flight you open a bottle (Figure a) and then close it again. When you land, you observe that the bottle shrinks (Figure b). You take the closed bottle home, turn it upside down into a bowl of water (Figure c), and open it. The bottle expands to its normal size, letting 150 mL of water into the bottle (Figure d). You measure the total volume of the bottle to be 550 mL. Use this information to estimate the pressure in the airplane cabin.



(CONTINUED)

Sketch and translate The air inside the bottle is the system. The initial state is when you open the bottle on the cruising airplane. The air fills the whole bottle ($V_1 = 550$ mL) at the pressure inside the airplane (P_1). When the plane lands, the volume decreases to V_L (the bottle is crushed) and the pressure inside the bottle increases to P_L. The L state is an intermediate state in the process. The final state is when you open the bottle at home and water is let in. The volume of air in the bottle is now $V_2 = 550$ mL $-$ 150 mL $= 400$ mL. The pressure inside is P_2. We need to determine the pressure P_1. We already know why the bottle shrinks when the plane lands. But why does the water enter the bottle? Even though the atmospheric air crushes the bottle, the pressure inside is probably still less than atmospheric due to the semiflexible walls of the bottle that tend to return the bottle to the original shape. When the bottle is opened under the water, the pressure difference pushes water into the bottle. In addition, the bottle expands, returning to its original shape, which helps let water into the bottle. This process stops when the pressure of the air in the bottle is equal to the atmospheric pressure outside the bottle. Thus $P_2 = P_{atm}$.

Simplify and diagram We assume that the temperature in the airplane was the same as at your home ($T_1 = T_2$). Thus the process is isothermal. We can represent the process that the gas in the bottle went through with the P-versus-V graph at right.

Represent mathematically We can now express the graphical representation with an equation for an isothermal process: $P_1V_1 = P_2V_2$. Dividing both sides by V_1 we get $P_1 = P_2 \dfrac{V_2}{V_1}$. Now we see that we do not need to convert ml of volume into m^3 because the units for volume cancel.

Solve and evaluate

$$P_1 = P_2 \frac{V_2}{V_1} = (1.0 \times 10^5\ \mathrm{N/m^2}) \frac{400\ \mathrm{mL}}{550\ \mathrm{mL}} = 0.73 \times 10^5\ \mathrm{N/m^2}$$

The result seems reasonable: the pressure during flight is lower than the atmospheric pressure at the ground.

Try it yourself Your sister happens to measure the temperature while you are performing the experiments on the airplane and at home. Her data are $T_{flight} = 80$ °F and $T_{home} = 67$ °F. Use her data to improve your previous estimation of the pressure during the flight.

Answer $0.75 \times 10^5\ \mathrm{N/m^2}$.

REVIEW QUESTION 12.7 Why is it helpful to know whether the mass of the gas is constant during a particular process?

12.8 Thermal energy, the Sun, and diffusion

We've seen that the ideal gas model can be applied to many real-world situations as long the gas particles do not interact with each other (they are far apart and/or the pressure and temperature are not extreme). In this section we will look at two more everyday phenomena: the Sun shining and gas diffusion. In order to get started, we need to quantify something for gases that we've only discussed qualitatively in the textbook so far: thermal energy.

We learned in Chapter 7 that thermal energy is the component of the internal energy of a system that is associated with temperature. We know from Eq. (12.9) that the temperature of an ideal gas is determined by the average kinetic energy $\overline{K}$ of its randomly moving particles. We can now therefore define the gas's **internal thermal energy** or just **thermal energy,** U_{th}, as the sum of all the individual particles' kinetic energies. This is equal to $N\overline{K}$, where N is the number of particles. Using Eq. (12.9), this gives

$$U_{th} = N\left(\tfrac{3}{2}k_B T\right)$$

How long can the Sun shine?

The thermal energy of gases can be used to help analyze many kinds of systems, such as automobile engines, Earth's atmosphere, and the Sun. The mass of the Sun is about 2×10^{30} kg, its radius is about 7×10^8 m, and the temperature of the Sun's surface is

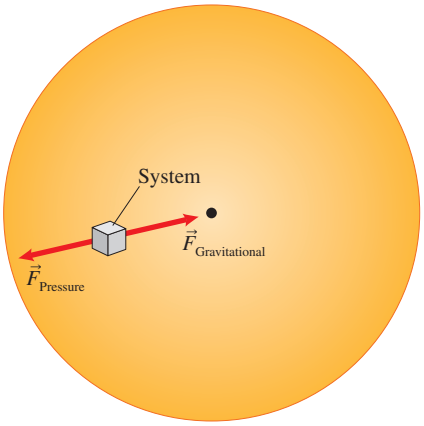
about 6×10^3 K. Its core temperature is about 10^7 K. Every second, the Sun radiates about 4×10^{26} J as visible light and other forms of radiation. How long can our Sun shine if its particles possess *only* thermal energy?

We first need to determine how much thermal energy the Sun possesses. Then we can divide this amount of energy by the amount it loses every second from the emission of visible light and other forms of radiation to find the number of seconds the Sun can shine if its thermal energy is the only source of this radiative energy. Although in reality there are some complications with modeling the material of the Sun as an ideal gas, we will do so in this case for simplicity.

To estimate the thermal energy of the Sun, we need to know the number of particles and the average temperature of these particles. The Sun consists mostly of hydrogen atoms. To find the number of hydrogen atoms in the Sun, we estimate the number of moles of hydrogen gas and then multiply by the number of particles in one mole (note that 1 mole of hydrogen has a mass of 1 g $= 10^{-3}$ kg):

$$N = \frac{m_{\text{Sun}}}{m_{\text{hydrogen atom}}} = \frac{m_{\text{Sun}}}{M_{\text{molar mass hydrogen}}/N_{\text{A}}}$$

$$= \frac{(2 \times 10^{30}\,\text{kg})}{(10^{-3}\,\text{kg/mole})/(6 \times 10^{23}\,\text{particles/mole})}$$



$$= \frac{(2 \times 10^{30}\,\text{kg})}{(1.7 \times 10^{-27}\,\text{kg/particle})} = 12 \times 10^{56}\,\text{particles}$$

At the very high temperatures within the Sun, each hydrogen atom separates into two smaller particles called an electron and a proton—subjects of later study. This separation of hydrogen atoms doubles the number of particles to 24×10^{56}. We can show that the average distance between these particles is much greater than their dimensions, and thus we can apply the ideal gas model to the Sun's material.

These particles do not spread out into space or collapse in toward the center of the Sun because two competing forces remain in balance. All parts of the Sun exert a gravitational force on all other parts. If we select a small volume inside the Sun as the system of interest and add the forces that all other particles of the Sun exert on the system (see **Figure 12.18**), the net gravitational force points toward the center of the Sun. The second force exerted on the system is the pressure force exerted by other particles on the system. This force points outward and balances the gravitational force. As long as these forces balance each other, the Sun is in equilibrium and does not expand or collapse.

FIGURE 12.18 Gas in the Sun is in equilibrium due to two forces.

This small volume of gas (the system) is kept in equilibrium by the gravitational force and pressure force exerted on it by other particles in the Sun.

Now consider the total thermal energy of the Sun's particles for two extreme cases. A lower bound for the Sun's thermal energy assumes its temperature throughout equals its surface temperature. An upper bound for the Sun's thermal energy assumes its temperature throughout equals its core temperature.

$$U_{\text{th min}} = \tfrac{3}{2} N k_{\text{B}} T_{\text{min}}$$

$$= \tfrac{3}{2}(24 \times 10^{56}\,\text{particles})(1.38 \times 10^{-23}\,\text{J/K})(6 \times 10^3\,\text{K}) = 3 \times 10^{38}\,\text{J}$$

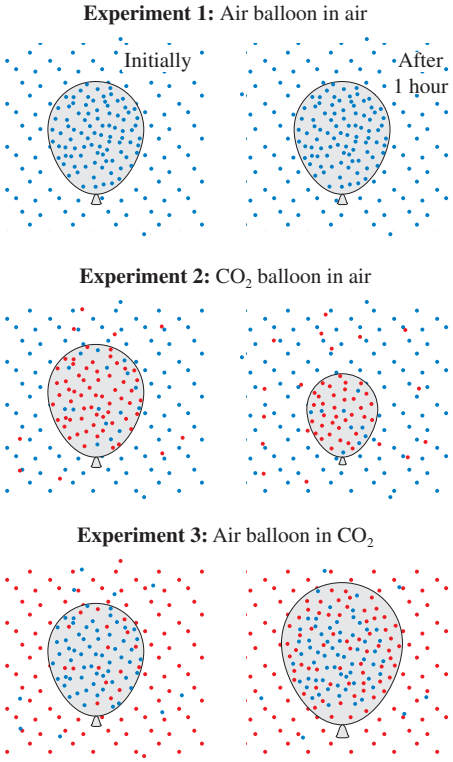
$$U_{\text{th max}} = \tfrac{3}{2} N k_{\text{B}} T_{\text{max}}$$

$$= \tfrac{3}{2}(24 \times 10^{56}\,\text{particles})(1.38 \times 10^{-23}\,\text{J/K})(10^7\,\text{K}) = 5 \times 10^{41}\,\text{J}$$

Both numbers are so large that they imply that the Sun will shine for a long time. The life expectancy of the Sun in seconds (based on the thermal energy alone) equals the total thermal energy divided by the energy radiated per second, $L = 4 \times 10^{26}$ J/s. We can convert our result to years, noting that there are about 3×10^7 s in 1 year.

$$\Delta t_{\text{min}} = \frac{E_{\text{min}}}{L} = \frac{3 \times 10^{38}\,\text{J}}{4 \times 10^{26}\,\text{J/s}} = 7.5 \times 10^{11}\,\text{s} = \frac{7.5 \times 10^{11}\,\text{s}}{3 \times 10^{7}\,\text{s/year}} = 2 \times 10^{4}\,\text{years}$$

$$\Delta t_{\text{max}} = \frac{E_{\text{max}}}{L} = \frac{5 \times 10^{41}\,\text{J}}{4 \times 10^{26}\,\text{J/s}} = 1.2 \times 10^{15}\,\text{s} = \frac{1.2 \times 10^{15}\,\text{s}}{3 \times 10^{7}\,\text{s/year}} = 4 \times 10^{7}\,\text{years}$$



The maximum possible lifetime for the Sun if it simply converts its thermal energy into light and other forms of radiation is 4×10^7 years, or 40 million years. Yet according to astronomical knowledge of stars and our solar system, the Sun has been shining in the same way for over 4 billion years. Thus this simple estimate suggests that either the Sun's material cannot be modeled as an ideal gas or some source of energy other than the thermal energy of the Sun's particles has been supporting its existence for a time interval equal to the age of Earth. As the ideal gas model explains many phenomena occurring on the Sun, it means that there must be another energy source within the Sun that far exceeds the thermal energy present. (We will learn about it in Chapter 29.)

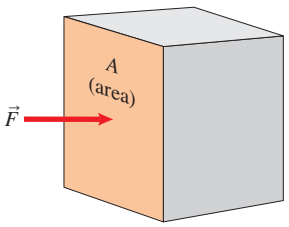
Diffusion

Imagine that you fill a balloon with air and leave it for one hour. The balloon looks the same; it did not change. You fill another balloon with carbon dioxide (CO_2); after one hour the balloon is significantly smaller. Why do the balloons look different?

One possible explanation is that the balloon rubber interacts differently with different molecules. If we hypothesize that CO_2 molecules can easily pass through it, but other molecules in air cannot, then we can create a simple model of the process. To indicate that CO_2 molecules interact differently with the balloon than other air molecules, we will represent CO_2 molecules with red dots and other air molecules (mostly nitrogen and oxygen) with blue dots (**Figure 12.19**). Blue dots cannot pass through the wall. They bounce off the wall either immediately or after some time. This happens to air molecules inside the first balloon (Experiment 1) and outside both balloons. Red dots inside the balloon in Experiment 2 move randomly inside the balloon and slowly migrate through the wall to the outer surface, where their concentration is smaller. They then leave the surface, traveling randomly in all directions.

FIGURE 12.19 Testing the model of air molecule movement through semipermeable balloons.

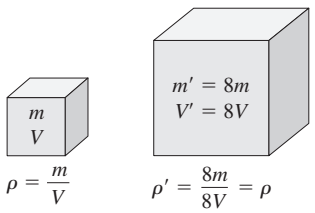
In our model, CO_2 molecules outside the balloon can as easily get into the balloon as get out of it, so why does CO_2 leak out? Remember that the concentration of CO_2 molecules inside the balloon is much higher than that outside. Many more CO_2 molecules leave the balloon than come back in (Experiment 2), while the air molecules from outside cannot get into the balloon at all. This imbalance in the behavior of different molecules explains why the balloon deflates.



We can test this explanation with another simple experiment. Place an air-filled balloon into a container filled with CO_2. If our explanation is correct, then the CO_2 molecules from outside the balloon should pass through the rubber into the balloon. Air molecules cannot get out of the balloon (Experiment 3). The balloon should therefore expand and eventually burst. This is exactly what happens!

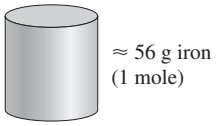
The process of molecules moving, due to their random motion, from a region of higher concentration to a region of lower concentration is called **diffusion**. The explanation of diffusion follows from the ideal gas model. Diffusion plays an important role in biological processes. Oxygen is carried by hemoglobin in the blood from the heart to the tiny capillary vessels spread throughout the body. Oxygen diffuses from the oxygen-rich blood inside the capillaries to the oxygen-poor cells near the capillaries. Some of these cells may be muscle fibers. Since a muscle fiber needs oxygen to twitch, the action of muscles may be limited by the rate of oxygen diffusion into the fiber. Thus, diffusion limits the rate of some processes in our bodies.

REVIEW QUESTION 12.8 How do we know that the Sun's thermal energy is not the main source of the light energy it produces?



Summary

Pressure P The perpendicular component of the force F that another solid object or a gas or liquid exerts perpendicular to a surface of area A divided by that area. (Section 12.2)



$$P = \frac{F_\perp}{A} \qquad \text{Eq. (12.1)}$$

Density ρ The mass m of a substance divided by the volume V that the substance occupies. (Section 12.2)

$$\rho = \frac{m}{V} \qquad \text{Eq. (12.3)}$$

Moles n and **Avogadro's number** N_A A mole of any type of particle equals Avogadro's number of that type of particle. Molar mass is the mass of one mole. (Section 12.2)

$$N_A = 6.02 \times 10^{23} \text{ particles/mole}$$

Temperature T and **temperature scales** Temperature measures how hot or cool a substance is. When measured in kelvins, the temperature is directly proportional to the average random kinetic energy of a particle in that substance. (Section 12.4)

The average kinetic energy per atom or molecule in a gas is

$$\overline{K} = \frac{3}{2}k_B T$$

$$T_F = (9/5)T_C + 32°$$
$$T_C = (5/9)(T_F - 32°)$$
$$T_K = T_C + 273.15° \qquad \text{Eq. (12.6)}$$

Thermal energy of an ideal gas U_{th} The sum of average kinetic energies of the particles of the ideal gas. (Section 12.8)

N particles in the system

$$U_{th} = N\left(\frac{3}{2}k_B T\right)$$

Ideal gas model and ideal gas law The ideal gas model is a simplified model of gas in which atoms/molecules are considered to be point-like objects that obey Newton's laws. They only interact with each other and with the walls of the container during collisions exerting pressure. The ideal gas law relates the macroscopic quantities of such a gas. (Sections 12.1, 12.3, 12.4, and 12.5)

$$P = \frac{2}{3}\left(\frac{N}{V}\right)\left(\frac{1}{2}m\bar{v}^2\right) \qquad \text{Eq. (12.4)}$$

$$PV = Nk_B T \qquad \text{Eq. (12.7)}$$

$$PV = nRT \qquad \text{Eq. (12.8)}$$

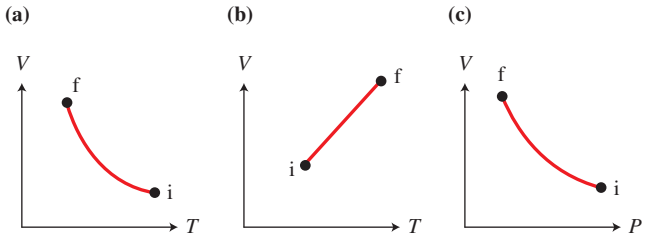
Assume that N, n, and P are constant. Then

$$\frac{V_1}{T_1} = \frac{V_2}{T_2} \qquad \text{(Isobaric)}$$

Assume that N, n, and V are constant. Then

$$\frac{P_1}{T_1} = \frac{P_2}{T_2} \qquad \text{(Isochoric)}$$

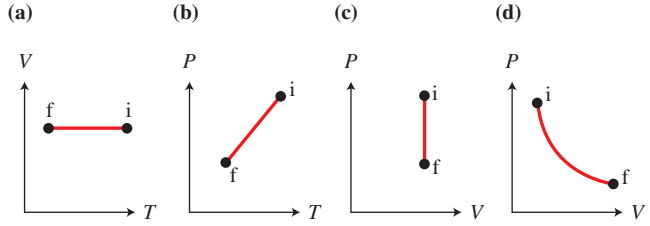
Assume that N, n, and T are constant. Then



$$P_1V_1 = P_2V_2 \qquad \text{(Isothermal)}$$

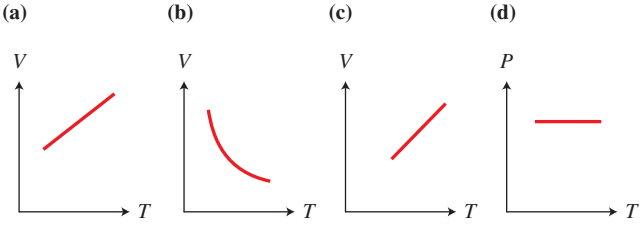
Questions

Multiple Choice Questions



1. What experimental evidence rejects the explanation that wet clothes become dry because the air absorbs the water?
   (a) The clothes dry faster if you blow air across them.
   (b) They do not dry if you put the wet clothes in a plastic bag.
   (c) The clothes dry faster under a vacuum jar with the air pumped out.
2. What is the difference between the words particle, molecule, and atom?
   (a) A particle is bigger than a molecule or an atom.
   (b) Particles can be microscopic and macroscopic, while atoms and molecules are only microscopic.
   (c) Molecules are made of atoms; both can be called particles.
   (d) All are correct.
   (e) Both b and c are correct.
3. You have a basketball filled with gas. Which method below changes its volume because of a mass change of the gas inside?
   (a) Put it into a refrigerator. (b) Squeeze it.
   (c) Pump more gas into it. (d) Hold it under water.
   (e) Leave it in the sunshine.
4. Choose the quantities describing the air inside a bike tire that do *not* change when you pump the tire.
   (a) Mass (b) Volume
   (c) Density (d) Pressure
   (e) Particle mass (f) Particle concentration
5. Which answer below does *not* explain the decrease in size of a basketball after you take it outside on a cold day?
   (a) The pressure inside the ball decreases.
   (b) The temperature of the gas inside the ball decreases.
   (c) The volume of the ball decreases.
   (d) The number of gas particles inside the ball decreases.
6. What causes balloons filled with helium to deflate as time passes?
   (a) The elasticity of the rubber decreases.
   (b) The temperature inside decreases.
   (c) The pressure outside the balloon increases.
   (d) The gas from inside diffuses into the atmosphere.
7. From the list below, choose the assumption that we did not use in deriving the ideal gas law.
   (a) Gas particles can be treated as objects with zero size.
   (b) The particles do not collide with each other inside the container.
   (c) The particles collide partially inelastically with the walls of the container.
   (d) The particles obey Newton's laws.
8. You have a mole of oranges. The mass of each orange is m. Imagine that you split each orange in half. What will be the molar mass of this pile of half oranges in kilograms?
   (a) $m/2$ (b) $m/(6.02 \times 10^{23})$
   (c) $2m/(6.02 \times 10^{23})$ (d) $(m/2)/(6.02 \times 10^{23})$
9. How might physicists have come to know that at a constant temperature and constant mass, the pressure of an ideal gas is inversely proportional to its volume?
   (a) They could have conducted an experiment maintaining the gas as described above and made a pressure-versus-volume graph.
   (b) They could have derived this relationship using the equations describing the ideal gas model and the relationship between the speed of the particles and the gas temperature.
   (c) Both a and b are correct.
10. A cylindrical container is filled with a gas. On the top of the container sits a heavy piston that is free to move (see the experimental setup in Table 12.5, Experiment 3). When the gas is heated, the piston moves up, causing the volume of the gas to increase. Which equation below best describes this process?
    (a) $V_{\text{initial}}/T_{\text{initial}} = V_{\text{final}}/T_{\text{final}}$
    (b) $P_{\text{initial}}V_{\text{initial}} = P_{\text{final}}V_{\text{final}}$
    (c) $P_{\text{initial}}V_{\text{initial}} = nRT_{\text{final}}$
    (d) $P_{\text{initial}}V_{\text{initial}} = Nk_{\text{B}}T_{\text{final}}$
11. A cylindrical container is filled with a gas. On the top of the container sits a heavy piston that is free to move. In a certain process, you observe that with constant external pressure pushing down on the piston, the piston moves up, causing the volume of the gas to increase. Which graph below best represents this process (**Figure Q12.11**)?

FIGURE Q12.11



12. A completely closed rigid container of gas is taken from the oven and placed in ice water. Which graph below does not represent this process (**Figure Q12.12**)?

FIGURE Q12.12

   (e) None of them do.
13. Which graph below does not represent a process described by the equation $V_{\text{initial}}/T_{\text{initial}} = V_{\text{final}}/T_{\text{final}}$ (**Figure Q12.13**)?

FIGURE Q12.13

   (e) a and b
14. What does contracting and relaxing the diaphragm allow?
    (a) Greater O_2 absorption by humans and mammals compared to other species
    (b) Greater pressure difference between air in the lungs and outside air
    (c) The only way to facilitate air intake into and out of the lungs
    (d) a and b
    (e) a, b, and c
15. When is air inhaled into the lungs?
    (a) When lung muscles cause them to expand
    (b) When the diaphragm contracts
    (c) When the chest expands
    (d) b and c
    (e) a, b, and c

16. Which of the following conditions are crucial for performing an isothermal compression of a gas (see the experimental setup in Table 12.5, Experiment 1)?
    (a) The piston should be moved very slowly.
    (b) There should be no friction between the piston and the gas container.
    (c) The gas container should be kept in a vertical position.
    (d) The volume of the gas container should be much smaller than the volume of the ice bath.

Conceptual Questions

17. (a) How do we know if a real gas can be described as an ideal gas? (b) How can you decide if air in the physics classroom can be described using the ideal gas model?
18. Why does it hurt to walk barefoot on gravel?
19. In the magic trick in which a person lies on a bed of nails, why doesn't the person get hurt by the nails?
20. What does it mean if the density of a gas is 1.29 kg/m^3?
21. How many oranges would you have if you had two moles of oranges?
22. Imagine that you have an unknown gas. What experiments do you need to do and what real equipment do you need to determine the mass of one molecule of this gas?
23. Describe how temperature and one degree are defined on the Celsius scale.
24. Describe how temperature and one degree are defined on the Kelvin scale.
25. Why does sugar dissolve faster in hot tea than in cold water?
26. (a) Describe experiments that were used to test the predictions of the molecular kinetic theory. (b) What experiments revealed its limitations?
27. Give three examples of diffusion that are important for human life.
28. Why do very light gases such as hydrogen not exist in Earth's atmosphere but do exist in the atmospheres of giant planets such as Uranus and Saturn?
29. Why does the Moon have no atmosphere? Explain.
30. Explain why Earth has almost no free hydrogen in its atmosphere.

Problems

Below, BIO indicates a problem with a biological or medical focus. Problems labeled EST ask you to estimate the answer to a quantitative problem rather than derive a specific answer. Asterisks indicate the level of difficulty of the problem. Problems with no * are considered to be the least difficult. A single * marks moderately difficult problems. Two ** indicate more difficult problems.

12.2 Pressure, density, and the mass of particles

1. What are the molar masses of molecular and atomic hydrogen, helium, oxygen, and nitrogen? What are their molecular masses?
2. EST Estimate the number of hydrogen atoms in the Sun. The mass of the Sun is 2×10^{30} kg. About 70% of it by mass is hydrogen, 30% is helium, and there is a negligible amount of other elements.
3. The average particle density in the Milky Way galaxy is about one particle per cubic centimeter. Express this number in SI units (kg/m^3). Indicate any assumptions you made.
4. * (a) What is the concentration (number per cubic meter) of the molecules in air at normal conditions? (b) What is the average distance between molecules compared to the dimensions of the molecules? (c) Can you consider air to be an ideal gas? Explain your answer.
5. * What is the mass of a water molecule in kilograms? What is the mass of an average air molecule in kilograms?
6. You find that the average gauge pressure in your car tires is about 35 psi. (a) How many newtons per square meter is it? What is gauge pressure? (b) Determine the absolute pressure in the tires.
7. BIO **Forced vital capacity** Physicians use a machine called a spirometer to measure the maximum amount of air a person can exhale (called the forced vital capacity). Suppose you can exhale 4.8 L. How many kilograms of air do you exhale? What assumptions did you make to answer the question? How do these assumptions affect the result?
8. A container is at rest with respect to a desk. Inside the container a particle is moving horizontally at a speed v with respect to the desk. It collides with a vertical wall of the container elastically and rebounds. Compare the direction and the speed of the particle if the wall is (a) at rest with respect to the desk; (b) moving in the same direction as the particle at a speed smaller than the particle's; and (c) moving in the direction opposite to the motion of the particle at a smaller speed.

12.3 Quantitative analysis of ideal gas

9. **Oxygen tank for mountains** Consider an oxygen tank for a mountain climbing trip. The mass of one molecule of oxygen is 5.3×10^{-26} kg. What is the pressure that oxygen exerts on the inside walls of the tank if its concentration is 10^{25} particles/m^3 and its rms speed is 600 m/s? What assumptions did you make?
10. You have five molecules with the following speeds: 300 m/s, 400 m/s, 500 m/s, 450 m/s, and 550 m/s. (a) What is their average speed? (b) What is their rms speed? Compare it with the average speed.
11. Two gases in different containers have the same concentration and same rms speed. The mass of a molecule of the first gas is twice the mass of a molecule of the second gas. What can you say about their pressures? Explain.
12. Four molecules are moving with the following velocities: 300 m/s south, 300 m/s north, 400 m/s east, and 400 m/s west. (a) What is their average velocity? (b) What is their rms speed?
13. * **Hitting tennis balls against a wall** A 0.058-kg tennis ball, traveling at 25 m/s, hits a wall, rebounds with the same speed in the opposite direction, and is hit again by another player, causing the ball to return to the wall at the same speed. The collision of the ball with the wall lasts 1 ms. The ball returns to the wall once every 0.60 s. (a) Determine the average force exerted on the ball during a single collision and the force that the ball exerts on the wall averaged over the time between collisions. State the assumptions that you made. (b) If 10 people are practicing against a wall with an area of 30 m^2, what is the average pressure of the 10 tennis balls against the wall?
14. * Friends throw snowballs at the wall of a 3.0 m × 6.0 m barn. The snowballs have mass 0.10 kg and hit the wall moving at an average speed of 6.0 m/s. They do not rebound. Determine the average pressure exerted by the snowballs on the wall if 40 snowballs hit the wall each second. Which problem, this or the previous problem, resembles the actions of the molecules of an ideal gas hitting the walls of their container?
15. * A ball moving at a speed of 3.0 m/s with respect to the ground hits a stationary wall at a 30° angle with respect to the surface of the wall. Determine the direction and the magnitude of the velocity of the ball after it rebounds. Explain carefully what physics principles you used to find the answer. What assumptions did you make? How will the answer change if one or more of them are not valid?
16. * **Oxygen tank for mountain climbing** An oxygen container used by mountain climbers has a 90-min oxygen supply at a rate of 6 L/min (with the volume measured at atmospheric pressure). Determine everything you can about the gas in the container. Make reasonable assumptions.

12.4 Temperature

17. Your temperature, when taken orally, is 98.6 °F. When taken under your arm, it's 36.6 °C. Are these results consistent? Explain.
18. Air consists of many different molecules, for example, N_2, O_2, H_2O, and CO_2. Which molecules are the fastest on average? The slowest on average? Explain.
19. What is the average kinetic energy of a particle of air at standard conditions?
20. Air is a mixture of molecules of different types. Compare the rms speeds of the molecules of N_2, O_2, and CO_2 at standard conditions. What assumptions did you make?
21. * How many moles of air are in a regular 1-L water bottle when you finish drinking the water? What assumptions did you make? How do these assumptions affect your result?

22. * At approximately what temperature does the average translational kinetic energy of a N_2 molecule in an ideal gas equal the macroscopic translational kinetic energy of a copper atom in a penny that is dropped from the height of 1.0 m?
23. ** A molecule moving at speed v_1 collides head-on with a molecule of the same mass moving at speed v_2. Compute the speeds of the molecules after the collision. What assumptions did you make? How does the answer to this problem explain why the mixing of hot and cold gases causes the cold gas to become warmer and the hot gas to become cooler?
24. * **Balloon flight** For a balloon ride, the balloon must be inflated with helium to a volume of 1500 m^3 at sea level. The balloon will rise to an altitude of about 12 km, where the temperature is about −52 °C and the pressure is about 20 kPa. How many kg of helium should be put into the balloon? What assumptions did you make?
25. BIO **Ears pop** The middle ear has a volume of about 6.0 cm^3 when at a pressure of 1.0×10^5 N/m^2. Determine the volume of that same air when the air pressure is 0.83×10^5 N/m^2, as it is at an elevation of 1500 m above sea level (assume the air temperature remains constant). If the volume of the middle ear remains constant, some air will have to leave as the elevation increases. That is why ears "pop."
26. * Even the best vacuum pumps cannot lower the pressure in a container below 10^{-15} atm. How many molecules of air are left in each cubic centimeter in such a "vacuum"? Assume that the temperature is 273 K.
27. **Pressure in interstellar space** The concentration of particles (assume neutral hydrogen atoms) in interstellar gas is 1 particle/cm^3, and the average temperature is about 3 K. What is the pressure of the interstellar gas? How does it compare to the best vacuum that can be achieved on Earth (see the previous problem)?

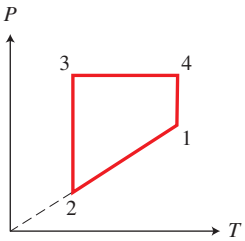
12.5, 12.6, and 12.7 Testing the ideal gas law, Speed distribution of particles, and Skills for analyzing processes using the ideal gas law

28. * Describe experiments to determine if each of the three gas isoprocess laws works. The experiments should be ones that you could actually carry out.
29. * The following data were collected for the temperature and volume of a gas. Can this gas be described by the ideal gas model? Explain how you know.

Temperature (°C)	Volume (mL)
11	95.0
25	100.0
47	107.5
73	116.0
159	145.1
233	170.0
258	177.9

30. * Explain the microscopic mechanisms for the relation of macroscopic variables for an isothermal process, an isobaric process, and an isochoric process occurring in an ideal gas.
31. ** **Scuba diving** The pressure of the air in a diver's lungs when he is 20 m under the water surface is 3.0×10^5 N/m^2, and the air occupies a volume of 4.8 L. How many moles of air should he exhale while moving to the surface, where the pressure is 1.0×10^5 N/m^2?
32. * When surrounded by air at a pressure of 1.0×10^5 N/m^2, a basketball has a radius of 0.12 m. Compare its volume at this condition with the volume that it would have if you took it 15 m below the water surface, where the pressure is 2.5×10^5 N/m^2. What assumptions did you make?
33. * Some students are given the following problem: "A 5000-cm^3 cylinder is filled with nitrogen gas at 1.0×10^5 Pa and 300 K and closed with a movable piston. The gas is slowly compressed at constant temperature to a final volume of 5 cm^3. Determine the final pressure of the gas." (a) Explain why the ideal gas law cannot be applied to solve this problem. Present quantitative arguments. (b) Modify the problem so that it *can* be solved using the ideal gas law and give your solution.
34. ** You have gas in a container with a movable piston. The walls of the container are thin enough so that its temperature stays the same as the temperature of the surrounding medium. You have baths of water of different temperatures, different objects that you can place on top of the piston, etc. (a) Describe how you could make the gas undergo an isothermal process so that the pressure inside increases by 10%, then undergo an isobaric process so that the new volume decreases by 20%, and finally undergo an isochoric process so that the temperature increases by 15%. (b) Represent this three-step process in *P*-versus-*T*, *V*-versus-*T*, and *P*-versus-*V* graphs. (c) Express the new pressure, volume, and temperature in terms of their initial values.
35. * You want to determine the temperature in a freezer using the following equipment: an empty plastic bottle with a cap, a graduated measuring cylinder, and a bowl of water. You also know your room temperature T_R. (a) Which of the procedures described below will give data from which you can determine the temperature in the freezer? (b) For the procedure that you have chosen in part (a), derive the expression for the temperature in the freezer as a function of relevant physical quantities. Indicate any assumptions that you made.
    I. Put the open plastic bottle into the freezer for half an hour. Take the bottle out, turn it upside down into the water, and measure the volume of the water sucked into the bottle.
    II. Put the open plastic bottle in the freezer for half an hour. Take the bottle out and close it tightly with a cap. Wait until the bottle's shape stops changing. Turn the bottle upside down into the water, open the cap, and measure the volume of the water that entered the bottle.
    III. Put the closed plastic bottle in the freezer for half an hour. Take the bottle out, turn it upside down into the water, and then open the cap. Measure the volume of the water sucked into the bottle.
    IV. Put the closed plastic bottle in the freezer for half an hour. Take the bottle out, open the cap, and turn the bottle upside down into the water. Measure the volume of the water sucked into the bottle.
36. * **Bubbles** While snorkeling, you see air bubbles leaving a crevice at the bottom of a reef. One of the bubbles has a radius of 0.060 m. As the bubble rises, the pressure inside it decreases by 50%. Now what is the bubble's radius? What assumptions did you make to solve the problem?
37. ** **Diving bell** A cylindrical diving bell, open at the bottom and closed at the top, is 4 m tall. Scientists fill the bell with air at the pressure of 1.0×10^5 N/m^2. The pressure increases naturally by 1.0×10^5 N/m^2 for each 10 m that the bell is lowered below the surface of the water. If the bell is lowered 30 m below the ocean surface, how many meters of air space are left inside the bell? Why doesn't water enter the entire bell as it goes under water? Draw several sketches for this problem. Assume the temperature remains constant.
38. * **Mount Everest** (a) Determine the number of molecules per unit volume in the atmosphere at the top of Mount Everest. The pressure is 0.31×10^5 N/m^2, and the temperature is −30 °C. (b) Determine the number of molecules per unit volume at sea level, where the pressure is 1.0×10^5 N/m^2 and the temperature is 20 °C.
39. * EST **Breathing on Mount Everest** Using the information from Problem 12.38, estimate how frequently you need to breathe on top of Mount Everest to inhale the same amount of oxygen as you do at sea level. The pressure is about one-third the pressure at sea level.
40. * **Capping beer** You would like to make homemade beer, but you are concerned about storing it. Your beer is capped into a bottle at a temperature of 27 °C and a pressure of 1.2×10^5 N/m^2. The cap will pop off if the pressure inside the bottle exceeds 1.5×10^5 N/m^2. At what maximum temperature can you store the beer so the gas inside the bottle does not pop the cap? List the assumptions that you made.
41. **Car tire** With a tire gauge, you measure the pressure in a car tire as 2.1×10^5 N/m^2. How can this be if you know that absolute pressure in the tire is three times higher than atmospheric? The tire looks okay. What's the deal?
42. * **Car tire dilemma** Imagine a car tire that contains 5.1 moles of air when at a gauge pressure of 2.1×10^5 N/m^2 (the pressure above atmospheric pressure) and a temperature of 27 °C. The temperature increases to 37 °C, the volume decreases to 0.8 times the original volume, and the gauge pressure decreases to 1.6×10^5 N/m^2. Can these measurements be correct if the tire did not leak? If it did leak, then how many moles of air are left in the tire?

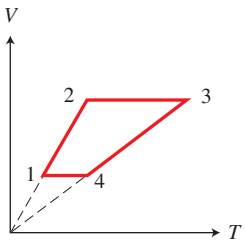
43. * There is a limit to how much gas can pass through a pipeline, because the pipes can only tolerate so much pressure on the walls. To increase the amount of gas going through the pipeline, engineers decide to cool the gas (to reduce its pressure). Suggest how much they should lower the temperature of the gas if they want to increase the mass per unit time by 1.5 times.
44. Explain how you know that the volume of one mole of gas at standard conditions is 22.4 L.
45. * At what pressure is the density of −50 °C nitrogen gas (N_2) equal to 0.01 times the density of water?
46. * In the morning, the gauge pressure in your car tires is 35 psi. During the day, the air temperature increases from 20 °C to 30 °C and the pressure increases to 36.5 psi. By how much did the volume of one of the tires increase? What assumptions did you make?
47. **Equation Jeopardy 1** The equation below describes a process. Construct a word problem for a process that is consistent with the equations (there are many possibilities). Provide as much detailed information as possible about your proposed process.



$$\frac{1.2 \times 10^5\ \text{N/m}^2}{293\ \text{K}} = \frac{2.0 \times 10^5\ \text{N/m}^2}{T}$$

48. * **Equation Jeopardy 2** The equation below describes a process. Construct a word problem for a process that is consistent with the equations (there are many possibilities). Provide as much detailed information as possible about your proposed process.

$$\Delta n = \frac{(0.67 \times 10^5\ \text{N/m}^2)(0.60 \times 10^{-6}\ \text{m}^3)}{(8.3\ \text{J/mole}\cdot\text{K})(303\ \text{K})} - \frac{(1.00 \times 10^5\ \text{N/m}^2)(0.60 \times 10^{-6}\ \text{m}^3)}{(8.3\ \text{J/mole}\cdot\text{K})(310\ \text{K})}$$



49. ** The P-versus-T graph in Figure P12.49 describes a cyclic process comprising four hypothetical parts. (a) What happens to the pressure of the gas in each part? (b) What happens to the temperature of the gas in each part? (c) What happens to the volume of the gas in each part? (d) Explain each part microscopically. (e) Use the information from (a)–(c) to represent the same parts in P-versus-V and V-versus-T graphs. (Hint: It helps to align the P-versus-V graph *beside* the P-versus-T graph using the same P values on the ordinate (vertical axis) and to place the V-versus-T graph *below* the P-versus-T graph using the same T values on the abscissa (horizontal axis). This helps keep the same scale for the variables.)

FIGURE P12.49

50. ** The V-versus-T graph in Figure P12.50 describes a cyclic process comprising four hypothetical parts. (a) What happens to the pressure of the gas in each part? (b) What happens to the temperature of the gas in each part? (c) What happens to the volume of the gas in each part? (d) Explain each part microscopically. (e) Use the information from (a)–(c) to represent the same process in a P-versus-T graph (below the V-versus-T graph) and a P-versus-V graph (beside the P-versus-T graph). See the hint in the previous problem about the graph alignments.

FIGURE P12.50

51. * BIO **Breathing** You are breathing heavily while hiking up the mountain. To inhale, you expand your diaphragm and lungs. Explain, using your knowledge of gas pressure, why this mechanical movement leads to the air flowing into your nose or mouth. Support your reasoning with diagrams if necessary.

12.8 Thermal energy, the Sun, and diffusion

52. * The temperature of the Sun's atmosphere near the surface is about 6000 K, and the concentration of atoms is about 10^{15} particles/m^3. What are the average pressure and density of its atmosphere? What assumptions did you make to solve the problem?
53. * BIO EST **Breathing and metabolism** We need about 0.7 L of oxygen per minute to maintain our resting metabolism and about 2 L when standing and walking. Estimate the number of breaths per minute for a person to satisfy this need when resting and when standing and walking. What assumptions did you make? Remember that oxygen is about 21% of the air.
54. * EST **Sun's life expectancy** (a) Estimate the average kinetic energy of the particles in the Sun. Assume that it is made of atomic hydrogen and that its average temperature is 100,000 K. The mass of the Sun is 2×10^{30} kg. (b) For how long would the Sun shine using this energy if it radiates 4×10^{26} W/s? Is your answer reasonable? Explain.
55. ** A gas that can be described by the ideal gas model is contained in a cylinder of volume V. The temperature of the gas is T. The mass of the gas is m, and the molar mass is M. Write an expression for the total thermal energy of the gas. Now, imagine that the exact same gas has been placed in a container of volume $2V$. What happens to its pressure? What happens to its temperature? What happens to its thermal energy?
56. * **Equation Jeopardy 3** The three equations below describe a physical situation. Construct a word problem for a situation that is consistent with the equations (there are many possibilities). Provide as much detailed information as possible about the situation.

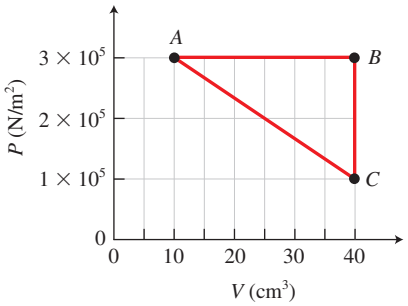
$$m = (1.3\ \text{kg/m}^3)(3.0\ \text{m} \times\ 5.0\ \text{m} \times\ 2.0\ \text{m})$$
$$N = m/[\,(29 \times 10^{-3}\ \text{kg})/(6.0 \times 10^{23}\ \text{particles})]$$
$$U_{\text{th}} = N(3/2)(1.38 \times 10^{-23}\ \text{J/K})(273\ \text{K})$$

General Problems

FIGURE P12.57

57. * EST A simple experimental setup for performing isobaric processes can be made with a thin glass tube filled with a gas and closed with a drop of water (Figure P12.57). If the pressure of the gas changes, the drop moves until the sum of the forces exerted on the drop is zero (there is no friction between the drop and the tube). The inner diameter of the glass tube is 3.0 mm and the length of the tube is 200.0 mm. At normal room temperature, a 5.0-mm-long water drop is 30.0 mm from the open end of the tube. Estimate the temperature range in which this setup can be used to show isobaric processes. (Hint: What happens to water at low temperature?)

VIDEO 12.1



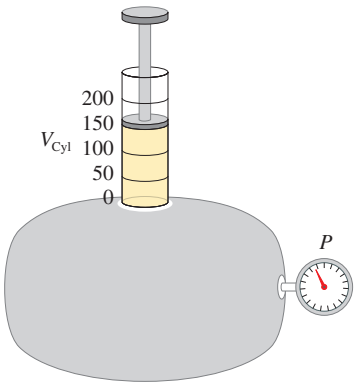
58. * See the previous problem. Explain how the force exerted by Earth on the water drop and the orientation of the tube affects the performance of the setup.
59. * Jeff and Natalie notice that a rubber balloon, which is first in a warm room, shrinks when they take it into the garden on a cold winter day. They propose two different explanations for the observed phenomenon: (a) the balloon is slowly leaking; (b) the balloon shrinks due to decreased temperature while the pressure in the balloon remains constant (isobaric compression). In order to test their proposed explanations, Jeff and Natalie perform three consecutive experiments: they measure the volume of the balloon and the temperature of the air near the balloon (1) in the room, (2) in the garden, and (3) again in the room. Their measurements, including uncertainties, are presented in the table below.

Exp. #	Location	Temperature	Volume of the balloon
1	Room	26.2 °C ± 0.1 °C	7500 cm^3 ± 400 cm^3
2	Garden	−15.3 °C ± 0.1 °C	6400 cm^3 ± 400 cm^3
3	Room	26.2 °C ± 0.1 °C	7300 cm^3 ± 400 cm^3

Based on the data, can Jeff and Natalie reject any of their hypotheses? Explain. Make sure you include uncertainties in your answer.

60. * **Different planet compositions** Explain why planets closer to the Sun have low concentrations of light elements, but light elements are relatively abundant in giant planets such as Jupiter, Uranus, and Saturn, which are far from the Sun.
61. ** EST **Density of our galaxy** Estimate the average density of particles in our galaxy, assuming that the most abundant element is atomic hydrogen. There are about 10^{11} stars in the galaxy and the size of the galaxy is about 10^5 light-years. A light-year is the distance light travels in 1 year moving at a speed of 3×10^8 m/s. What do you need to assume about the stars in order to answer this question?
62. * BIO **Breathing** During each breath you probably inhale about 0.50 L of air. How many oxygen molecules do you inhale if you are at sea level?
63. * **Car engine** During a compression stroke of a cylinder in a diesel engine, the air pressure in the cylinder increases from 1.0×10^5 N/m^2 to 50×10^5 N/m^2, and the temperature increases from 26 °C to 517 °C. A typical compression ratio (the ratio of the largest and the smallest volume of a cylinder) for a diesel engine is 20:1. Using this information, how would you convince your friends that knowledge about ideal gases can help explain how hot gases burned in the car engine affect the motion of the car?
64. * EST How can the pressure of air in your house stay constant during the day if the temperature rises? Estimate the volume of your house and the number of moles of air that leave the house during the daytime. Assume that nighttime temperature and daytime temperature differ by about 10 °C. List all other assumptions that are necessary to answer the question.
65. * **Tell-all problem** Tell everything you can about a process that was performed with 2×10^{-3} moles of a gas and that is described by the pressure-versus-volume graph shown in Figure P12.65.

FIGURE P12.65



66. ** Two massless, frictionless pistons are inside a horizontal tube opened at both ends. A 10-cm-long thread connects the pistons. The cross-sectional area of the tube is 20 cm^2. The pressure and temperature of gas between the pistons and the outside air are the same and are equal to $P = 1.0 \times 10^5$ N/m^2 and $T = 24$ °C. At what temperature of the gas will the thread break if it breaks when the tension reaches 30 N?
67. * A closed cylindrical container is divided into two parts by a light, movable, frictionless piston. The container's total length is 100 cm. Where is the piston located when one side is filled with nitrogen (N_2) and the other side with the same mass of hydrogen (H_2) at the same temperature?
68. How many molecules are there in 1 g of air at normal conditions? If these molecules were distributed uniformly on Earth's surface, *estimate* the number that would be under your feet right now. The radius of Earth is about 6400 km.
69. ** The speed of sound in an ideal gas is given by the relationship

$$v = \sqrt{\frac{\gamma RT}{M}}$$

where R = the universal gas constant = 8.314 J/mol · K; T = the absolute temperature; M = the molar mass of the gas in kg/mol; and γ is a characteristic of the specific gas. For air, $\gamma = 1.4$ and the average molar mass for dry air is 28.95 g/mol. (a) Show that the equation gives you correct units. (b) Give reasons why the temperature of the gas is in the numerator and the molar mass of the gas is in the denominator.
70. * Using the information from problem 12.69, calculate the speed of sound in the air. What assumptions are you making?
71. * **Speed of sound in summer and winter** Using the information in problem 12.69, estimate how much faster sound travels in summer than in winter. Explain how you arrived at your answer and the assumptions that you made.
72. ** A chamber of unknown volume is filled with an unknown amount of ideal gas. A cylinder with an open bottom and calibrated volume is connected to the chamber and is closed with a movable piston. A gas pressure sensor is also mounted on the chamber (Figure P12.72). The whole experimental setup is kept at a constant temperature of 300 K. Doris moves the piston from mark 0 to mark 200 mL in steps of 50 mL and records the corresponding pressure in the chamber. She moves the piston very slowly and waits several minutes before recording the pressure values. Use Doris's data in the table to determine the volume of the chamber and the number of moles of gas. (Note: This is a problem that requires linearization of data.)

V_{Cyl} (mL)	P (10^5 N/m^2)
0	4.35
50	3.85
100	3.50
150	3.15
200	2.90

FIGURE P12.72

Reading Passage Problems

BIO **Vascular wall tension and aortic blowout** The walls of blood vessels contain varying amounts of elastic fibers that allow the vessels to expand and contract as the pressure and amount of fluid inside vary (these fibers are more prevalent in the aorta and large arteries than in the small arterioles and capillaries). These fibers in the cylindrical walls produce a wall tension T, defined as

$$T = \frac{F}{L}$$

where L is the length of an imaginary cut parallel to the axis of the vessel and F is the magnitude of the force that each side of the cut must exert on the other side to hold the two sides together.

Three forces are exerted on a short section of wall fiber—the system. (1) The fluid inside pushes outward, due to fluid pressure from inside $P_{\text{inside fluid pushing out}} = P_{\text{out}}$; (2) fluid outside the vessel pushes inward, due to fluid pressure from outside $P_{\text{outside fluid pushing in}} = P_{\text{in}}$; and (3) the wall next to the system exerts wall tension T on each side of that wall. The pressure difference across the wall $\Delta P = P_{\text{out}} - P_{\text{in}}$, the wall tension T, and the radius R of the cylindrical vessel are related by Laplace's law:

$$\Delta P = \frac{T}{R} \quad \text{or} \quad T = \Delta P \cdot R$$

The inward gauge pressure P_{in} of tissue surrounding the vessels is approximately zero. Thus, the pressure difference $\Delta P = P_{\text{out}} - P_{\text{in}} = P_{\text{vessel}} - 0 = P_{\text{vessel}}$ is the gauge pressure in the blood vessel. We can now estimate the wall tension for different types of vessels. The tension in the aorta is approximately

$$T = \Delta P \cdot R \approx (100 \text{ mm Hg})\left(\frac{133 \text{ N/m}^2}{1 \text{ mm Hg}}\right)(1.3 \times 10^{-2} \text{ m}) = 170 \text{ N/m}$$

Using similar reasoning, the wall tension in the low-pressure, very small radius capillaries is about 0.016 N/m—about 0.0003 times the tension needed to tear a facial tissue. Because such little tension is needed to hold a capillary together, its wall can be very thin, allowing easy diffusion of various molecules across the wall.

The walls of a healthy aorta can easily provide the tension needed to support the increased blood pressure when it fills with blood from the heart during each heartbeat. However, aging and various medical conditions may weaken the aortic wall in a short section, and increased blood pressure can cause it to stretch. The weakened wall bulges outward; this is called an aortic aneurism. The increased radius causes increased tension, which can increase bulging. This cycle can result in a rupture to the aorta: an aortic blowout.

73. Why is the wall tension in capillaries so small?
    (a) There are so many capillaries.
    (b) Their radii are so small.
    (c) The outward pressure of the blood inside is so small.
    (d) b and c
    (e) a, b, and c
74. Which answer below is closest to the wall tension in a typical arteriole of radius 0.15 mm and 60 mm Hg blood pressure?
    (a) 0.001 N/m (b) 0.01 N/m
    (c) 0.1 N/m (d) 1 N/m
    (e) 10 N/m
75. According to Laplace's law, elevated blood pressure in an artery should cause the wall tension in the artery to do what?
    (a) Increase (b) Remain unchanged
    (c) Decrease (d) Impossible to decide
76. As a person ages, the fibers in arteries become less elastic and the wall tension increases. According to Laplace's law, this will cause the blood pressure to do what?
    (a) Increase (b) Remain unchanged
    (c) Decrease (d) Impossible to decide
77. Aortic blowout occurs when part of the wall of the aorta becomes weakened. What does this cause?
    (a) A bulge and increased radius of the aorta when the blood pressure inside increases
    (b) An increased radius of the aorta, which causes increased tension in the wall
    (c) An increased tension in the aorta, which causes the radius to increase
    (d) a and b
    (e) a, b, and c

BIO Portable hyperbaric chamber In 1997, a hiking expedition was stranded for 38 days on the Tibetan side of Mount Everest at altitudes between 5200 m and 8000 m. While at those altitudes, 10 climbers suffered acute mountain sickness. A 37-year-old climber with acute pulmonary edema (buildup of fluid in the lungs) was treated with a portable Gamow bag (see **Figure 12.20**), named after its inventor, Igor Gamow. The Gamow bag is a windowed cylindrical portable hyperbaric chamber constructed of nonpermeable nylon that requires constant pressurization with a foot pump attached to the bag. The climber enters the bag, and a person outside pumps air into the bag so that the air pressure inside is somewhat higher than the outside pressure.

FIGURE 12.20 A Gamow bag, used to help climbers with acute altitude sickness.

The bag and pump have a 6.76-kg mass. The volume of the inflated bag is 0.476 m^3. The maximal bag pressure is 0.15×10^5 N/m^2 above the air pressure at the site where it is used. In the 1997 climb, with the temperature at −20°C, the bag was filled in about 2 min with 10–20 pumps per minute. This raised the pressure in the bag to 0.58×10^5 N/m^2 (equivalent to an elevation of 4400 m) instead of the actual outside pressure of 0.43×10^5 N/m^2 at the 6450-m elevation at which the climber was treated. The treatment lasted for 2 h, with the climber inhaling about 15 times/min at about 0.5 L/inhalation, and was successful—the pulmonary edema disappeared.

78. What is closest to the volume of the Gamow bag?
    (a) 50 L (b) 100 L
    (c) 200 L (d) 500 L
    (e) 1000 L
79. What is closest to the temperature at the 6450-m elevation on the day described in the problem?
    (a) 37 K (b) 253 K
    (c) 20 K (d) −20 K
    (e) 273 K
80. What is closest to the number n of moles of air in the filled bag when at 4400 m?
    (a) 3 moles (b) 10 moles
    (c) 13 moles (d) 110 moles
    (e) 170 moles
81. What is closest to the number n of moles of air in the bag if its pressure is at the 6450-m level?
    (a) 3 moles (b) 10 moles
    (c) 13 moles (d) 110 moles
    (e) 170 moles
82. Estimate the fraction of the air in the Gamow bag that an occupant would inhale in 1 h, assuming no replacement of the air.
    (a) 0.01 (b) 0.1
    (c) 0.3 (d) 0.5
    (e) 1.0

Static Fluids

- **How can a hot air balloon fly for hours?**
- **Why is it dangerous for scuba divers to ascend from a deep-sea dive too quickly?**
- **Why, in water, does a 15-g nail sink but a cargo ship float?**

The first hot air balloon with a person on board was launched by the Montgolfier brothers in 1783. Hot air is less dense than cold air. By carefully balancing the density of the balloon and its contents with the density of air, the pilot can control the force that the outside cold air exerts on the balloon. What do pressure, volume, mass, and temperature have to do with this force?

BE SURE YOU KNOW HOW TO:

- Draw a force diagram for a system of interest (Section 3.1).
- Apply Newton's second law in component form (Section 4.2).
- Define pressure (Section 12.2).
- Apply the ideal gas law (Sections 12.3 and 12.4).

IN THE PREVIOUS CHAPTER, we constructed the ideal gas model and used it to explain the behavior of gases. The temperature of the gas and the pressure it exerted on surfaces played an important role in the phenomena we analyzed. We ignored the effect of the gravitational force exerted by Earth on the gas particles. This simplification was reasonable, since in most of the processes we analyzed the gases had little mass and occupied a relatively small region of space, like in a piston. In this chapter, our interest expands to include phenomena in which the force exerted by Earth plays an important role. We will confine the discussion to static fluids—fluids that are not moving.

13.1 Density

We are familiar with the concept of density (from Chapter 12). To find the density of an object or a substance, determine its mass m and volume V and then calculate the ratio of the mass and volume:

$$\rho = \frac{m}{V} \tag{13.1}$$

Archimedes (Greek, 287–212 B.C.) discovered how to determine the density of an object of irregular shape. First determine its mass using a scale. Then determine its volume by submerging it in a graduated cylinder with water (**Figure 13.1**). Finally, divide the mass in kilograms by the volume in cubic meters to find the density in kilograms per cubic meter. Using this method we find that the density of an iron nail is 7860 kg/m^3—relatively large. A gold coin has an even larger density—19,300 kg/m^3. The universe, though, contains much denser objects. For example, the rapidly spinning neutron star known as a pulsar (discussed in Chapter 9) has a density of approximately 10^{18} kg/m^3. **Table 13.1** lists the densities of various solids, liquids, and gases.

FIGURE 13.1 Measuring the density of an irregularly shaped object.

1. Measure mass of object.
2. Place the object in water in a graduated cylinder.
3. Measure the volume change of the water. Volume change of water = volume of object.
4. Density = $\rho = m/V$

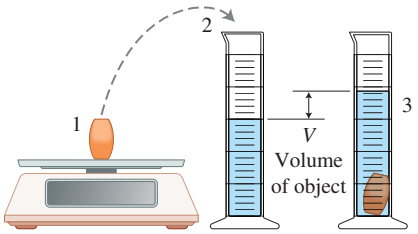

TABLE 13.1 Densities of various solids, liquids, and gases

Solids		Liquids[1]		Gases[2]	
Substance	Density (kg/m^3)	Substance	Density (kg/m^3)	Substance	Density (kg/m^3)
Aluminum	2700	Acetone	791	Dry air 0 °C	1.29
Copper	8920	Ethyl alcohol	789	10 °C	1.25
Gold	19,300	Methyl alcohol	791	20 °C	1.21
Iron	7860	Gasoline	726	30 °C	1.16
Lead	11,300	Olive oil	800–920	Helium	0.178
Platinum	21,450	Mercury	13,600	Hydrogen	0.090
Silver	10,500	Milk	1028–1035	Oxygen	1.43
Bone	1700–2000	Seawater	1025	Carbon dioxide	1.98
Brick	1400–2200	Water 0 °C	999.8		
Cement	2700–3000	3.98 °C	1000.00		
Clay	1800–2600	20 °C	998.2		
Glass	2400–2800	Blood plasma	1030		
Ice	917	Blood whole	1050		
Styrofoam	25–100				
Balsa wood	120				
Oak	600–900				
Pine	500				
Planet Earth	5515				
Moon	3340				
Sun	1410				
Universe (average)	10^{-26}				
Pulsar	10^{11}–10^{18}				

[1]Densities of liquids are at 0 °C unless otherwise noted.
[2]Densities of gases are at 0 °C and 1 atm unless otherwise noted.

QUANTITATIVE EXERCISE 13.1 **Ping-pong balls with different densities**

Saturn has the lowest density of all the planets in the solar system ($M_{\text{Saturn}} = 5.7 \times 10^{26}$ kg and $V_{\text{Saturn}} = 8.3 \times 10^{23}$ m^3). The average density of a neutron star is 10^{18} kg/m^3. Compare the mass of a ping-pong ball filled with material from Saturn with that of the same ball filled with material from a neutron star. An empty ping-pong ball has a 0.037-m diameter (0.020-m radius) and a 2.7-g mass.

Represent mathematically To find the mass of a ping-pong ball filled with a particular material, we add the mass of the ball alone and the calculated mass of the material inside:

$$m_{\text{filled ball}} = m_{\text{ball}} + m_{\text{material}}$$

where $m_{\text{material}} = \rho_{\text{material}} V_{\text{ball}}$.

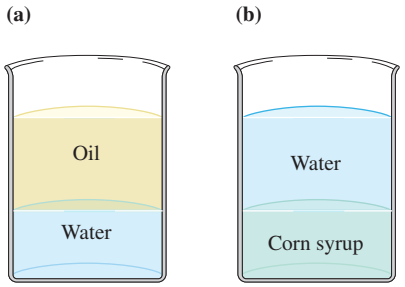
The density of the neutron star is given, and the density of Saturn can be found using the operational definition $\rho_{\text{Saturn}} = \dfrac{m_{\text{Saturn}}}{V_{\text{Saturn}}}$. The interior of the ping-pong ball is a sphere of volume $V_{\text{sphere}} = \frac{4}{3}\pi R^3$. Assume that the plastic shell of the ball has negligible volume. The mass of either filled ball is

$$\begin{aligned} m_{\text{filled ball}} &= m_{\text{ball}} + m_{\text{material}} = m_{\text{ball}} + \rho_{\text{material}} V_{\text{ball}} \\ &= m_{\text{ball}} + \rho_{\text{material}} \tfrac{4}{3}\pi R_{\text{ball}}^3 \end{aligned}$$

Solve and evaluate For the neutron-star-filled ball:

$$\begin{aligned} m_{\text{neutron star ball}} &= (0.003\text{ kg}) + (10^{18}\text{ kg/m}^3)\tfrac{4}{3}\pi(0.020\text{ m})^3 \\ &= 3.4 \times 10^{13}\text{ kg} \end{aligned}$$

For the Saturn-filled ball:



$$\begin{aligned} m_{\text{Saturn ball}} &= m_{\text{ball}} + \left(\frac{m_{\text{Saturn}}}{V_{\text{Saturn}}}\right)\left(\tfrac{4}{3}\pi R_{\text{ball}}^3\right) \\ &= 0.003\text{ kg} + \left(\frac{5.7 \times 10^{26}\text{ kg}}{8.3 \times 10^{23}\text{ m}^3}\right)\left(\tfrac{4}{3}\pi(0.020\text{ m})^3\right) \\ &= 0.003\text{ kg} + 0.023\text{ kg} = 0.026\text{ kg} \end{aligned}$$

The material from Saturn has less mass than an equal volume of water. The ball filled with the material from a neutron star has a mass of more than a billion tons!

Try it yourself The mass of the ping-pong ball filled with soil from Earth's surface is 0.050 kg. What is the density of the soil?

Answer 1400 kg/m^3.

FIGURE 13.2 Less dense matter floats on denser matter.

Density and floating

Understanding density allows us to pose questions about phenomena that we observe almost every day. For example, why does oil form a film on water? If you pour oil into water or water into oil, they form layers (see **Figure 13.2a**) independently of which fluid is poured first—the layer of oil is always on top of the water. The density of oil is less than the density of water. If you pour corn syrup and water into a container, the corn syrup forms a layer below the water (Figure 13.2b); the density of corn syrup is 1200 kg/m^3, greater than the density of water. Why, when mixed together, is the lower density substance always on top of the higher density substance?

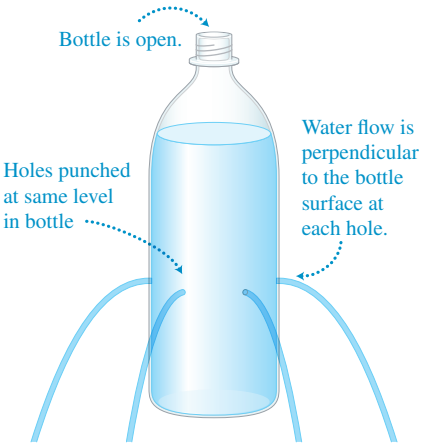
Similar phenomena occur with gases. Helium-filled balloons accelerate upward in air, while air-filled balloons accelerate (slowly) downward. The mass of helium atoms is much smaller than the mass of any other molecules in the air. (Recall that at the same pressure and temperature, atoms and molecules of gas have the same concentration; because helium atoms have much lower mass, their density is lower.) The air-filled balloon must be denser than air. The rubber with which the skin of any balloon is made is denser than air. We can disregard the slight compression of the gas by the balloon, because even though it increases the density of the gas, the effect is the same for both the air and helium in the balloons.

Ice (solid water) floats in liquid water

The solid form of a particular substance is almost always denser than the liquid form of the substance, with one very significant exception: liquid water and solid ice. Since ice floats on liquid water, we can assume that the density of ice is less than that of water. This is in fact true: the density of water changes slightly with temperature and is the highest at 4 °C: 1000 kg/m^3. The density of ice is 917 kg/m^3. Ice has a lower density because in forming the crystal structure of ice, water molecules spread apart. The fact that water expands when it forms ice is important for life on Earth (see the second Reading Passage at the end of this chapter). Fish and plants living in lakes survive cold winters in liquid

water under a shield of ice and snow at the surface. Water absorbed in the cracks of rocks freezes and expands in the winter, cracking the rock. Over the years, this process of liquid water absorption, freezing, and cracking eventually converts the rock into soil.

Why do denser forms of matter sink in less dense forms of matter? We learned (in Chapter 12) that the quantity *pressure* describes the forces that fluids exert on each other and on the solid objects they contact. Let us investigate whether pressure explains, for example, why a nail sinks in water or why a hot air balloon rises.



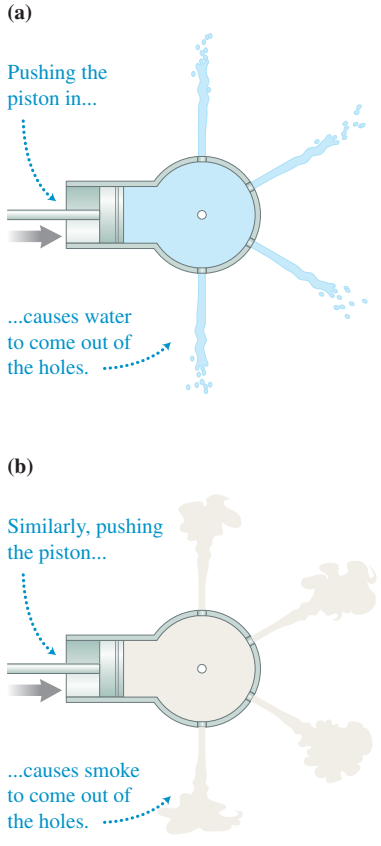
REVIEW QUESTION 13.1 How would you determine the density of an irregularly shaped object?

13.2 Pressure inside a fluid

We know that as gas particles collide with the walls of the container in which they reside, they exert pressure. In fact, if you place any object inside a gas, the gas particles exert the same pressure on the object as the gas exerts on the walls of the container. Do liquids behave in a similar way? In the last chapter we learned that the particles in a liquid are in continual random motion, somewhat similar to particles in gases.

Let's conduct a simple observational experiment. Take a plastic water bottle and poke several small holes at the same height along its perimeter. Close the holes with tacks, fill the bottle with water, open the cap, remove the tacks, and observe what happens (**Figure 13.3**). Identically shaped parabolic streams of water shoot out of the holes. The behavior of the water when the tacks are removed is analogous to a person leaning on a door that is suddenly opened from the other side—the person falls through the door. Evidently, the water inside must push out perpendicular to the wall of the bottle, just as gas pushes out perpendicular to the wall of a balloon. Due to their similar behaviors, liquids and gases are often studied together and are collectively referred to as **fluids**. In addition, since the four streams are identically shaped, the pressure at all points at the same depth in the fluid is the same.

FIGURE 13.3 Arcs of water leaving holes at the same level in a bottle.



Pascal's first law

Many practical applications involve situations in which an external object (for example, a piston) exerts a force on a particular part of a fluid. What happens to the pressure at other places inside the fluid? To investigate how the pressures at different points in a fluid are related, we use a special instrument that consists of a round glass bulb with holes in it connected to a glass tube with a piston on the other side (**Figure 13.4a**). When we fill the apparatus with water and push the piston, water comes out of all of the holes, not only those that align with the piston. When we fill the apparatus with smoke and push the piston, we get the same result (Figure 13.4b). The liquid and the gas behave similarly.

How can we explain this observation? Pushing the piston in one direction caused a greater pressure in the fluid close to the piston. It seems that almost immediately the pressure throughout the fluid increased as well, as the fluid was pushed out of *all* of the holes in the bulb in the same way. This phenomenon was first discovered by French scientist Blaise Pascal in 1653 and is called Pascal's first law.

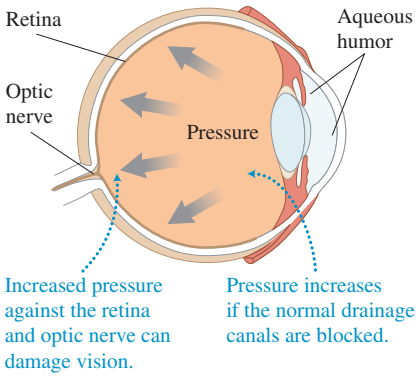


FIGURE 13.4 Pascal's first law: increasing the pressure of a fluid at one location causes a uniform pressure increase throughout the fluid.

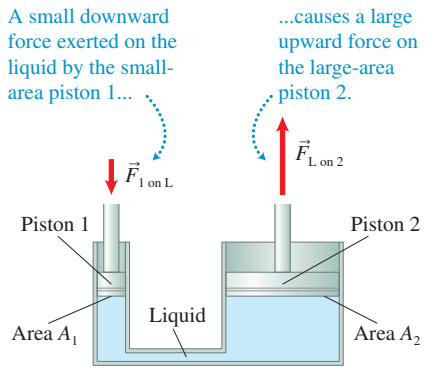
Pascal's first law An increase in the pressure of a static, enclosed fluid at one place in the fluid causes a uniform increase in pressure throughout the fluid.

The above experiment describes Pascal's first law macroscopically. We can also explain Pascal's first law at a microscopic level using gases as an example. Gas particles inside a container move randomly in all directions. When we push harder on one of the surfaces of the container, the gas compresses near that surface. The molecules near

FIGURE 13.5 Glaucoma is an increase in intraocular pressure, caused by blockage of the ducts that normally drain aqueous humor from the eye.

that surface collide more frequently with their neighbors farther from the surface. They in turn collide more frequently with their neighbors. The extra pressure exerted at the one surface quickly spreads, and soon there is increased pressure throughout the gas.



Glaucoma

Pascal's first law can help us understand a common eye problem—*glaucoma*. A clear fluid called *aqueous humor* fills two chambers in the front of the eye (**Figure 13.5**). In a healthy eye, new fluid is continually secreted into these chambers while old fluid drains from the chambers through sinus canals. A person with glaucoma has closed drainage canals. The buildup of fluid causes increased pressure throughout the eye, including at the retina and optic nerve, which can lead to blindness. Ophthalmologists diagnose glaucoma by measuring the pressure at the front of the eye. The eye pressure of a person with healthy eyes is about $1.2 \times 10^5\ \mathrm{N/m^2}$; a person with glaucoma has an elevated pressure of $1.3 \times 10^5\ \mathrm{N/m^2}$.

Hydraulic lift

One of the technical applications of Pascal's first law is a *hydraulic lift*, a form of simple machine that converts small forces into larger forces, or vice versa. Automobile mechanics use hydraulic lifts to lift cars, and dentists and barbers use them to raise and lower their clients' chairs. The hydraulic brakes of an automobile are also a form of hydraulic lift. Most of these devices work on the simple principle illustrated in **Figure 13.6**, although the actual devices are usually more complicated in construction.

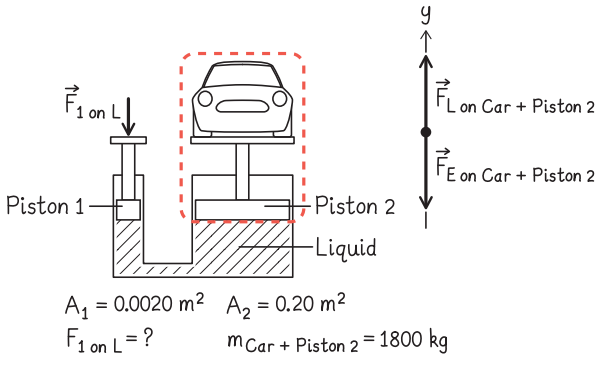
FIGURE 13.6 Schematic of a hydraulic lift.

In Figure 13.6, a downward force $\vec{F}_{1\text{ on L}}$ is exerted by piston 1 (with small area A_1) on the liquid. This piston compresses a liquid (usually oil) in the lift. The pressure in the liquid just under piston 1 is

$$P_1 = \frac{F_{1\text{ on L}}}{A_1}$$

Because the pressure changes uniformly throughout the liquid, the pressure under piston 2 is also $P = F_{1\text{ on L}}/A_1$, with a key assumption that the pistons are at the same elevation. Since piston 2 has a greater area A_2 than piston 1, the liquid exerts a greater upward force on piston 2 than the downward force on piston 1:

$$F_{\text{L on 2}} = PA_2 = \left(\frac{F_{1\text{ on L}}}{A_1}\right)A_2 = \left(\frac{A_2}{A_1}\right)F_{1\text{ on L}} \tag{13.2}$$



Since A_2 is greater than A_1, the lift provides a significantly greater upward force $F_{\text{L on 2}}$ on piston 2 than the downward push of the smaller piston 1 on the liquid $F_{1\text{ on L}}$.

EXAMPLE 13.2 **Lifting a car with one hand**

A hydraulic lift similar to that described above has a small piston with surface area $0.0020\ \mathrm{m^2}$ and a larger piston with surface area $0.20\ \mathrm{m^2}$. Piston 2 and the car placed on piston 2 have a combined mass of 1800 kg. What is the minimal force that piston 1 needs to exert on the fluid to slowly lift the car?

Sketch and translate The situation is similar to that shown in Figure 13.6. We need to find $F_{1\text{ on L}}$ so the fluid exerts a force great enough to support the mass of the car and piston 2. The hydraulic lift Eq. (13.2) should then allow us to determine $F_{1\text{ on L}}$.

Simplify and diagram Assume that the levels of the two pistons are the same and that the car is being lifted at constant velocity. Use the force diagram for the car and piston 2 (see diagram at right) and Newton's second law to determine $F_{\text{L on 2}}$. Note that the force that the liquid exerts on the large piston 2 $F_{\text{L on 2}}$ is equal in magnitude to the force that piston 2 and the car exert on the liquid $F_{2\text{ on L}}$, which equals the downward gravitational force that Earth exerts on the car and piston: $F_{2\text{ on L}} = m_{\text{Car+Piston}}g$.

Represent mathematically We rewrite the hydraulic lift Eq. (13.2) to determine the unknown force:

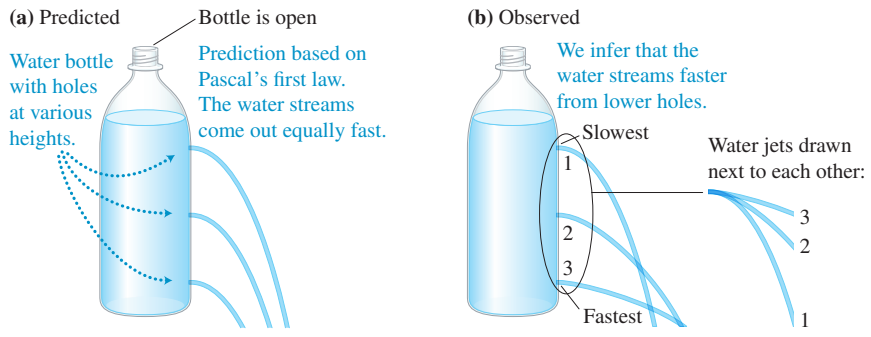
$$F_{1\text{ on L}} = \left(\frac{A_1}{A_2}\right)F_{2\text{ on L}} = \left(\frac{A_1}{A_2}\right)m_{\text{Car+Piston}}g$$

Solve and evaluate

$$F_{1\text{ on L}} = \frac{(0.0020\text{ m}^2)}{(0.20\text{ m}^2)}[(1800\text{ kg})(9.8\text{N/kg})] = 180\text{ N}$$

That is the force equal to lifting an object of mass 18 kg, which is entirely possible for a person. The units are also consistent.

Try it yourself If you needed to lift the car about 0.10 m above the ground, what distance would you have to push down on the small piston, assuming the model of the hydraulic lift applies to industrial lifts? Is the answer realistic, and what does it tell you about the operation of real hydraulic lifts?

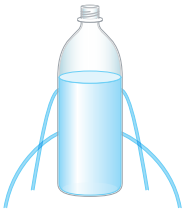


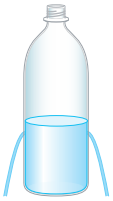
Answer 10 m. This answer is too large to be realistic. There must be some other technical details involved in the operation of industrial hydraulic lifts.

REVIEW QUESTION 13.2 If you poke many small holes in a closed toothpaste tube and squeeze it, the paste comes out equally from all holes. Why?

13.3 Pressure variation with depth

Pascal's first law states that an increase in the pressure in one part of an enclosed fluid results in an increase at all other parts of the fluid. Does that mean that the pressure is the same throughout a fluid—for example, in a vertical column of fluid? To test this hypothesis, consider another experiment with a water bottle. This time, poke vertical holes along one side of the bottle. Place tacks in the holes, and fill the bottle with water. Leave the cap off. If the pressure is the same throughout the fluid, when the tacks are removed the water should come out of each hole making an arc of the same shape, similar to projectiles thrown horizontally at the same speed, as shown in **Figure 13.7a**.





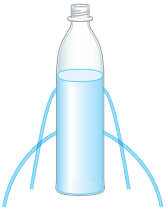


FIGURE 13.7 Water seems to be pushed harder from holes deeper in the water.

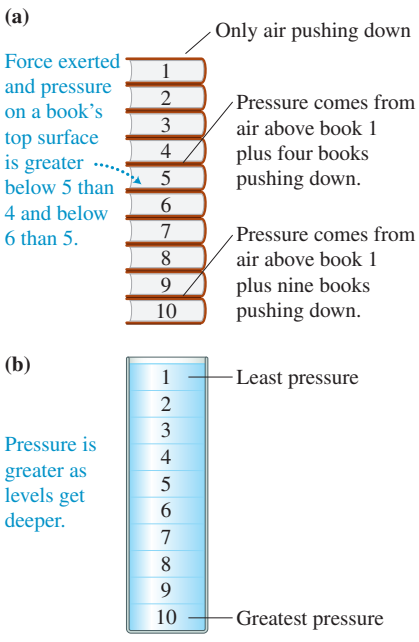
However, when the tacks are removed, we observe that the shapes of the arcs are different. The arcs produced by the water coming out from the lower holes resemble the trajectories of projectiles thrown at higher speeds (Figure 13.7b). Should we abandon Pascal's first law now because the prediction based on it did not match the outcome of the experiment? In such cases, scientists do not immediately throw out the principle but first examine the additional assumptions that were used to make the prediction. In our first experiment with the water bottle, we did not consider the impact of poking holes at different heights. Maybe this was an important factor in the experiment. Let's investigate this in Observational Experiment **Table 13.2**, on the next page.

OBSERVATIONAL EXPERIMENT TABLE 13.2 How does the location of the holes affect the streams leaving the holes?



VIDEO OET 13.2

Observational experiment		Analysis
Experiment 1. Place two tacks on each side of a plastic bottle, one hole above the other, and fill the bottle with water above the top tack. Remove the tacks. Water comes out on the left and right, and the stream from the lower holes resembles a projectile thrown at a higher speed.		There must be greater pressure inside than outside. The pressure must be greater at the bottom holes than at the top holes.
Experiment 2. Repeat Experiment 1 but this time fill the bottle with water to the same distance above the bottom tack as it was filled above the top tack in Experiment 1. Remove the tacks. The stream comes out the bottom holes with the same arc as it came out of the top holes in Experiment 1.		The total water depth seems not to matter, just the height of the water above the hole.
Experiment 3. Repeat Experiment 1 using a thinner bottle with the water level initially the same distance above the top tack as it was in Experiment 1. Remove the tacks. The water streams are identical to those in Experiment 1.		Because the water comes out in exactly the same arc in a bigger bottle and in a smaller bottle when the water level above the top tack is at the same height, we can conclude that the mass of the water in the bottle does not affect the pressure.

Patterns

The stream shape at a particular level:
- Depends on the depth of the water above the hole.
- Is the same in different directions at the same level.
- Does not depend on the amount of water (volume or mass) above the hole.
- Does not depend on the amount (mass or volume) or depth of the water below the hole.

FIGURE 13.8 Pressure increases with depth.

From the patterns above we reason that the pressure of the fluid at the hole depends only on the *depth* of the fluid above the hole, and not on the *mass* of the fluid above. We also see that the pressure at a given depth is the same in all directions. This is consistent with the experience you have when you dive below the surface of the water in a swimming pool, lake, or ocean. The pressure on your ears depends only on how deep you are below the surface. Pascal's first law fails to explain this pressure variation at different depths below the surface. Now we need to understand why the pressure varies with depth and to devise a rule to describe this variation quantitatively.

Why does pressure vary at different levels?

To explain the variation of pressure with depth we can use an analogy of stacking ten books on a table (**Figure 13.8a**). Imagine that each book is a layer of water in a cylindrical tube (see Figure 13.8b). Consider the pressure (force per unit area) from above on the top surface of each book. The only force exerted on the top surface of the top book is due to air pushing down from above. However, there are in effect two forces exerted on the top surface of the second book: the force that the top book exerts on it (equal in magnitude to the weight of the book) plus the force exerted by the air on the top book. The top surface of the bottom book in the stack must balance the force exerted by the nine books above it (equal in magnitude to the weight of nine books) plus

the pressure force exerted by the air on the top book. So the pressure increases on the top surface of each book in the stack as we go lower in the stack.

Similar reasoning applies for the fluid-filled tube divided into a number of imaginary thin layers in Figure 13.8b. Air pushes down on the top layer. The second layer balances the weight of the top layer plus the force exerted by the air pushing down on the top layer, and so on. The pressure is lowest at the top of the fluid and greatest at the bottom.

Note that, at each layer, the pressure in a fluid is the same in all directions. If we could take a pressure sensor and place it inside the container of water, the readings of the sensor would be the same independent of the orientation of the sensor as long as its depth remains the same.

How can we quantify pressure change with depth?

We know that pressure increases with depth, and according to our model of pressure using layers, we can hypothesize that it increases with depth linearly (assuming that the density of the fluid remains constant). But what is the slope of the pressure-versus-depth graph, and what is the intercept? Consider the shaded cylinder C of water shown in **Figure 13.9a** as our system of interest. The walls on opposite sides of the cylinder push inward, exerting equal-magnitude and oppositely directed forces—the forces exerted by the sides cancel. What about the forces exerted by the water above and below? If the pressure at elevation y_2 is P_2 and the cross-sectional area of the cylinder is A, then the fluid above pushes down, exerting a force of magnitude $F_{\text{fluid above on C}} = P_2A$ (Figure 13.9b). Similarly, fluid from below the shaded section of fluid at elevation y_1 exerts on the cylinder an upward force of magnitude $F_{\text{fluid below on C}} = P_1A$. Earth exerts a third force on the shaded cylinder $\vec{F}_{\text{E on C}}$ equal in magnitude to m_Cg, where m_C is the mass of the fluid in the cylinder. Since the fluid is not accelerating, these three forces add to zero. Choosing the y-axis pointing up, we have

$$\Sigma F_y = (-F_{\text{fluid above on C}}) + F_{\text{fluid below on C}} + (-m_Cg) = 0$$

Substituting the earlier expressions for the forces, we have

$$(-P_2A) + P_1A + (-m_Cg) = 0$$

The mass of the fluid in the shaded cylinder is the product of the fluid's density and the volume of the cylinder (assuming the density of the fluid is the same throughout the cylinder):

$$m_C = \rho_{\text{fluid}}V = \rho_{\text{fluid}}[A(y_2 - y_1)]$$

Substituting this expression for the mass in the above expression for the forces, we get

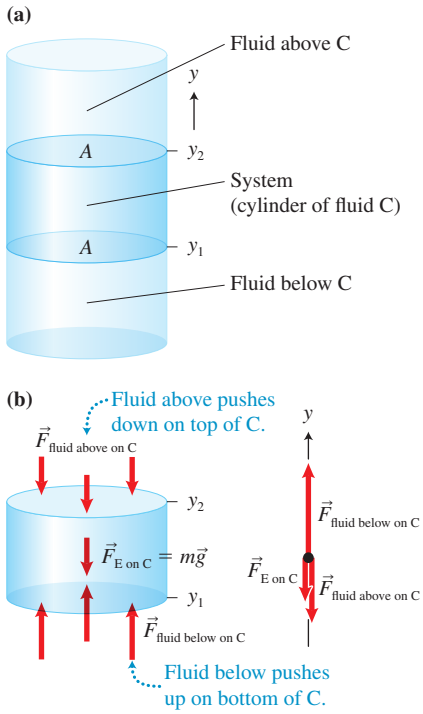
$$-P_2A + P_1A - \rho_{\text{fluid}}[A(y_2 - y_1)]g = 0$$

Divide by the common A in all of the terms and rearrange to get

$$P_1 = P_2 + \rho_{\text{fluid}}(y_2 - y_1)g \qquad (13.3)$$

This is Pascal's second law. As we see, pressure varies linearly with depth.

Pascal's second law—variation of pressure with depth The pressure P_1 in a static fluid at position y_1 can be determined in terms of the pressure P_2 at position y_2 as follows:



$$P_1 = P_2 + \rho_{\text{fluid}}(y_2 - y_1)g \qquad (13.3)$$

where ρ_{fluid} is the fluid density, assumed constant throughout the fluid, and $g = 9.8\ \text{N/kg}$. The positive y-direction is up. If y_2 is chosen to be the top of the fluid, then Eq. (13.3) can be simplified as

$$P_1 = P_{\text{atm}} + \rho_{\text{fluid}}gd \qquad (13.4)$$

where P_{atm} is the atmospheric pressure and d is the depth from the top of the fluid to the level at which we want to determine the pressure.

FIGURE 13.9 Using Newton's second law to determine how fluid pressure changes with the depth in the fluid.

TIP When using Pascal's second law [Eq. (13.3)], picture the situation and be sure to include a vertical y-axis that points upward and has a defined origin, or zero point. Then choose the two points of interest and identify their vertical y-positions relative to the axis. This lets you relate the pressures at those two points.

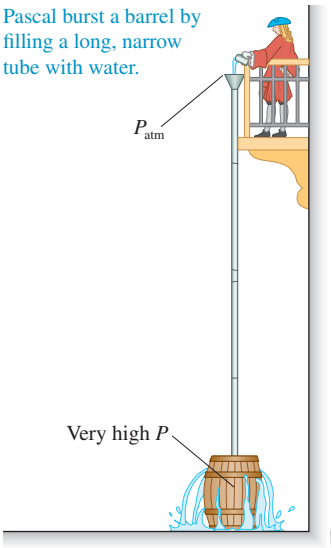


FIGURE 13.10 Pascal tests his second law.

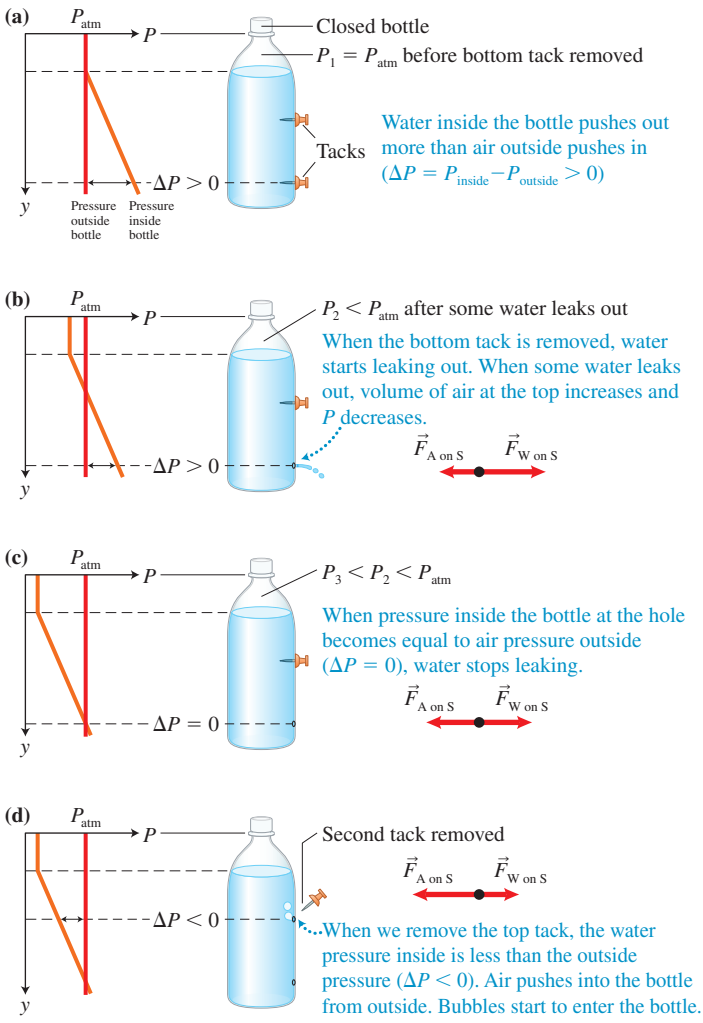
Some history of physics books say that Blaise Pascal conducted the following testing experiment for his second law. Pascal filled a barrel with water and inserted a long, narrow vertical tube into the water from above. He then sealed the barrel (see **Figure 13.10**). He predicted that when he filled the tube with water, the barrel would burst even though the mass of water in the thin tube was small, because the pressure of the water in the barrel would depend on the depth, not the mass, of the water column. The barrel burst, matching Pascal's prediction, thus supporting the idea that the depth of the fluid above, not its mass determined the pressure.



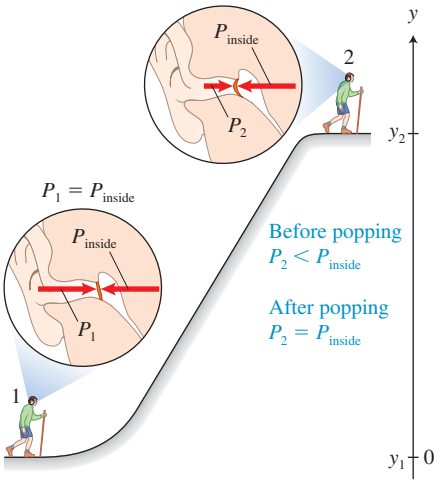
We derived Eqs. (13.3) and (13.4) using liquid as an example. The density of liquids does not change with depth because they are incompressible. Gases are compressible, and thus their density changes with depth. However, in all our examples, the changes in depth will be small enough so that we can neglect the density change in gases. Applying Eq. (13.3) to atmospheric air, we can explain why the pressure at the top of a mountain is less than at the bottom.

CONCEPTUAL EXERCISE 13.3 Closed water bottle with tacks

You have a closed plastic water bottle with two holes in the side closed with tacks, one tack near the bottom of the bottle and the other in the middle. You remove the bottom tack, and a few drops of water come out of the hole but then the leaking stops. Then you remove the top tack (with the bottom hole still open), and an air bubble enters the bottle through the top hole. Draw depth-versus-pressure graphs and force diagrams to explain this phenomenon.

Sketch and translate We sketch the bottle with two tacks in the holes. Let's choose the cap of the bottle to be the origin of the y-axis that points down; the horizontal axis will represent the pressure (Figure a).

Simplify and diagram We consider the pressure above the water level to be atmospheric at the beginning of the experiment (Figure a). Because only a few drops of water leave the bottle, we will neglect the changes in water level on the sketches and graphs. Figures b–d show the removal of the tacks and the changes in pressure on the graphs. We draw force diagrams for a tiny portion of water at the hole as our system of interest. There are two horizontal forces exerted on that system element of water: the force exerted by the outside air pushing inward $\vec{F}_{\text{A on S}}$ and the force of the inside water pushing outward $\vec{F}_{\text{W on S}}$. If one of the forces is smaller, then the tiny system of water will either accelerate outward and we will see the bottle leaking, or it will accelerate inward and we will see bubbles of air coming in. When a little bit of water leaks out, the volume of air above the water in the bottle increases, and its pressure decreases. This decrease leads to a decrease of the pressure everywhere inside the bottle.



Try it yourself Predict what will happen after an air bubble enters the bottle through the top hole.

Answer As new air enters the bottle, the air pressure above the water surface increases and so does the pressure elsewhere in the bottle. This results in more water leaking through the lower hole, which again decreases the pressure and causes more bubbles to enter the bottle, and so on. The process repeats until the water level drops to the upper hole. From then on, the water leaks out continuously until it reaches the level of the bottom hole.

QUANTITATIVE EXERCISE 13.4 **Pop your ears**

If your ears did not pop, then what would be the net force exerted by the inside and outside air on your eardrum at the top of a 1000-m-high mountain? You start your hike from sea level. The area of your eardrum is 0.50 cm^2. The density of air at sea level at standard conditions is 1.3 kg/m^3. Assume the air density remains constant during the hike. The situation at the start at $y_1 = 0$ and at the end of the hike at $y_2 = 1000$ m is sketched below.

Represent mathematically We use an upward-pointing vertical y-axis with the origin at sea level. Assume that the air pressure inside the eardrum remains constant at its sea level value $P_{inside} = P_1$. The air pressure difference between the top of the mountain and sea level is

$$P_2 - P_1 = \rho(y_1 - y_2)g$$

When at 1000 m above sea level, the outside air exerts a lower pressure P_2 on the eardrum. So the net force exerted by the air on the drum is the pressure difference of air pushing out $P_{inside} = P_1$ and air pushing in P_2 times the area of the eardrum: $F_{net\ air\ on\ drum} = (P_1 - P_2)A$. This pressure difference can be determined using Pascal's second law.

Solve and evaluate

$$\begin{aligned} P_1 - P_2 &= \rho(y_2 - y_1)g \\ &= (1.3\ kg/m^3)(1000\ m - 0)(9.8\ N/kg) \\ &= +0.13 \times 10^5\ N/m^2 \end{aligned}$$

This is 0.13 atm!

$$\begin{aligned} F_{net\ air\ on\ drum} &= (P_1 - P_2)A \\ &= (0.13 \times 10^5\ N/m^2)(0.50\ cm^2) \times (1\ m/100\ cm)^2 \\ &= +0.60\ N \end{aligned}$$

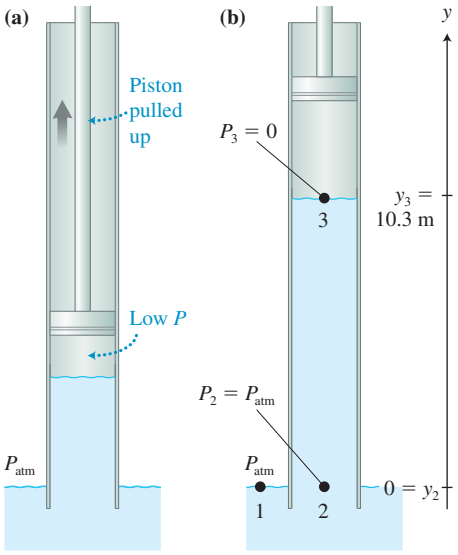
The net force is exerted outward and is about half the gravitational force that Earth exerts on an apple. No wonder it can hurt until you get some air out of that middle ear!

Try it yourself Determine the difference in water pressure on your ear when you are 1.0 m underwater compared to when you are at the surface. The density of water is 1000 kg/m^3.

Answer +9800 N/m^2, greater pressure when under the water, or 0.1 atm.

REVIEW QUESTION 13.3 Pascal's first law says that an increase in pressure in one part of an enclosed liquid results in an increase in pressure throughout all parts of that fluid. Why then does the pressure differ at different heights?

13.4 Measuring atmospheric pressure



We can now use Pascal's second law to develop a method for measuring atmospheric air pressure.

Torricelli's experiments

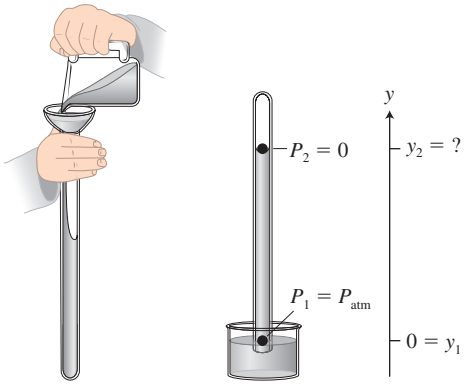
In the 1600s, suction pumps were used to lift drinking water from wells and to remove water from flooded mines. The suction pump was like a long syringe. The pump consisted of a piston in a long cylinder that pulled up water (**Figure 13.11a**). Such pumps could lift water a maximum of 10.3 m. Why 10.3 m?

Evangelista Torricelli (1608–1647), one of Galileo's students, hypothesized that the pressure of the air in the atmosphere could explain the limit to how far water could be lifted. Torricelli did not know of Pascal's second law, which was published in the year that Torricelli died. However, it is possible that Torricelli's work influenced Pascal. Let's analyze the situation shown in Figure 13.11b.

FIGURE 13.11 A piston pulled up a cylinder causes water to rise to a maximum height of 10.3 m.

Atmospheric pressure P_{atm} pushes water up the cylinder.

Consider the pressure at three places: point 1, at the water surface in the pool outside the cylinder; point 2, at the same elevation but inside the cylinder; and point 3, in the cylinder 10.3 m above the pool water level. The pressure at point 1 is atmospheric pressure. The pressure at point 2, according to Pascal's second law, is also atmospheric pressure, since it is at the same level as point 1. To get the water to the 10.3-m maximum height, the region above the water surface inside the cylinder and under the piston must be at the least possible pressure—essentially a vacuum. Thus, we assume that the pressure at point 3 is zero.



Now we will use Eq. (13.3) with $y_3 - y_2 = 10.3$ m to predict the pressure P_2:

$$P_2 = P_3 + \rho_{\text{water}}(y_3 - y_2)g = 0 + (1.0 \times 10^3\,\text{kg/m}^3)(10.3\text{ m} - 0)(9.8\text{ N/kg})$$
$$= 1.01 \times 10^5\,\text{N/m}^2$$

This number is exactly the value of the atmospheric pressure that we encountered in our discussion of gases (in Chapter 12). The atmospheric pressure pushing down on the water outside the tube can push water up the tube a maximum of 10.3 m if there is a vacuum (absence of any matter) above the water in the tube.

At Torricelli's time, the value of normal atmospheric pressure was unknown, so the huge number that came out of this analysis surprised Torricelli. Not believing the result, he tested it using a different liquid—mercury. Mercury is 14 times denser than water ($\rho_{\text{Hg}} = 13{,}600\,\text{kg/m}^3$); hence, the column of mercury should rise only 1/14 times as high in an evacuated tube. However, instead of using a piston to lift mercury, Torricelli devised a method that guaranteed that the pressure at the top of the column was about zero. Consider Testing Experiment **Table 13.3**.

TESTING EXPERIMENT TABLE 13.3  **Testing Torricelli's hypothesis using mercury**

Testing experiment	Prediction	Outcome
• Torricelli filled a long glass tube closed at one end with mercury. • He put his finger over the open end and placed it upside down in a dish filled with mercury. He then removed his finger.  Predict what he observed based on the hypothesis that atmospheric pressure limits the height of the liquid in a suction pump.	Mercury should start leaking from the tube into the dish. When it leaks, it leaves an empty evacuated space at the top of the tube. It will leak until the height of the mercury column left in the tube produces the same pressure as the atmosphere at the bottom of the column at position 1. The height of the mercury in the tube should be $y_2 - y_1 = \dfrac{P_1 - P_2}{\rho_{\text{mercury}} g}$ $= \dfrac{(1.01 \times 10^5\,\text{N/m}^2 - 0)}{(13.6 \times 10^3\,\text{kg/m}^3)\,(9.8\,\text{N/kg})}$ $= 0.76\text{ m}$	Torricelli observed some mercury leaking from the tube and then the process stopped. He measured the height of the remaining mercury to be 0.76 m = 760 mm, in agreement with the prediction.

Conclusion

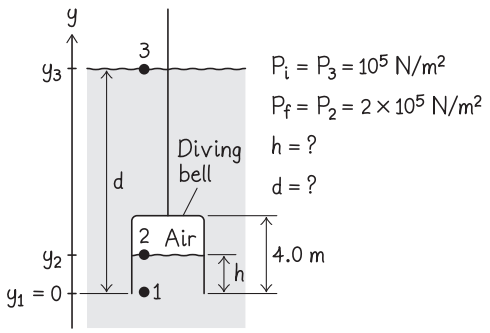
The outcome of the experiment was consistent with the prediction based on Torricelli's hypothesis that atmospheric pressure limits the height of the liquid being lifted in a suction pump. Thus the hypothesis is supported by evidence.

Torricelli also used his understanding of pressure and fluids to predict that in the mountains, where the atmospheric pressure is lower, the height of the mercury column should be lower. Experiments have shown that the mercury level indeed decreases at higher elevation. These experiments supported the explanation that atmospheric air pushes the liquids upward into the tubes.

Torricelli's apparatus with the mercury tube became a useful device for measuring atmospheric pressure—called a barometer. However, since mercury is toxic, the Torricelli device has since been replaced by the aneroid barometer (described in Chapter 12).

TIP We now understand why pressure is often measured and reported in mm Hg and why atmospheric pressure is 760 mm Hg. The atmospheric pressure ($101{,}000\ \text{N/m}^2$) can push mercury (density $13{,}600\ \text{kg/m}^3$) 760 mm up a column.

Eugenia, one of the book's authors, stands under a 17th-century diving bell displayed in the Vasa Museum in Stockholm, Sweden.



Diving bell

Our understanding of atmospheric pressure allows us to explain many simple experiments that lead to important practical applications. For example, have you ever submerged a transparent container upside down under water? If you have, you have seen that at first little water enters the container; then as the inverted container is pushed deeper into the water, more water enters the container. One practical application of this phenomenon is a diving bell—a large, bottomless chamber lowered under water with people and equipment inside. Divers use the diving bell to take a break and refill on oxygen. In the past, diving bells were used for underwater construction, such as building bridge foundations.

EXAMPLE 13.5 **Diving bell**

The bottom of a 4.0-m-tall cylindrical diving bell is at an unknown depth underwater. The pressure of the air inside the bell is $2.0 \times 10^5\ \text{N/m}^2$ (having been about $1.0 \times 10^5\ \text{N/m}^2$ before the bell entered the water). The density of ocean water is slightly higher than fresh water: $\rho_{\text{ocean water}} = 1027\ \text{kg/m}^3$. How high is the water inside the bell, and how deep is the bottom of the bell under the water?

Sketch and translate A labeled sketch shows the situation. We want to find the height h of the water in the bell and the depth d that the bottom of the bell is under the water.

Simplify and diagram Assume that the temperature is constant so we can apply our knowledge of an isothermal process (PV is constant for a constant temperature gas) to the air inside the bell and use it to relate the state of the air inside the bell before it is submerged to its state after it is submerged. This will let us find the ratio of the air volumes before and after, and from that we can determine h. Once we have that result, we can use Pascal's second law to determine d.

Represent mathematically Apply the mathematical expression for an isothermal process to the process of submerging the bell, where the initial state is just before the bell starts to be submerged in the water and the final state is when submerged to some unknown depth. We have

$$P_3V_\text{i} = P_2V_\text{f} \quad \Rightarrow \quad V_\text{f} = \frac{P_3}{P_2}V_\text{i}$$

Next, use Pascal's second law to determine d. The bottom of the bell is at $y_1 = 0$; the water surface is at $y_3 = d$. Compare the pressure at the ocean surface P_3 to the pressure at the water surface inside the bell P_2:

$$P_2 = P_3 + \rho(y_3 - y_2)g$$

Solve and evaluate $V_\text{f} = \dfrac{P_3}{P_2}V_\text{i} = \dfrac{1.0 \times 10^5\ \text{N/m}^2}{2.0 \times 10^5\ \text{N/m}^2}V_\text{i} = \dfrac{1}{2}V_\text{i}$

Thus, the air volume inside the diving bell is half of what it was before entering the water. The bell is therefore half full of water, which means the height of the water level inside is

$$h = \frac{1}{2}(4.0\ \text{m}) = 2.0\ \text{m} = y_2$$

(CONTINUED)

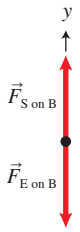
Rearrange Pascal's second law to solve for the position y_2 of the water level inside the bell:

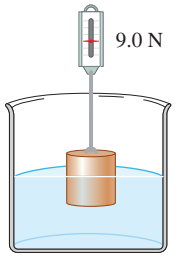
$$y_2 = 2.0\text{ m} = y_3 - \frac{P_2 - P_3}{\rho g} = d - \frac{(2.0 \times 10^5\text{ Pa} - 1.0 \times 10^5\text{ Pa})}{(1027\text{ kg/m}^3)(9.8\text{ N/kg})}$$
$$= d - 10\text{ m}$$

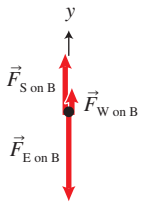
Thus, $d = 2.0\text{ m} + 10\text{ m} = 12\text{ m}$. The position of the bottom of the bell is 12 m below the ocean's surface.

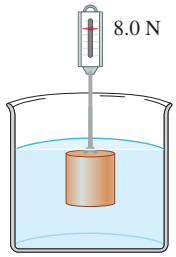
Try it yourself Suppose the air pressure in the bell is 3.0 atm. In this case, how high is the water in the bell, and how deep is the bottom of the bell?

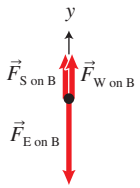
Answer The water is 2.7 m high in the bell (there is 1.3 m of air at the top), and the bottom of the bell is 23 m below the ocean's surface.



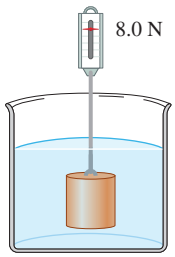


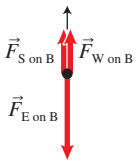






REVIEW QUESTION 13.4 What does it mean if atmospheric pressure is 760 mm Hg?





13.5 Buoyant force

Pascal's first law tells us that pressure changes in one part of a fluid result in pressure changes in other parts. Pascal's second law describes how the pressure in a fluid varies depending on the depth in the fluid. Do these laws explain why some objects float and others sink? Consider Observational Experiment **Table 13.4**.

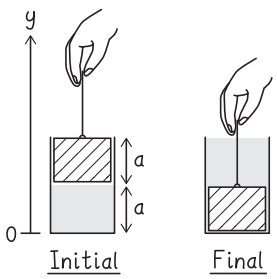
OBSERVATIONAL EXPERIMENT TABLE 13.4  **Effect of depth of submersion on a steel block suspended in water**

VIDEO OET 13.4

Observational experiment		Analysis	
Experiment 1. Hang a 1.0-kg block from a spring scale. The force that the scale exerts on the block balances the downward force that Earth exerts on the block ($mg = (1.0\text{ kg})(9.8\text{ N/kg}) = 9.8\text{ N}$).		Force diagram for the block B:	
Experiment 2. Lower the block into a container of water, so it is partially submerged. The water level rises. The reading of the scale decreases.		We explain the decreased reading on the scale by the water pushing upward a little on the block.	
Experiment 3. Lower the same block into the container of water to the point where the block is completely submerged. As the water level rises, the reading of the scale decreases.		The upward force exerted by the water increases.	

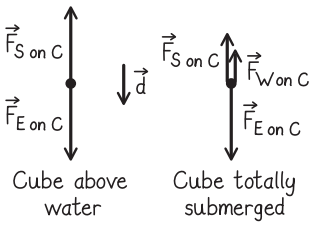
Observational experiment	Analysis
Experiment 4. Lower the block into the container of water so that the block is completely submerged near the bottom. The water level and the reading of the scale do not change. 	The upward force exerted by the water does not change once it is completely submerged. 

Patterns



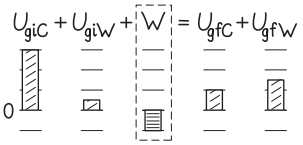
We notice two effects:

1. The level of the water in the container rises as more of the block is submerged in the water.
2. The scale reading decreases as more of the block is submerged. The water exerts an upward force on the block. The magnitude of this force depends on how much of the block is submerged. After it is totally submerged, the force does not change, even though the depth of submersion changes.



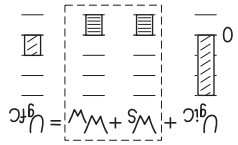
CONCEPTUAL EXERCISE 13.6 Qualitative force and energy analysis for an object in a fluid

You hang a solid metal cube (with side a) by a string over a rectangular container filled with water up to height a. The cube barely fits inside the container. Starting when the cube is just above the water in the container, you very slowly lower the cube into the water until it is totally submerged. Represent this process by drawing force diagrams for the cube when it is above the water and when it is totally submerged. Also draw an energy bar chart for the cube, Earth, and the water as the system for those states.



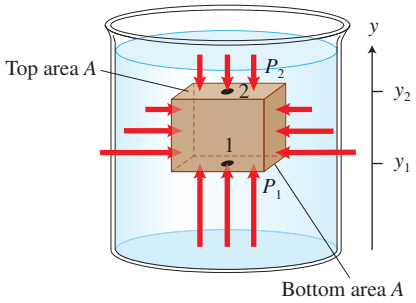
Sketch and translate We draw a sketch of the situation; the system and the initial and final states are specified in the problem statement. The submerged cube displaces water that is now above the cube. The volumes of the cube and water are the same, but the water has less mass due to its smaller density.

Simplify and diagram Because you are moving the cube very slowly, we can neglect the kinetic energy of the cube and the water in this process. We also assume that the cube has no acceleration during this motion and all friction effects are negligible. On the force diagrams we show the three forces exerted by the three objects with which the cube interacts: Earth, the water, and the string. Because there is no acceleration, the sum of the forces is zero.



The string does negative work on the cube because the force it exerts on the cube points opposite to the cube's displacement. Given that both water and the cube interact with Earth, we consider the gravitational potential energies of these interactions separately. We take zero gravitational potential energy to be at the bottom of the container. In the initial state, the system has initial gravitational potential energy due to the location of the cube and water. The gravitational potential energy of cube-Earth interaction decreases as the cube moves down; the gravitational potential energy of water-Earth interaction increases as some water moves up (being replaced by the cube). However, the total gravitational potential energy of the system must decrease due to the negative work done by the string.

Try it yourself Draw the bar charts for the two states, choosing the cube and Earth as a system.



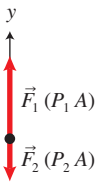
Answer

In Table 13.4, after the block is completely submerged, the scale reads 8.0 N instead of 9.8 N. Evidently, the water exerts a 1.8-N upward force on the block. What is the mechanism responsible for this force?

FIGURE 13.12 A fluid exerts an upward buoyant force on the block.

(a) The force exerted on the block by the fluid below is greater than the force exerted by the fluid above.

(b) The upward force of the fluid on the bottom surface is greater than the downward force of the fluid on the top surface.



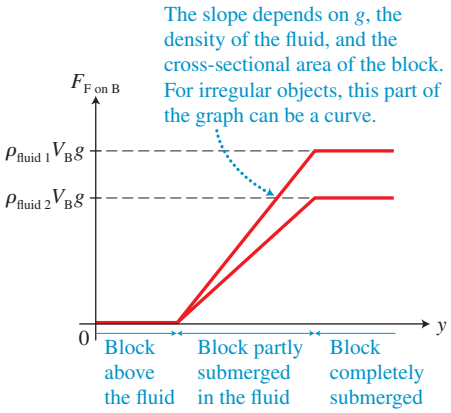


FIGURE 13.13 Buoyant force dependence on the depth of the object and the density of the fluid.

The magnitude of the force the fluid exerts on a submerged object

Consider *only* the fluid forces exerted on the block shown in **Figure 13.12a**. The fluid pushes inward on the block from all sides, including the top and the bottom. The forces exerted by the fluid on the vertical sides of the block cancel, since the pressure at a specific depth is the same magnitude in all directions.

What about the fluid pushing down on the top and up on the bottom of the block? The pressure is greater at elevation y_1 at the bottom of the block than at elevation y_2 at the top surface of the block. Consequently, the force exerted by the fluid pushing up on the bottom of the block is greater than the force exerted by the fluid pushing down on the top of the block. Arrows in Figure 13.12b represent the forces that the fluid exerts on the top and bottom of the block. The vector sum of these two fluid forces always points up and is called a buoyant force $\vec{F}_{\text{F on B}}$ (fluid on block).

To calculate the magnitude of the upward buoyant force $F_{\text{F on B}}$ exerted by the fluid on the block, we use Eq. (13.3) to determine the pressure P_1 of the fluid on the bottom surface of the block compared to the pressure P_2 of the fluid on the top surface (see Figure 13.12):

$$P_1 = P_2 + \rho_{\text{fluid}}(y_2 - y_1)g$$

The magnitudes of the forces exerted by the fluid on the top and on the bottom of the block are the products of the pressure P and the area A of the top and bottom surfaces of the block:

$$P_1A = P_2A + \rho_{\text{fluid}}(y_2 - y_1)Ag$$

or

$$F_1 = F_2 + \rho_{\text{fluid}}(y_2 - y_1)Ag$$

The volume of the block is

$$V_{\text{B}} = A(y_2 - y_1)$$

where A is the cross-sectional area of the block and $(y_2 - y_1)$ is its height. Substitute this volume into the above force equation and rearrange it to get an expression for the magnitude of the total upward **buoyant force** $F_{\text{F on B}}$ that the fluid exerts on the block (the object of interest):

$$F_{\text{F on B}} = F_1 - F_2 = \rho_{\text{fluid}}\, gV$$

Note that for a totally submerged block, V is the volume of the block. However, when it is partially submerged, V is the volume of the submerged part.

We can now understand the results of the experiments in Table 13.4. When submerging the block further into the water, the scale reading decreased because the buoyant force was increasing. The scale reading stopped changing after the block was completely under the water. Once completely underwater, the submerged volume did not change; the upward buoyant force exerted by the fluid on the block remained constant. Fluids of different densities exert different upward forces on the same object submerged to the same depth (**Figure 13.13**).

Archimedes' principle—the buoyant force A stationary fluid exerts an upward buoyant force on an object that is totally or partially submerged in the fluid. The magnitude of the force is the product of the fluid density ρ_{fluid}, the volume $V_{\text{displaced}}$ of the fluid that is displaced by the object, and the gravitational constant g:

$$F_{\text{F on O}} = \rho_{\text{fluid}}V_{\text{displaced}}g = \rho_{\text{fluid}}V_{\text{subm}}g \qquad (13.5)$$

TIP The derivation of Eq. (13.5) was for a solid cube, but the result applies to objects of any shape, though calculus is needed to establish that.

For simplicity, we will always use the volume of the submerged part of the object in our calculations and label it V_{subm}. Because $\rho_{\text{fluid}} V_{\text{displaced}} = m_{\text{displaced fluid}}$, we see that **the buoyant force is equal in magnitude to the force that Earth exerts on the amount of fluid displaced by the object.** However, the natures of these two forces are different. Earth exerts a gravitational force at a distance; the buoyant force is a contact force.

REVIEW QUESTION 13.5 Why does a fluid exert an upward force on an object submerged in it?

13.6 Skills for analyzing static fluid problems

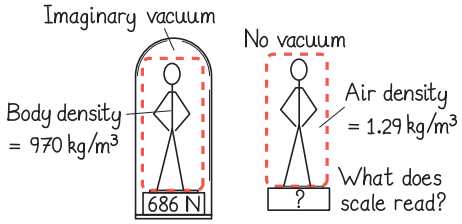
In this section we adapt our problem-solving strategy to analyze processes involving static fluids.

PROBLEM-SOLVING STRATEGY 13.1 Analyzing situations involving static fluids

Sketch and translate

- Make a labeled sketch of the situation and choose the system of interest. If applicable, decide on the initial and final states.
- Include all known information in the sketch and indicate the unknown(s) you wish to determine.

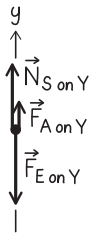
Simplify and diagram



- Indicate any assumptions you are making.
- Identify objects outside the system that interact with it.
- Construct a force diagram for the system, including a vertical coordinate axis. The buoyant force is just one of the forces included in the diagram.
- Construct a bar chart or any other graphical representation that might help solve the problem.

EXAMPLE 13.7 Buoyant force exerted by air on a human

Suppose your mass is 70.0 kg and your density is 970 kg/m^3. If you could stand on a scale in a vacuum chamber on Earth's surface, the reading of the scale would be $mg = (70.0\text{ kg})(9.80\text{ N/kg}) = 686\text{ N}$. What will the scale read when you are completely submerged in air of density 1.29 kg/m^3?



You are the system.

The scale reads 686 N when in a vacuum. Your density is 970 kg/m^3 and the density of air is 1.29 kg/m^3. What does it read when you are submerged in air?

Assume that the air density is uniform.

Three objects exert forces on you. Earth exerts a downward gravitational force $F_{\text{E on Y}} = mg = 686\text{ N}$. The air exerts an upward buoyant force $F_{\text{A on Y}} = \rho_{\text{air}} g V_{\text{Y}}$. The scale exerts an unknown upward normal force of magnitude $N_{\text{S on Y}}$.

(CONTINUED)

Represent mathematically

- Use the force diagram to help apply Newton's second law in component form.
- Use the energy bar chart to calculate work and energy if needed.
- Use the expression for the buoyant force and the definitions of pressure and density if needed; sometimes you might need the ideal gas law.

The y-component form of Newton's second law for your body with zero acceleration is (assuming the upward direction as positive)

$$0 = N_{\text{S on Y}} + F_{\text{A on Y}} + (-F_{\text{E on Y}})$$

or

$$N_{\text{S on Y}} = +F_{\text{E on Y}} - F_{\text{A on Y}}$$

The buoyant force that the air exerts on your body has magnitude $F_{\text{A on Y}} = \rho_{\text{air}} V_{\text{Y}} g$. The volume of your body is $V_{\text{Y}} = (m/\rho_{\text{body}})$. The magnitude of the buoyant force that the air exerts on you is

$$F_{\text{A on Y}} = \rho_{\text{air}}\left(\frac{m}{\rho_{\text{body}}}\right)g = mg\left(\frac{\rho_{\text{air}}}{\rho_{\text{body}}}\right)$$

Thus the reading of the scale should be:

$$N_{\text{S on Y}} = mg - mg\left(\frac{\rho_{\text{air}}}{\rho_{\text{body}}}\right)$$

Solve and evaluate

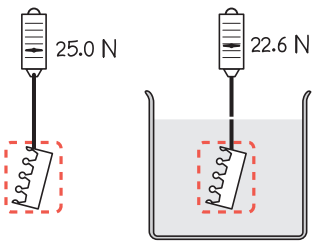
- Insert the known information and solve for the desired unknown.
- Evaluate the final result in terms of units, reasonable magnitude, and whether the answer makes sense in limiting cases.

$$N_{\text{S on Y}} = +686\ \text{N} - (686\ \text{N})\frac{1.29\ \text{kg/m}^3}{970\ \text{kg/m}^3} = 685\ \text{N}$$

According to Newton's third law, the force that you exert on the scale $N_{\text{Y on S}}$ is equal in magnitude to the force the scale exerts on you.

The reading of the scale is actually 0.1% less when you step on the scale in air—not a big deal. We can usually neglect air's buoyant force. Notice that overall the atmospheric air pushes up on objects, not down.

Try it yourself What will the scale read if you weigh yourself in a swimming pool with your body completely submerged?

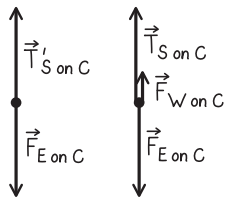


Answer 0 N. Because you are less dense than water, the buoyant force exerted by the water on you will completely support you, and the scale will not push upward on you at all.

We will use these strategies to analyze several more situations. In the next example, it might not be obvious how to arrive at the answer to the question with the information provided. Following the suggested problem-solving routine will help you arrive at a solution.

EXAMPLE 13.8 Is the crown made of gold?

You need to determine if a crown is made from pure gold or some less valuable metal. From Table 13.1 you know that the density of gold is 19,300 kg/m^3. You find that the force that a string attached to a spring scale exerts on the crown is 25.0 N when the crown hangs in air and 22.6 N when the crown hangs completely submerged in water.



Sketch and translate We draw a sketch of the situation and label the givens. If you could measure the mass m_{C} of the crown and its volume V_{C}, you could calculate the density $\rho_{\text{C}} = m_{\text{C}}/V_{\text{C}}$ of the crown—it should be 19,300 kg/m^3.

You can determine the mass of the crown easily from the measurement of the scale when the crown hangs in air. But how can you determine the volume from the given information? Crowns have irregular shapes, and it would be difficult to determine its volume by simple measurements and calculations.

Simplify and diagram Let's follow the recommended strategy and see what happens. First, we draw force diagrams for the crown hanging in air and again when hanging in water. When the crown is in air, the upward force exerted by the string attached to the spring scale balances the downward force exerted by Earth. We ignore the buoyant force that air exerts on the crown when hanging in air, since it will be very small in magnitude compared with the other forces exerted on the crown.

When the crown is in water, the upward force exerted by the string (the force measured by the scale) and the upward buoyant force that the water exerts on the crown combine to balance the downward gravitational force that Earth exerts on the crown.

Represent mathematically Since the crown is in equilibrium, the forces exerted on it must add to zero in both cases. When the crown is hanging in air, the vertical component form of Newton's second law is

$$0 = \Sigma F_y = T'_{\text{S on C}} + (-F_{\text{E on C}})$$

where $T'_{\text{S on C}}$ is the 25.0-N string tension force exerted on the crown when it is suspended in air. Thus,

$$F_{\text{E on C}} = m_{\text{C}}g = 25.0\ \text{N}$$

or

$$m_{\text{C}} = \frac{25.0\ \text{N}}{9.8\ \text{N/kg}} = 2.55\ \text{kg}$$

The vertical component form of Newton's second law when the crown hangs in water becomes (the upward direction is positive):

$$\Sigma F_y = T_{\text{S on C}} + F_{\text{W on C}} + (-F_{\text{E on C}}) = 0$$

where $T_{\text{S on C}} = 22.6$ N is the magnitude of the string tension force, and the buoyant force that the water exerts on the crown is $F_{\text{W on C}} = \rho_{\text{W}} V_{\text{C}}\, g$. Substituting in the above, we get

$$T_{\text{S on C}} + \rho_{\text{W}} V_{\text{C}} g - m_{\text{C}} g = 0$$

Solve and evaluate We see now that the last equation can be used to determine the volume of the crown:

$$V_{\text{C}} = \frac{m_{\text{C}}g - T_{\text{S on C}}}{\rho_{\text{W}} g} = \frac{25.0\ \text{N} - 22.6\ \text{N}}{(1000\ \text{kg/m}^3)(9.8\ \text{N/kg})} = 0.000245\ \text{m}^3$$

We now know the crown mass and volume and can calculate its density:

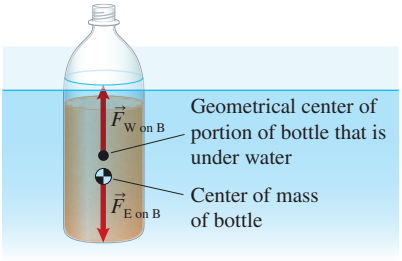
$$\rho = \frac{m}{V} = \frac{2.55\ \text{kg}}{0.000245\ \text{m}^3} = 10{,}400\ \text{kg/m}^3$$

Oops! Since 10,400 kg/m^3 is much less than the 19,300 kg/m^3 density of gold, the crown is not made of pure gold. The goldsmith must have combined the gold with some less expensive metal.

Try it yourself What is the density of the crown if the scale reads 0 when submerged in water?

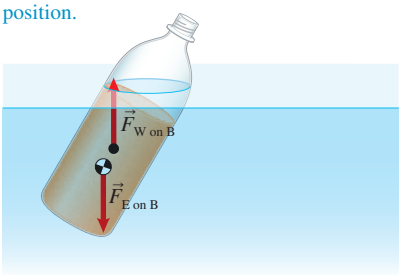
Answer 1000 kg/m^3

REVIEW QUESTION 13.6 Two objects have the same volume, but one is heavier than the other. When they are completely submerged in oil, on which one does the oil exert a greater buoyant force?



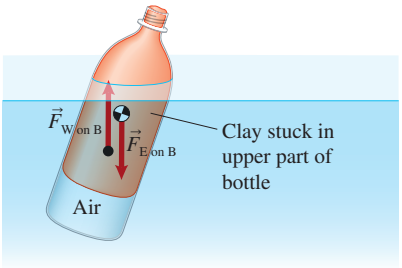
13.7 Ships, balloons, climbing, and diving

As we learned in Section 13.1, whether an object floats or sinks depends on its density relative to the density of the fluid. The reason for this lies in the interactions of the object with the fluid and Earth. Specifically, the magnitude of the buoyant force is $F_{\text{F on O}} = \rho_{\text{fluid}} V_{\text{subm}}\, g$, and the magnitude of the force exerted by Earth is $F_{\text{E on O}} = \rho_{\text{object}} V_{\text{object}}\, g$. These forces are exerted in the opposite directions. The relative densities of the fluid and the object and consequently the relative magnitudes of the forces determine what happens to the object when placed in the fluid.



- If the object's density is less than that of the fluid $\rho_{\text{object}} < \rho_{\text{fluid}}$, then $\rho_{\text{object}} V_{\text{object}}\, g < \rho_{\text{fluid}} V_{\text{object}}\, g$; the object floats *partially* submerged since the buoyant force can balance the gravitational force with less than the entire object below the surface of the fluid.
- If the densities are the same $\rho_{\text{object}} = \rho_{\text{fluid}}$, then $\rho_{\text{object}} V_{\text{object}}\, g = \rho_{\text{fluid}} V_{\text{object}}\, g$; the sum of the forces exerted on the object is zero and it remains wherever it is placed totally submerged at any depth in the fluid.
- If the object is denser than the fluid $\rho_{\text{object}} > \rho_{\text{fluid}}$, then $\rho_{\text{object}} V_{\text{object}}\, g > \rho_{\text{fluid}} V_{\text{object}}\, g$; the magnitude of the gravitational force is always greater than the magnitude of the buoyant force. The object sinks until it reaches the bottom of the container.

FIGURE 13.14 Making a bottle float with stable equilibrium.



(a) Bottle partially filled with sand floats upright if the center of mass is below the geometrical center of bottle.

(b) If the bottle is tipped, torques due to forces exerted on the bottle return it to the upright position.

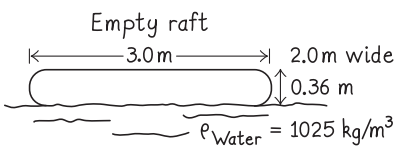
(c) If this bottle tips slightly, torques due to forces exerted on the bottle cause it to overturn.

These cases show that by changing the average density of an object relative to the density of the fluid, the object can be made to float or sink in the same fluid. In this section we investigate this phenomenon and its many practical applications.

Building a stable ship

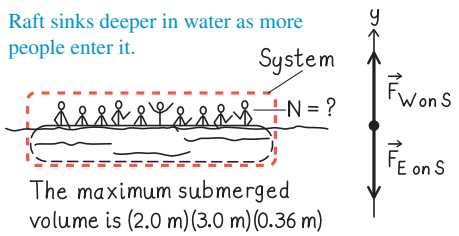
For years ships were made of wood. In the middle of the 17th century, people decided to try building metal ships. Many thought that this idea was absurd: iron is denser than water and an iron boat would certainly sink. In 1787 British engineer John Wilkinson succeeded in building the first iron ship that did not sink. Since the middle of the 19th century, large ships have been made primarily of steel, which is less dense than iron but much denser than water. These ships can float because part of the volume of a ship is filled with air, which reduces the average density of the ship to a density lower than that of water.

Making a ship or a raft float is only part of the challenge of building watercraft. Another problem is to maintain stable equilibrium for the ship, allowing it to right itself if it tilts to one side due to wind or rough seas. Refresh your knowledge of stable equilibrium (Section 8.6) before you read on.



Consider a floating bottle partially filled with sand. Earth exerts a gravitational force at the center of mass of the bottle (**Figure 13.14a**). The buoyant force exerted by the water on the bottle is effectively exerted at the geometrical center of the part of the bottle that is underwater, which equals the center of mass of the displaced water. If this point is above the center of mass of the bottle, then any slight tipping causes these forces to produce a torque that attempts to return the bottle to an upright position (see Figure 13.14b). However, if the geometrical center of the part of the bottle that is underwater is below the center of mass of the bottle, slight tipping causes the gravitational force to produce a torque that enhances the tipping—unstable equilibrium (Figure 13.14c).

Although ships are more complicated than water bottles filled with sand, it is important to load a ship in such a way that when it begins to heel and one side of the hull begins to rise from the water, the center of mass of the displaced water is above the center of mass of the ship. This is why ships have their cargo stored at the bottom.



EXAMPLE 13.9 **Should we take this trip?**

The top of an empty life raft of cross-sectional area 2.0 m × 3.0 m is 0.36 m above the waterline. How many 75-kg passengers can the raft hold before water starts to flow over its top? The raft is in seawater of density 1025 kg/m^3.

Sketch and translate We make a sketch of the unloaded raft. As people get on the raft, it sinks deeper into the water, and the upward buoyant force increases until the raft reaches a maximum submerged volume, when the maximum number of people are on board. The maximum submerged volume is $V_{\text{subm}} = 2.0\text{ m} \times 3.0\text{ m} \times 0.36\text{ m} = 2.16\text{ m}^3$. We need to determine the maximum buoyant force the seawater can exert on the raft and then decide how to convert this into the number of passengers the raft can hold. The raft and the passengers are our system of interest.

Simplify and diagram We have no information about the mass of the raft; thus we will assume it is negligible. We draw a sketch of the filled raft and a force diagram for the raft with passengers (the system). The vertical axis points up. There are two forces exerted on the system: the upward force exerted by the water $\vec{F}_{\text{W on S}}$ of magnitude $\rho_{\text{water}} g V_{\text{subm}}$ and the downward force exerted by Earth $\vec{F}_{\text{E on S}}$. The magnitude of the force Earth exerts on N people is $N_{\text{people}} m_{\text{person}} g$. As the system is in equilibrium, the net force exerted on it is zero.

Represent mathematically Using the upward direction as positive, apply the vertical component form of Newton's second law:

$$\Sigma F_y = F_{\text{W on S}} + (-F_{\text{E on S}}) = 0$$
$$\rho_{\text{water}} g V_{\text{subm}} - N_{\text{people}} m_{\text{person}} g = 0$$

Assuming that all people have the same mass, we find the number of people:

$$N_{\text{people}} = \frac{\rho_{\text{water}} V_{\text{subm}} g}{m_{\text{person}} g} = \frac{\rho_{\text{water}} V_{\text{subm}}}{m_{\text{person}}}$$

Solve and evaluate

$$N_{\text{people}} = \frac{\rho_{\text{water}} V_{\text{subm}}}{m_{\text{person}}}$$
$$= \frac{(1025 \text{ kg/m}^3)(0.36 \text{ m} \times 2.0 \text{ m} \times 3.0 \text{ m})}{75 \text{ kg}} = 29.5$$

The raft can precariously hold 29 passengers, which is a reasonable number. The number is inversely proportional to the mass of a person. This makes sense—the heavier the people, the fewer of them the raft should hold. The units, dimensionless, also make sense. We assumed that the raft has negligible mass. If we take the mass into account, the number of people will be smaller.

Try it yourself Suppose that 10 people of average mass 80 kg entered the raft. Now how far would the water line be from the top of the raft?

Answer The raft would sink 0.13 m into the water, and the water line would be 0.23 m below the top of the raft.

Ballooning

Balloons used for transportation are filled with hot air. Why hot air? The density of 100 °C air is 0.73 times the density of 0 °C air. Thus, balloonists can adjust the average density of the balloon (the balloon's material, people, equipment, etc.) to match the density of air so that the balloon can float at any location in the atmosphere (up to certain limits). A burner under the opening of the balloon regulates the temperature of the air inside the balloon and hence its volume and density. This allows control over the buoyant force that the outside cold air exerts on the balloon. The same approach that we used in Example 13.9 allows us to predict that a balloon with radius of 5.0 m and a mass of 20.0 kg filled with air at the temperature of 100 °C can carry about 160 kg (three slim 53-kg people or two medium-mass 80-kg people). This is not a heavy load.

At one time, hydrogen was used in closed balloons instead of air. The density of hydrogen is 1/14 times the density of air. Unfortunately, hydrogen can burn explosively in the presence of oxygen. The hydrogen-filled Hindenburg, a German airship, caught fire and exploded in 1937, killing 36 people (see **Figure 13.15**). Balloonists then turned to helium—an inert gas that does not interact readily with other types of atoms.

FIGURE 13.15 The Hindenburg explosion.

Effects of altitude on humans

Table 13.5 on the next page shows that atmospheric pressure decreases with altitude. Therefore, climbers and balloonists have to guard against altitude sickness, caused by the low pressure and lack of oxygen. Below 3000 m, altitude has little effect on performance. Between 3000 m and 4600 m, climbers experience compensated hypoxia—increased heart and breathing rates. Between 4600 m and 6000 m, manifest hypoxia sets in. Heart and breathing rates increase dramatically, and cognitive and sensory function and muscle control decline. Climbers may feel lethargy and euphoria and even experience hallucinations. Between 6000 m and 8000 m, climbers undergo critical hypoxia, characterized by rapid loss of muscular control, loss of consciousness, and possibly death.

These symptoms were exhibited clearly on April 15, 1875 by three French balloon pioneers attempting to set an altitude record. They carried bags of oxygen with them, but as their elevation increased, slowly lost the mental awareness needed to use the bags. Instruments indicate that the balloon reached a maximum elevation of 8600 m twice. During the second time, two of the balloonists died. The third lost consciousness but survived.

TABLE 13.5 Pressure of air and pressure due to oxygen in the air (called partial pressure) at different elevations

Location	Elevation (m)	P_{air} (atm)	P_{oxygen} (atm)
Sea level	0	1.0	0.21
Mount Washington	1917	0.93	0.18
Pikes Peak	4301	0.59	0.12
Mount McKinley	6190	0.47	0.10
Mount Everest	8848	0.34	0.07
Jet travel	12,000	0.23	0.05

Scuba diving

The sport of scuba diving depends on an understanding of fluid pressure and buoyant force to avoid cases of excess internal pressure, oxygen overload, and decompression sickness.

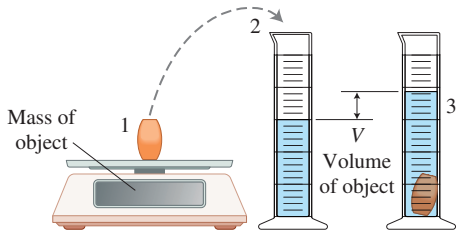
Assuming that the surface area of your body is about 2 m^2, the air exerts a 200,000-N force (about 20 tons) on the surface of your body. Fortunately, fluids inside the body push outward and balance the force exerted by the outside air. For example, the pressure inside your lungs is approximately atmospheric pressure. What would happen if the fluid pressure on the inside remained constant while the pressure on the outside doubled or tripled? Would you be crushed, the way a can or barrel is crushed by outside air pressure when the air pressure inside the can is much lower than the pressure outside (**Figure 13.16**)? Scuba divers face this problem.

We know that atmospheric pressure (1 atm) is equivalent to the pressure of a 10-m column of water. Therefore, at depth $d = 10$ m, the water pressure is 2 atm. At 40 m below the water surface, the pressure is about 5 atm. This would surely be a problem for a scuba diver if the internal pressure were only 1 atm!

To avoid this problem, divers breathe compressed air. While moving slowly downward, a diver adjusts the pressure outlet from the compressed air tank in order to accumulate gas from the cylinder into her lungs and subsequently into other body parts, increasing the internal pressure to balance the increasing external pressure. If a diver returns to the surface too quickly, the great gas pressure in the lungs can force bubbles of gas into the bloodstream. These bubbles can behave like blood clots, blocking blood flow to the brain and possibly causing death. Blood vessels can rupture if the pressure difference between the inside and outside of the vessel is too great. Thus, a diver rises to the surface slowly so that pressure changes gradually and bubbles of gas do not form. This gradual process is called *decompression*.

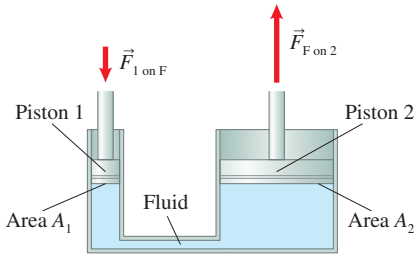
When humans travel to dangerous environments (mountaintops, the deep sea, or outer space), physics intersects with human physiology. A careful understanding of gases, liquids, and the effects of changing pressures on the human body is needed to allow humans to survive in these places. As we explore the universe, we will need to learn to adapt to ever more challenging environments.

FIGURE 13.16 External air pressure collapses an evacuated can.



When air is pumped out of a can, outside air pressure causes it to collapse.

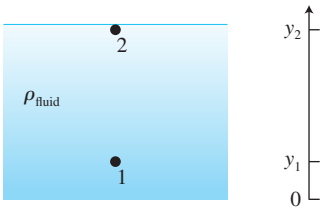
REVIEW QUESTION 13.7 A ship's waterline marks the maximum safe depth of the ship in the water when it has a full cargo. An empty ship is at the dock with its waterline somewhat above the water level. How could you estimate its maximum cargo?



Summary

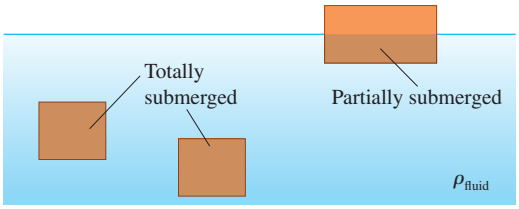
Density ρ The ratio of the mass m of a substance divided by the volume of that substance. (Section 13.1)

$$\rho = \frac{m}{V} \qquad \text{Eq. (13.1)}$$



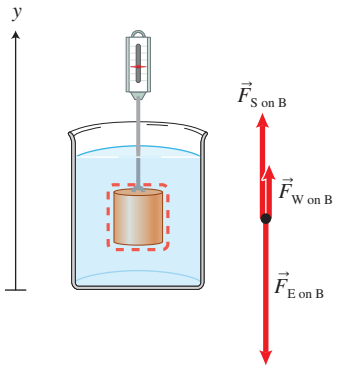
Pascal's first law—hydraulic lift An increase in the pressure in one part of an enclosed fluid increases the pressure throughout the fluid. In a hydraulic lift, a small force F_1 exerted on a small piston of area A_1 can cause a large force F_2 to be exerted on a large piston of area A_2. (Section 13.2)

For a hydraulic lift:



$$F_{\text{F on 2}} = PA_2 = (A_2/A_1)\, F_{1 \text{ on F}} \qquad \text{Eq. (13.2)}$$

Pascal's second law—variation of pressure with depth On a vertical upward-pointing y-axis, the pressure of a fluid P_1 at position y_1 depends on the pressure P_2 at position y_2 and on the density of the fluid. (Section 13.3)

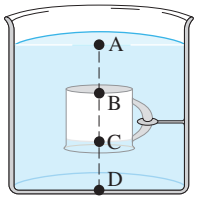


$$P_1 = P_2 + \rho_{\text{fluid}}(y_2 - y_1)g \qquad \text{Eq. (13.3)}$$

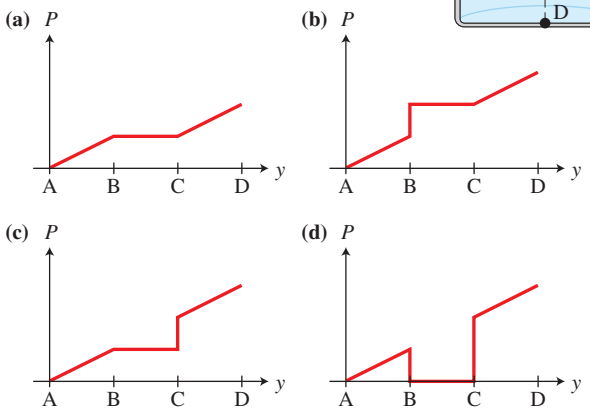
Buoyant force A fluid exerts an upward-pointing buoyant force on an object totally or partially immersed in the fluid. The force depends on the density of the fluid and on the volume of the fluid displaced. Once the object is totally submerged, the buoyant force does not change. (Section 13.5)

$$F_{\text{F on O}} = \rho_{\text{fluid}} V_{\text{displaced}} g \qquad \text{Eq. (13.5)}$$

Newton's second law Use the standard problem-solving strategies with this law (sketches, force diagrams, math descriptions) to find some unknown quantity. The problems often involve the buoyant force, pressure, and density. (Section 13.6)



$$a_y = \frac{\Sigma F_y}{m} \qquad \text{Eq. (3.7}y\text{)}$$



Questions

Multiple Choice Questions

1. Rank in increasing order the pressure that the *italicized objects* exert on the surface.
   I. A person standing with *bare feet* on the floor
   II. A person in *skis* standing on snow
   III. A person in *Rollerblades* standing on a road
   IV. A person in *ice skates* standing on ice
   (a) I, II, III, IV (b) IV, III, I, II (c) IV, III, II, I
   (d) III, II, IV, I (e) II, I, III, IV
2. Choose a device that reduces the pressure caused by a force.
   (a) Scissors (b) Knife (c) Snowshoes
   (d) Nail (e) Syringe
3. What does it mean if the density of a material equals 2000 kg/m^3?
   (a) The mass of the material is 2000 kg.
   (b) The volume of the material is 1 m^3.
   (c) The ratio of the mass of any amount of this material to the volume is equal to 2000 kg/m^3.
4. An upside-down mug with some air trapped in it is fixed under water, as shown in **Figure Q13.4**. Which qualitative pressure-versus-position graph correctly shows how the gauge pressure changes along the dashed line through the mug from A to D?

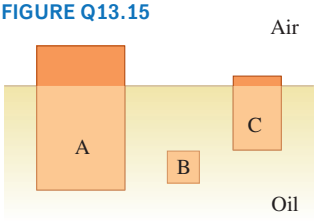


FIGURE Q13.4

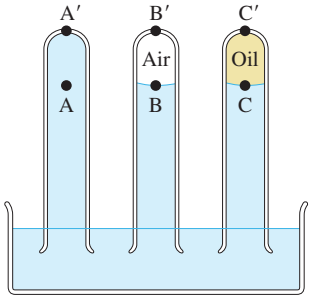
5. If you hold a cylinder vertically, what is the net force exerted by the atmospheric pressure on it?
   (a) Downward (b) Upward (c) Zero
6. How do we know that a fluid exerts an upward force on an object submerged in the fluid?
   (a) Fluid pushes on the object in all directions.
   (b) The reading of a scale supporting the object when submerged in the fluid is less than when not in the fluid.
   (c) The fluid pressure on the bottom of the object is greater than the pressure on the top.
   (d) Both b and c are correct.
7. When you suspend an object from a spring scale, it reads 15 N. Then you place the same object and scale under a vacuum jar and pump out the air. What happens to the reading of the scale?
   (a) It increases slightly.
   (b) It decreases slightly.
   (c) It says the same.
   (d) Don't have enough information to answer
8. Why can't a suction pump lift water higher than 10.3 m?
   (a) Because it does not have the strength to pull up higher
   (b) Because the atmospheric pressure is equal to the pressure created by a 10.3-m-high column of water
   (c) Because suction pumps are outdated lifting devices
   (d) Because most suction cups have an opening to the bulb that is too narrow
9. If Torricelli had a wider tube in his mercury barometer, what would the height of the mercury column in the tube do?
   (a) Decrease (b) Increase (c) Stay the same
10. A wooden cube is floating in a fish tank that is filled with water. Imagine that you take this setup to a space station on the Moon. Air pressure and temperature inside the station are similar to conditions on Earth. After bringing the setup from Earth to the space station, you will observe that (choose all correct statements)
    (a) the amount of water displaced by the cube increases.
    (b) the amount of water displaced by the cube decreases.
    (c) the amount of water displaced by the cube stays the same.
    (d) the buoyant force exerted on the cube increases.
    (e) the buoyant force exerted on the cube decreases.
    (f) the buoyant force exerted on the cube stays the same.
    (g) the pressure at the bottom of the fish tank is about 1/6 of the value on Earth.
    (h) the pressure at the bottom of the fish tank is significantly less than 1/6 of the value on Earth.
    (i) the pressure at the bottom of the fish tank is slightly less than the value on Earth.
    (j) the pressure at the bottom of the fish tank is the same as on Earth.
11. Two identical beakers with the same amount of water sit on the arms of an equal arm balance. A wooden block floats in one of them. What does the scale indicate?
    (a) The beaker with the block is heavier.
    (b) The beaker without the block is heavier.
    (c) The beakers weigh the same.
12. A piece of steel and a bag of feathers are suspended from two spring scales in a vacuum. Each scale reads 100 N. What happens when you repeat the experiment outside under normal conditions?
    (a) The scale with feathers reads more than the scale with steel.
    (b) The scale with feathers reads less that the scale with steel.
    (c) The scales have the same reading, but the reading is less than the reading in a vacuum.
13. A metal boat floats in a pool. What happens to the level of the water in the pool if the boat sinks?
    (a) It rises.
    (b) It falls.
    (c) It stays the same.
14. When a boat sails from seawater to fresh water, the buoyant force exerted on the boat
    (a) decreases. (b) increases. (c) stays the same.
15. Three blocks are floating in oil as shown in **Figure Q13.15**. Which block has the highest density?
    (a) A (b) B (c) C
    (d) All blocks have the same density.

FIGURE Q13.15



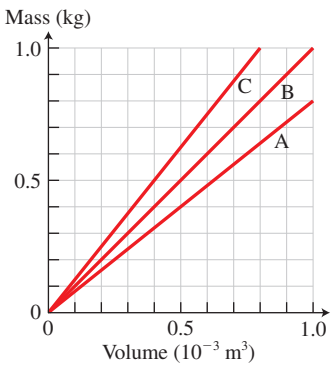
16. Three blocks are floating in oil as shown in Figure Q13.15. On which block does the oil exert the greatest buoyant force?
    (a) A (b) B (c) C
    (d) The oil exerts the same force on all of them.

Conceptual Questions

17. Describe a method to measure the density of a liquid.
18. How can you determine the density of air?
19. Design an experiment to determine whether air has mass.
20. Does air exert a net upward force or a net downward force on an object submerged in the air? How can you test your answer experimentally?
21. What causes the pressure that air exerts on a surface that is in the air?
22. Why, when you fill a teapot with water, is the water always at the same level in the teapot and in the spout?
23. What experimental evidence supports Pascal's first law?

24. Fill a plastic cup to the very top with water. Put a piece of paper on top of the cup so that the paper covers the cup at the edges and is not much bigger than the surface of the cup. Turn the cup and paper upside down (practice over the sink first) and hold the bottom of the cup (now on the top). Why doesn't the water fall out of the cup?
25. Why does a fluid exert a net upward force on an object submerged in the fluid?
26. Describe how you could predict whether an object will float or sink in a particular liquid without putting it into the liquid.
27. Why can you lift objects while in water that are too heavy to lift when in the air?
28. When placed in a lake, a solid object either floats on the surface or sinks. It does not float at some intermediate location between the surface and the bottom of the lake. However, a weather balloon floats at some intermediate distance between Earth's surface and the top of its atmosphere. Explain.
29. A flat piece of aluminum foil sinks when placed under water. Take the same piece and shape it so that it floats in the water. Explain why the method worked.
30. Ice floats in water in a beaker. Will the level of the water in the beaker change when the ice melts? Explain.
31. The density of ice at 0 °C is less than the density of water at 0 °C. How is this related to the existence of life on Earth?
32. How would you determine the density of an irregular-shaped unknown object if (a) it sinks in water and (b) it floats in water? List all the steps and explain the reasoning behind them.
33. Why do people sink in fresh water and in most seawater (if they do not make an effort to stay afloat) but do not sink in the Dead Sea?
34. A bucket filled to the top with water has a piece of ice floating in it. Will the pressure on the bottom of the bucket change when the ice melts? Explain.
35. Marjory thinks that the mass of a fluid above a certain level should affect the pressure at this level. Describe how you will test her idea.
36. You are holding a brick that is completely submerged in water. Draw a force diagram for the brick. Why does it feel lighter in water than when you hold it in the air?
37. A bucket filled with water has a piece of ice floating in it. Will the level of water rise when the ice melts? Justify your answer.
38. Explain qualitatively and quantitatively how we drink through a straw. Make sure you can account for the water going up the length of the straw.
39. Three test tubes are inverted in a Petri dish as shown in **Figure Q13.39**. The first is completely filled with water, the second has an air bubble at the top, and the third has oil at the same level as the air bubble. (a) Rank the pressures at points A, B, and C from largest to smallest. (b) Rank the pressures at points A′, B′, and C′ from largest to smallest.

FIGURE Q13.39



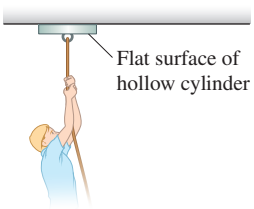
Problems

Below, BIO indicates a problem with a biological or medical focus. Problems labeled EST ask you to estimate the answer to a quantitative problem rather than derive a specific answer. Asterisks indicate the level of difficulty of the problem. Problems with no * are considered to be the least difficult. A single * marks moderately difficult problems. Two ** indicate more difficult problems.

13.1 Density

1. Determine the average density of Earth. What data did you use? What assumptions did you make?
2. * EST **Height of atmosphere** Use data for the normal pressure and the density of air near Earth's surface to estimate the height of the atmosphere, assuming it has *uniform* density. Indicate any additional assumptions you made. Are you on the low or high side of the real number?
3. EST A single-level home has a floor area of 200 m^2 with ceilings that are 2.6 m high. Estimate the mass of the air in the house.
4. * BIO A diet decreases a person's mass by 5%. Exercise creates muscle and reduces fat, thus increasing the person's density by 2%. Determine the percent change in the person's volume.
5. **Pulsar density** A pulsar, an extremely dense rotating star made of neutrons, has a density of 10^{18} kg/m^3. Determine the mass of a pulsar contained in a volume the size of your fist (about 200 cm^3).
6. Use the graph lines in **Figure P13.6** to determine the densities of the three liquids, A, B, and C, in SI units. If you place them in one container, how will they position themselves? How does the density of each liquid change as its volume increases? As its mass decreases? Compare the masses of the three liquids when they occupy the same volume. Compare the volumes of the three liquids when they have the same mass.

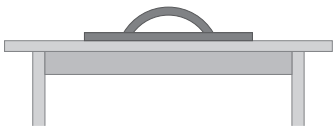
FIGURE P13.6



7. Imagine that you have gelatin cut into three cubes: the side of cube A is *a* cm long, the side of cube B is double the side of A, and the side of cube C is three times the side of A. Compare the following properties of the cubes: (a) density, (b) volume, (c) surface area, (d) cross-sectional area, and (e) mass.
8. An object made of material A has a mass of 90 kg and a volume of 0.45 m^3. If you cut the object in half, what would be the density of each half? If you cut the object into three pieces, what would be the density of each piece? What assumptions did you make?
9. You have a steel ball that has a mass of 6.0 kg and a volume of 3.0×10^{-3} m^3. How can this be?
10. * A material is made of molecules of mass 2.0×10^{-26} kg. There are 2.3×10^{29} of these molecules in a 2.0-m^3 volume. What is the density of the material?
11. You compress all the molecules described in Problem 13.10 into 1.0 m^3. Now what is the density of the material? What type of material could possibly behave this way?
12. * Bowling balls are heavy. However, some bowling balls float in water. Use available resources to find the dimensions of a bowling ball and explain why some balls float while others do not.
13. * EST Estimate the average density of a glass full of water and then the glass when the water is poured out (do not forget the air that now fills the glass instead of water).

13.2 Pressure inside a fluid

14. * Anita holds her physics textbook and complains that it is too heavy. Andrew says that her hand should exert no force on the book because the atmosphere pushes up on it and balances the downward pull of Earth on the book (the book's weight). Jim disagrees. He says that the atmosphere presses down on things and that is why they feel heavy. Who is correct? Approximately how large is the force that the atmosphere exerts on the bottom of the book? Why does this force not balance the force exerted by Earth on the book?

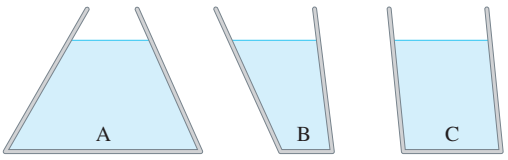


15. * The air pressure in the tires of a 980-kg car is 3.0×10^5 N/m^2. Determine the average area of contact of each tire with the road. Indicate any assumptions that you made.
16. * EST Estimate the pressure that you exert on the floor while wearing hiking boots. Now estimate the pressure under each heel if you change into high-heeled shoes. Indicate any assumptions you made.
17. **Hydraulic car lift** You are designing a hydraulic lift for a machine shop. The average mass of a car it needs to lift is about 1500 kg. What should be the specifications on the dimension of the pistons if you wish to exert a force on a smaller piston of not more than 500 N? How far down will you need to push the piston in order to lift the car 30 cm?
18. EST **Force of air on forehead** Estimate the force that air exerts on your forehead. Describe the assumptions you made.
19. * EST A 30-cm-diameter cylindrical iron plunger is held against the ceiling, and the air is pumped from inside it. A 72-kg person hangs by a rope from the plunger (Figure P13.19). List the quantities that you can estimate about the situation and estimate them. Make assumptions if necessary.

FIGURE P13.19

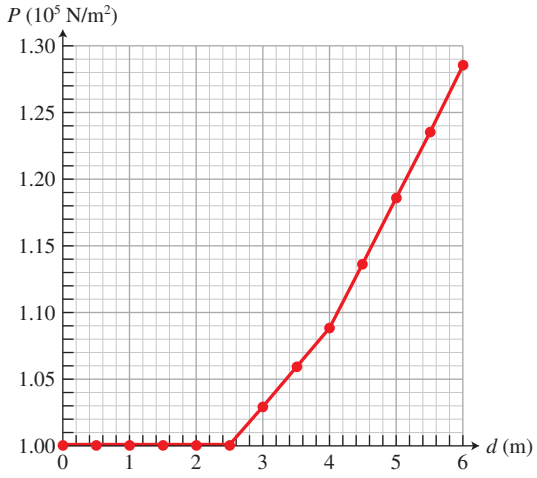
20. You have a rubber pad with a handle attached to it (Figure P13.20). If you press the pad firmly on a smooth table, it is impossible to lift it off the table. Why? What force would you need to exert on the handle to lift it? The surface area of the pad is 0.023 m^2.

FIGURE P13.20



21. * EST **Toy bow and arrow** A child's toy arrow has a suction cup on one end. When the arrow hits the wall, it sticks. Draw a force diagram for the arrow stuck on the wall and estimate the magnitudes of the forces exerted on it when it is in equilibrium. The mass of the arrow is about 10 g. Why are the words "suction cup" not appropriate?

13.3 Pressure variation with depth



22. * **Pressure on the Titanic** The Titanic rests 4 km (2.5 miles) below the surface of the ocean. What physical quantities can you determine using this information?
23. You have three reservoirs (Figure P13.23). Rank the pressures at the bottom of each and explain your rankings. Then rank the net force that the water exerts on the bottom of each reservoir. Explain your rankings.

FIGURE P13.23

24. **Water reservoir and faucet** The pressure at the top of the water in a city's gravity-fed reservoir is 1.0×10^5 N/m^2. Determine the pressure at the faucet of a home 42 m below the reservoir.
25. **Dutch boy saves Holland** An old story tells of a Dutch boy who used his fist to plug a 2.0-cm-diameter hole in a dike that was 3.0 m below sea level, thus preventing the flooding of part of Holland. What physical quantities can you determine from this information? Determine them.
26. BIO EST **Blood pressure** Estimate the pressure of the blood in your brain and in your feet when standing, relative to the average pressure of the blood in your heart of 1.3×10^4 N/m^2 above atmospheric pressure.
27. * BIO **Intravenous feeding** A glucose solution of density 1050 kg/m^3 is transferred from a collapsible bag through a tube and syringe into the vein of a person's arm. The blood pressure in the arm exceeds the atmospheric pressure by 1400 N/m^2. How high above the arm must the top of the liquid in the bottle be so that the pressure in the glucose solution at the needle exceeds the pressure of the blood in the arm?
28. * **Mountain climbing** Determine the change in air pressure as you climb from elevation of 1650 m at the timberline of Mount Rainier to its 4392-m summit, assuming an average air density of 0.82 kg/m^3. Will the real change be more or less than the one you calculated? Explain.
29. BIO EST **Giraffe raises head** Estimate the pressure change of the blood in the brain of a giraffe when it lifts its head from the grass to eat a leaf on an overhead tree. Without special valves in its circulatory system, the giraffe could easily faint when lifting its head.
30. * A truck transporting chemicals has crashed, and some dangerous liquid has spilled onto the ground and possibly entered a water well. An inspector fixes a pressure sensor to the end of a long string and lets the sensor slowly descend from the top of the well to the bottom. Using this device, he obtains the graph in Figure P13.30 that shows how the pressure P in the well changes with distance d measured from the top of the well. (a) Explain what features of the graph support the idea that there is another liquid in the well in addition to water. (b) Determine the density of the unknown liquid. Is the liquid above the water or below the water? (c) Determine the depth of the water, the depth of the unknown liquid, and the depth of the well.

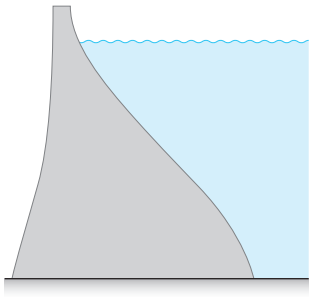


FIGURE P13.30

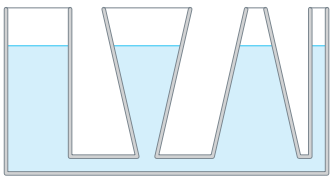
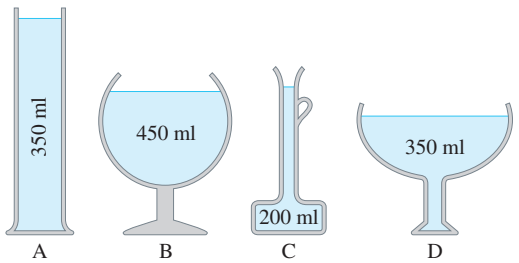
31. **Drinking through a straw** You are drinking water through a straw in an open glass. Select a small volume of water in the straw as a system and draw a force diagram for the water inside this volume that explains why the water goes up the straw.
32. * **More straw drinking** While you are drinking through the straw, the pressure in your mouth is 30 mm Hg below atmospheric pressure. What is the maximum length of a straw in an open glass that you can use to drink a fruit drink of density 1200 kg/m^3?
33. * Your office has a 0.020 m^3 cylindrical container of drinking water. The radius of the container is about 14 cm. When the container is full, what is the gauge pressure that the water exerts on the sides of the container halfway down from the top? All the way down?
34. * BIO EST **Eardrum** Estimate the net force on your 0.5-cm^2 eardrum that air exerts on the inside and the outside after you drive from Denver, Colorado (elevation 1609 m) to the top of Pikes Peak (elevation 4301 m). Assume that the air pressure inside and out are balanced when you leave Denver and that the average density of the air is 0.80 kg/m^3. What other assumptions did you make?
35. BIO **Eardrum again** You now go snorkeling. What is the net force exerted on your eardrum when you are 2.4 m under the water, assuming the pressure was equalized before the dive?



36. Water and oil are poured into opposite sides of an open U-shaped tube. The oil and water meet at the exact center of the U at the bottom of the tube. If the column of oil of density 900 kg/m^3 is 16 cm high on one side, how high is the water on the other side?
37. * Examine the vertical cross section of the Hoover Dam shown in **Figure P13.37**. Explain why the dam is thicker at the bottom than at the top.

FIGURE P13.37



38. * A test tube of length L and cross-sectional area A is submerged in water with the open end down so that the edge of the tube is a distance h below the surface. The water goes up into the tube so its height inside the tube is l. Describe how you can use this information to decide whether the air that was initially in the tube obeys the mathematical description for an isothermal process (Boyle's law). List your assumptions.
39. Half of a 20-cm-tall beaker is filled with glycerol (density 1259 kg/m^3) and the other half with olive oil (density 800 kg/m^3). (a) Draw a graph that shows how the density of the liquids in the beaker changes with the distance from the surface to the bottom of beaker. (b) Draw a graph that shows how the pressure in the liquids changes with the distance from the surface to the bottom of the beaker.
40. Blaise Pascal found a seemingly paradoxical situation when he poured water into the apparatus shown in **Figure P13.40**. The water level was the same in all four parts of the apparatus despite differences in the shapes of the parts and the masses of water in each part. Explain qualitatively the outcome of Pascal's experiment.

FIGURE P13.40

41. Four containers are filled with different volumes of water as shown in **Figure P13.41**. Rank the containers in order of decreasing pressure that the water exerts on the bottom of the containers.

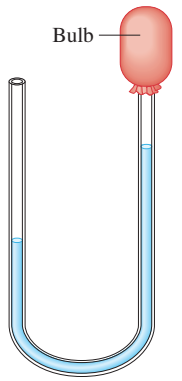
FIGURE P13.41

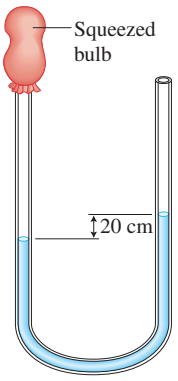
42. **Venus pressure and underwater pressure** Atmospheric pressure on Venus is 9.0×10^6 N/m^2. How deep underwater on Earth would you have to go to feel the same pressure?

13.4 Measuring atmospheric pressure

43. The reading of a barometer in your room is 780 mm Hg. What does this mean? What is the pressure in pascals?
44. How long would Torricelli's barometer have had to be if he had used oil of density 950 kg/m^3 instead of mercury?
45. Sometimes gas pressure is measured with a device called a *liquid manometer* (**Figure P13.45**). Explain how this instrument can be used to measure the pressure of gas in a bulb attached to one of the tubes.

FIGURE P13.45





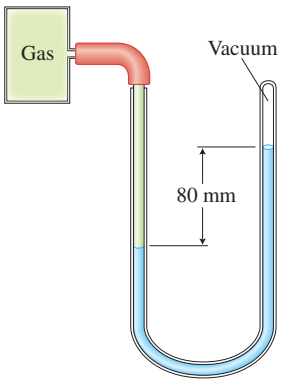


FIGURE P13.46

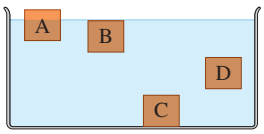
46. You use a liquid manometer with water to measure the pressure inside a rubber bulb. Before you squeeze the bulb, the water is at the same level in both legs of the tube. After you squeeze the bulb, the water in the opposite leg rises 20 cm with respect to the leg connected to the bulb (**Figure P13.46**). What is the pressure in the bulb? What assumptions did you make? How will the answer change if the assumptions are not valid?
47. * In a mercury-filled manometer (**Figure P13.47**), the open end is inserted into a container of gas and the closed end of the tube is evacuated. The difference in the height of the mercury is 80 mm. The radius of the connecting tube is 0.50 cm. (a) Determine the pressure inside the container in newtons per square meter. (b) An identical manometer has a connecting tube that is twice as wide. If the difference in the height of the mercury is the same, then what is the pressure in the container?

FIGURE P13.47



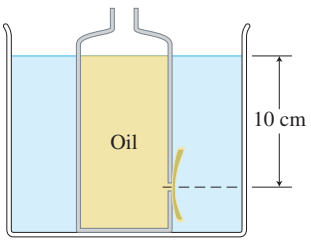
48. Examine the reading of the manometer that you use to measure the pressure inside car tires. What are the units? Does the manometer measure the absolute pressure of the air inside the tires or gauge pressure? How do you know?

13.5 Buoyant force

49. Draw a force diagram for an object that is floating at the surface of a liquid. Is the force exerted by air on the object included in your diagram? Explain.
50. Draw a cubic object that is completely submerged in a fluid but not resting on the bottom of the container. Then draw arrows to represent the forces exerted by the fluid on the top, sides, and bottom of the object. Make the arrows the correct relative lengths. What is the direction of the total force exerted by the fluid on the object?
51. Three people are holding three identical sealed metal containers, ready to release them. Container A is filled with air at atmospheric pressure and room temperature, container B is filled with helium at atmospheric pressure and room temperature, and container C is evacuated (all air has been pumped out). Draw force diagrams for the containers after they are released.
52. * Four cubes of the same volume are made of different materials: lead (density 11,300 kg/m^3), aluminum (density 2700 kg/m^3), wood (density 800 kg/m^3), and Styrofoam (density 50 kg/m^3). You place the cubes in a large container filled with water. Rank the buoyant forces that the water exerts on the cubes from largest to smallest.
53. * You place four identical cubes made of oak (density 900 kg/m^3) in water, olive oil (density 880 kg/m^3), alcohol (density 790 kg/m^3), and mercury (density 13,600 kg/m^3). Rank the buoyant forces that the liquids exert on the cubes from largest to smallest.

54. ** You fill a 20-cm-tall container with glycerol so that the glycerol (density 1260 kg/m^3) reaches the 10-cm mark. You place an oak cube (density 900 kg/m^3) into the container. Each side of the cube is 10 cm. (a) What is the distance x from the upper face of the cube to the glycerol surface assuming the cube is in an upright position? (b) Make a prediction using qualitative reasoning (without mathematics) about what will happen to the cube in (a) if you now add olive oil (density 800 kg/m^3) to the container until it is completely full. Will the distance x decrease, increase, or stay the same? (c) Determine the new distance x using mathematics (physics laws) and compare your result with the prediction in (b).
55. * A 30-g ball with volume 37.5 cm^3 is attached to the bottom of a glass beaker with a light string. When the beaker is filled with water, the ball floats fully submerged under the water surface. Draw a force diagram for the ball and determine the force exerted on the ball by the string.
56. ** You have a ball (volume V, average density ρ_B) and a glass beaker. The ball is attached to the bottom of the beaker with a light spring (coefficient k). When you fill the beaker with a liquid of density ρ_L, the ball floats fully submerged under the surface with the spring extended by x. Draw a force diagram for the ball and derive the expression for x in terms V, ρ_B, ρ_L, and k. Evaluate the expression using unit analysis and limiting case analysis.
57. * This textbook says that the upward force that a fluid exerts on a submerged object is equal in magnitude to the product of the density of the fluid, the gravitational constant g, and the volume of the submerged part of the object. Where did this equation come from?
58. * **Design** This textbook says that the upward force that a fluid exerts on a submerged object is equal in magnitude to the product of the density of the fluid, the gravitational constant g, and the volume of the submerged part of the object. Design an experiment to test this expression, including a prediction about the outcome of the experiment.
59. * You have four objects at rest, each of the same volume. Object A is partially submerged, and objects B, C, and D are totally submerged in the same container of liquid, as shown in **Figure P13.59**. Draw a force diagram for each object. Rank the densities of the objects from least to greatest and indicate whether any objects have the same density.

FIGURE P13.59



60. * **Does air affect what a scale reads?** A 60-kg woman with a density of 980 kg/m^3 stands on a bathroom scale. Determine the reduction of the scale reading due to air.
61. * When analyzing a sample of ore, a geologist finds that it weighs 2.00 N in air and 1.13 N when immersed in water. What is the density of the ore? What assumptions did you make to answer the question? If the assumptions are not correct, how would the answer be different?
62. * A pin through a hole in the middle supports a meter stick. Two identical blocks hang from strings at an equal distance from the center so the stick is balanced. What happens to the stick if one block is submerged in water of density 1000 kg/m^3 and the other block in kerosene of density 850 kg/m^3?
63. * A meter stick is supported by a pin through a hole in the middle. (a) Two blocks made of the same material but different sizes hang from strings at different positions in such a way that the stick balances. What happens when the blocks hang entirely submerged in beakers of water? (b) Next you hang two blocks of different masses but the same volume at different positions so the stick balances. What happens when these blocks hang completely submerged in beakers of water? Support your answer for each part using force diagrams with arrows drawn with the correct relative lengths.

13.6 Skills for analyzing static fluid problems

64. **Goose on a lake** A 3.6-kg goose floats on a lake with 40% of its body below the 1000-kg/m^3 water level. Determine the average density of the goose.
65. ** **Floating in seawater** A person of average density ρ_1 floats in seawater of density ρ_2. What fraction of the person's body is submerged? Explain.
66. * **Floating in seawater** A person of average density 980 kg/m^3 floats in seawater of density 1025 kg/m^3. What can you determine using this information? Determine it.
67. ** (a) Determine the force that a vertical string exerts on a 0.80-kg rock of density 3300 kg/m^3 when it is fully submerged in water of density 1000 kg/m^3. (b) If the force exerted by the string supporting the rock increases by 12% when the rock is submerged in a different fluid, what is that fluid's density? (c) If the density of another rock of the same volume is 12% greater, what happens to the buoyant force the water exerts on it?
68. * **Snorkeling** A 60-kg snorkeler (including snorkel, mask, and other gear) displaces 0.058 m^3 of water when 1.2 m under the surface. Determine the magnitude of the buoyant force exerted by the 1025-kg/m^3 seawater on the person. Will the person sink or drift upward?
69. * A helium balloon of volume 0.12 m^3 has a total mass (the helium plus the balloon) of 0.12 kg. Determine the buoyant force exerted on the balloon by the air if the air has density 1.13 kg/m^3. Determine the initial acceleration of the balloon when released.
70. * BIO **Protein sinks in water** A protein molecule of mass 1.1×10^{-22} kg and density 1.3×10^3 kg/m^3 is placed in a vertical tube of water of density 1000 kg/m^3. (a) Draw a motion diagram and a force diagram at the moment immediately after the molecule is released. (b) Determine the initial acceleration of the protein.
71. * How can you determine if a steel ball of known radius is hollow? List the equipment that you will need for the experiment, and describe the procedure and calculations. Can you determine how big the hollow part is if present in the ball?
72. ** **Crown composition** A crown is made of gold and silver. The scale reads its mass as 3.0 kg when in air and 2.75 kg when in water. Determine the masses of the gold and the silver in the crown. The density of gold is 19,300 kg/m^3 and that of silver is 10,500 kg/m^3.
73. * You place an open bottle filled with olive oil (density 880 kg/m^3) in a container filled with water so that the surfaces of both liquids are at the same level. The bottle has a hole in it 10 cm below the surface that is initially closed with adhesive tape (**Figure P13.73**). (a) Using Pascal's laws, predict what will happen when you remove the tape. Indicate any assumptions that you made. (b) Draw pressure-versus-depth graphs (similar to the graphs in Conceptual Exercise 13.3) for the states before and after you remove the tape. (c) If you predict any changes, determine their numerical values.

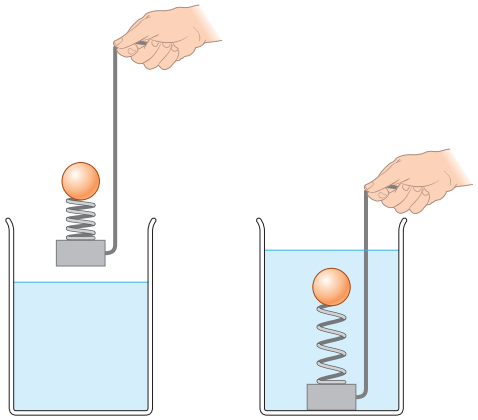


FIGURE P13.73

74. * You hold a ping-pong ball fully underwater (the initial state). When you release the ball, it jumps out of the water to a certain height above the surface. Let the final state be when the ball is just above the water surface, moving upward. Represent the process with energy bar charts (a) choosing the water, the ball, and Earth as the system, and (b) choosing the ball and Earth as the system. Indicate any assumptions that you made.
75. * You hang a steel ball on a string above a beaker that is filled to the top with water (the initial state). The beaker is sitting on a large empty tray. You slowly lower the ball until it reaches the bottom of the beaker. Some water spills over the rim of the beaker to the tray (the final state). (a) Represent the process with an energy bar chart choosing the water, the ball, and Earth as the system. (b) Repeat the analysis for a similar process with the same ball and the same amount of water, but a beaker tall enough so that no water spills over into the tray. Indicate any assumptions that you made.

76. * One end of a light spring is attached to a ping-pong ball, the other end to a heavy metal block that is fixed to a thin-wire holder (see **Figure P13.76**). You hold this setup so that the metal block is above the surface of water in a beaker (the initial state). You then slowly lower the setup until the metal block touches the bottom of the beaker (the final state). Represent the process with an energy bar chart, choosing the water, the ball, the spring, the block, and Earth as the system. Assume that the mass of the ball and the mass of the spring are much smaller than the mass of the block and so can be ignored. Indicate any other assumptions that you made.

FIGURE P13.76

77. * **Wood raft** Logs of density 600 kg/m^3 are used to build a raft. What is the maximum mass of the load that can be supported by a raft built from 300 kg of logs?
78. * EST **Standing on a log** A floating log is L long and d in diameter. What is the mass of a person who can stand on the log without getting her feet wet?
79. * **Ferryboat** A ferryboat is 12 m long and 8 m wide. Two cars, each of mass 1600 kg, ride on the boat for transport across the lake. How much farther does the boat sink into the water?
80. EST **Iceberg** Icebergs are large pieces of freshwater ice. Estimate the percentage of the volume of an iceberg that is underwater. Indicate any assumptions that you made.
81. * **Life preserver** A life preserver is manufactured to support a 70-kg person with 20% of his volume out of the water. If the density of the life preserver is 100 kg/m^3 and it is completely submerged, what must its volume be? List your assumptions.
82. ** To increase the effect of the buoyant force on a submarine, the crew replaces seawater in the ballast tanks with air. To push the seawater out of the tanks, they use compressed air from air flasks. The submarine is located 10 m below the surface in seawater with density 1030 kg/m^3 and temperature 6 °C. How many kilograms of air should the crew let out from the flasks to increase the difference between the gravitational force and the buoyant force exerted on the submarine by 5×10^6 N? Assume the temperature of air in the flasks is the same as the seawater temperature.

General Problems

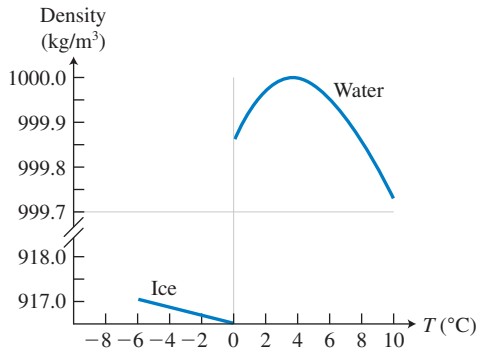
83. * Compare the density of water at 0 °C to the density of ice at 0 °C. Suggest possible explanations in terms of the molecular arrangements inside the liquid and solid forms of water that would account for the difference. If necessary, use extra resources to help answer the question.
84. * **Collapsing star** The radius of a collapsing star destined to become a pulsar decreases by 10% while at the same time 12% of its mass escapes. Determine the percent change in its density.
85. * **Deep dive** The *Trieste* research submarine traveled 10.9 km below the ocean surface while exploring the Mariana Trench in the South Pacific, the deepest place in the ocean. Determine the force needed to prevent a 0.10-m-diameter window on the side of the submarine from imploding. Assume that the pressure inside the submarine is 1 atm and the density of the water is 1025 kg/m^3.
86. * EST **Bursting a wine barrel** Pascal placed a long 0.20-cm-radius tube in a wine barrel of radius 0.24 m. He sealed the barrel where the tube entered it. When he added wine of density 1050 kg/m^3 to the tube so the column of wine was 8.0 m high, the cover of the barrel burst off the top of the barrel. Estimate the net force that caused the cover to come off.
87. * BIO **Lowest pressure in lungs** Experimentally determine the maximum distance you can suck water up a straw. Use this number to determine the pressure in your lungs above or below atmospheric pressure while you are sucking. Be sure to indicate any assumptions you made and show clearly how you reached your conclusion.
88. ** **Measuring ocean depth with a soda bottle** You can use an empty soda bottle with a cap to measure the depth to which you dive in the ocean. Dive to a certain depth, turn the closed bottle upside down (with the cap toward the sea bottom), and open the cap. A certain volume of seawater will enter the bottle, compressing the air that was trapped in it. Keep the bottle in an upside-down position and carefully close the bottle. Then swim up to the surface and measure the volume V_{water} of water in the bottle and the total volume V_0 of the bottle. (a) Derive the expression for the depth to which you dived in terms of V_{water}, V_0, and other relevant parameters. Indicate any assumptions that you made. Evaluate the expression using unit analysis and limiting case analysis.
89. * Justin is observing pearl-like strings of bubbles that move upward in his father's glass of champagne. He notices that as the bubbles rise, their volume increases (see **Figure P13.89**). He proposes the following explanation: "The pressure inside the bubble is equal to the pressure in the liquid surrounding the bubble. Because the pressure in the liquid decreases toward the surface of the liquid, the pressure in the ascending bubble decreases and therefore the volume of the bubble increases." Justin estimates that the size of a bubble near the surface is approximately twice that of a bubble 10 cm below the surface. Can Justin reject his explanation based on these data? Explain. If you answered yes, propose a different explanation that is consistent with the data and describe how you could test it. (Hint: Champagne contains dissolved carbon dioxide.)

FIGURE P13.89

90. ** You have an empty water bottle. Predict how much mass you need to add to it to make it float half-submerged. Then add the calculated mass and explain any discrepancy that you found. How did you make your prediction?
91. ** BIO **Flexible bladder helps fish sink or rise** A 1.0-kg fish of density 1025 kg/m^3 is in water of the same density. The fish's bladder contains 10 cm^3 of air. The bladder compresses to 4 cm^3. Now what is the density of the fish? Will it sink or rise? Explain.
92. * **Plane lands on Nimitz aircraft carrier** When a 27,000-kg fighter airplane lands on the deck of the aircraft carrier Nimitz, the carrier sinks 0.25 cm deeper into the water. Determine the cross-sectional area of the carrier.
93. Derive an equation for determining the unknown density of a liquid by measuring the magnitude of a force $T_{\text{S on O}}$ that a string needs to exert on a hanging object of unknown mass m and density ρ to support it when the object is submerged in the liquid.

Reading Passage Problems

BIO Free diving So-called "no-limits" free divers slide to deep water on a weighted sled that moves from a boat down a vinyl-coated steel cable to the bottom of a dive site. The diver reaches depths where a soda can would implode. After reaching the target depth, the diver releases the sled and an air bag opens and brings the diver quickly back to the surface. The divers have no external oxygen supply—just lungs full of air at the start of the dive. In August 2002, Tanya Streeter of the Cayman Islands held the women's no-limits free dive record at 160 m. In 2005 Patrick Musimu set the men's record with a 209.6-m free dive in the Red Sea just off the Egyptian coast (the record was later broken by Herbert Nitsch of Austria).



Musimu's 2005 dive took 3 minutes 28 seconds. He began the dive with his 9-L lungs full of air. By the time he passed the 200-m mark, Musimu's lungs had contracted to the size of a tennis ball. His body transferred blood from his limbs to essential organs such as the heart, lungs, and brain. This "blood shift" occurs when mammals submerge in water. Blood plasma fills the chest cavity, especially the lungs. Without this adaptation, the lungs would shrink and press against the chest walls, causing permanent damage. When he reached his target, Musimu released the weighted segment of the specialized sled that had taken him down and opened an airbag, which began his return to the surface at an average speed of 3–4 m/s.

94. Assuming Musimu weighs 670 N (150 lb) and is 1.6 m tall, 0.30 m wide, and 0.15 m thick, which answer below is closest to the magnitude of the force that the deep water exerted on one side of his body?
    (a) 0 (b) 670 N (130 lb)
    (c) 15,000 N (3000 lb) (d) 10^5 N (20,000 lb)
    (e) 10^6 N (200,000 lb)
95. Musimu's training allows him to hold up to 9 L = 9000 cm^3 of air when in a 1 atm environment. Which answer below is closest to the volume of that air if at pressure 22 atm?
    (a) 100 cm^3 (b) 200 cm^3 (c) 400 cm^3
    (d) 9000 cm^3 (e) 2×10^5 cm^3
96. As Musimu descends, the buoyant force that the water exerts on him
    (a) remains approximately constant.
    (b) increases a lot because the pressure is so much greater.
    (c) decreases significantly because his body is being compressed and made much smaller.
    (d) is zero for the entire dive.
    (e) There is not enough information to answer the question.
97. Why don't his lungs, heart, and chest completely collapse?
    (a) The return balloon helps counteract the external pressure.
    (b) There is no external force pushing directly on the organs.
    (c) The sled that helps him descend protects the front of his body.
    (d) Blood plasma moves from his extremities to his chest and the organs in it.
    (e) The air originally in the lungs is transferred to the vital organs.

Lakes freeze from top down We all know that ice cubes float in a glass of water. Why? Virtually every substance contracts when it solidifies—the solid is denser than the liquid. If this happened to water, ice cubes would sink to the bottom of a glass, and ice sheets would sink to the bottom of a lake. Fortunately, this doesn't happen. Liquid water expands by 9% when it freezes into solid ice at 0 °C, from a liquid density of a little less than 1000 kg/m^3 to a solid density of 917 kg/m^3.

But this is not the only special thing about water. While the density of most substances increases when they are cooled, water density shows a very peculiar temperature dependence (see **Figure 13.17**). As the temperature decreases, water density increases, but only until 4 °C, when water density reaches its maximum value, 1000.0 kg/m^3. As the temperature decreases further, water density decreases until at 0 °C water freezes and density abruptly decreases to 917 kg/m^3.

FIGURE 13.17

It is this peculiar water-density-temperature dependence that plays a vital role in the survival of animals and plants that live in water. In the winter when the water in a lake freezes, the solid ice stays at the top, forming an ice sheet. Water just below the ice sheet cools, but when it reaches 4 °C it becomes the most dense and sinks to the bottom of the lake. Since water colder than 4 °C is less dense, it stays above, keeping the bottom of the lake at a constant 4 °C. Note that if water were most dense at the freezing point, then in the winter the very cold water at the surface of lakes would sink. In this case the lake would freeze from the bottom up, and all life in it would be destroyed.

The expansion of water when it freezes has another important environmental benefit: the so-called freeze-thaw effect on sedimentary rocks. Water is absorbed into cracks in these rocks and then freezes in cold weather. The solid ice expands and cracks the rock, like a wood-cutter splitting logs. This continual process of liquid water absorption, freezing, and cracking releases mineral and nitrogen deposits into the soil and can eventually break the rock down into soil.

98. When is water densest?
    (a) When liquid at 0 °C
    (b) When solid ice at 0 °C
    (c) When liquid at 4 °C
    (d) Water density is always 1000.0 kg/m^3.
99. Why does water freeze from the top down?
    (a) The denser water at 0 °C sinks to the bottom of the lake.
    (b) The less dense ice at 0 °C rises above the liquid water at 0 °C.
    (c) The denser water at 4 °C sinks to the bottom of the lake.
    (d) Because of both a and b
    (e) Because of both b and c
100. Using Newton's second law, expressions for buoyant force and other forces, and the densities of liquid and solid water at 0 °C, find the fraction of an iceberg or an ice cube that is under liquid water.
    (a) 0.84 (b) 0.88 (c) 0.92
    (d) 0.96 (e) 1.00
101. A swimming pool at 0 °C has a very large chunk of ice floating in it—like an iceberg in the ocean. When the ice melts, what happens to the level of the water at the edge of the pool?
    (a) It rises. (b) It stays the same.
    (c) It drops. (d) It depends on the size of the chunk.
102. Which of the following is/are benefits of the temperature dependence of the density of water?
    (a) Fish and plants can survive winters without being frozen.
    (b) Over time, soil is formed from sedimentary rocks.
    (c) Water pipes when frozen in the winter do not burst.
    (d) Two of the above three
    (e) All of the first three

14

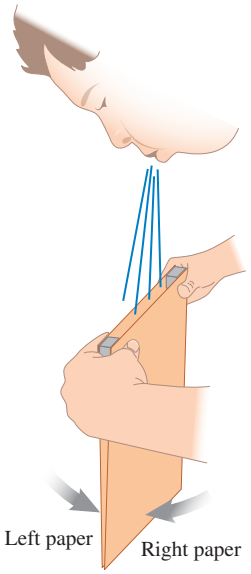
Fluids in Motion

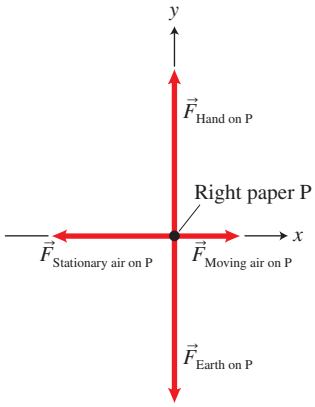
Plaque (fatty deposits) accumulates on the walls of arteries as cholesterol-laden blood flows by. As plaque grows, blood flows past at higher speed. If the blood is moving fast enough, it can dislodge deposits, which may then become lodged downstream and stop blood flow. If this stoppage occurs in the heart, it can cause a heart attack. In this chapter, we will learn why blood flows faster through an artery clogged with plaque and why the fast-moving stream of blood tends to pull the plaque off the artery wall.

- **How does blood flow dislodge plaque from an artery?**
- **Why can a strong wind cause the roof to blow off a house?**
- **Why do people snore?**

IN THE PREVIOUS CHAPTER, we investigated the behavior of static fluids. What happens when a gas or liquid moves across a surface—for example, when air moves across the roof of a house or when blood moves through a blood vessel? In this chapter, we will investigate and explain phenomena involving moving fluids—*fluid dynamics*.

BE SURE YOU KNOW HOW TO:





- Draw work-energy bar charts (Section 7.2).
- Apply the concept of pressure to explain the behavior of liquids (Section 13.2).
- Draw force diagrams and apply Newton's second law (Section 3.5).

14.1 Fluids moving across surfaces—qualitative analysis

You learned in Chapters 12 and 13 that a key property of a static fluid is its pressure. What happens to that pressure when a fluid moves? To investigate this, we will analyze the simple experiment described in Observational Experiment Table 14.1.

OBSERVATIONAL EXPERIMENT TABLE 14.1 Pressure inside a moving fluid

VIDEO OET 14.1

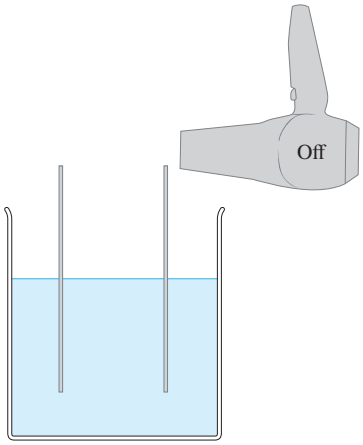
Observational experiment	Analysis
Hold two pieces of paper separated by plastic blocks and blow down directly between them. You see the pieces of paper coming close together, as if they are pushed toward the moving air. 	We consider the piece of paper on the right to be our system and examine the moment when the paper starts moving to the left. We draw forces exerted on the paper in the horizontal direction. For the system to start moving, the sum of the horizontal forces must point to the left—from the region of stationary air to the region of moving air. 

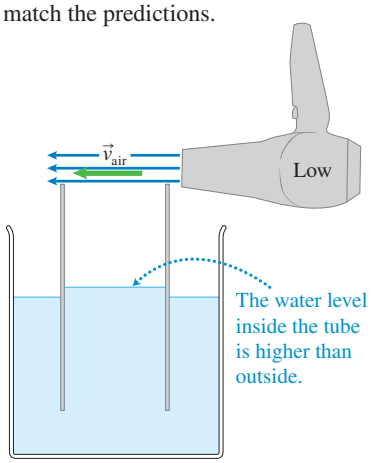
Pattern

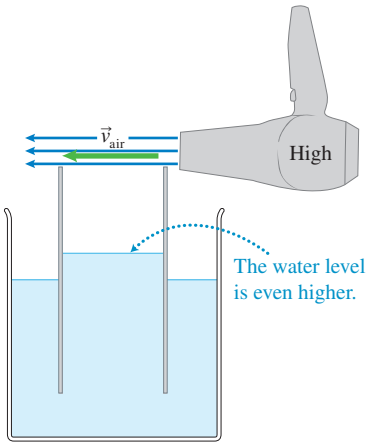
Based on the analysis of the experiment and using the force diagram, we can infer that air moving along the surface of an object exerts a smaller force on the object. Given that force divided by the area over which it is exerted is pressure, we conclude that the air moving along a surface exerts less pressure on the object than stationary air.

Bernoulli's effect

Extrapolating from the pattern in Table 14.1, could it be that for any fluid, the speed with which fluid is moving along the object and the pressure exerted by this fluid on the object are related: the greater the speed, the smaller the pressure? Let's test this hypothesis experimentally.







It is important to note here that in all of the experiments, the movement of the fluid was parallel to the surface of interest. When the fluid is moving perpendicular to the surface of interest, it exerts a force in the direction of motion (you can think of the momentum of fluid particles changing as the particles hit the surface). You can clearly observe this effect if you repeat the experiment in Testing Experiment Table 14.2 with the hairdryer blowing directly downward into the tube—the water level inside the tube lowers.

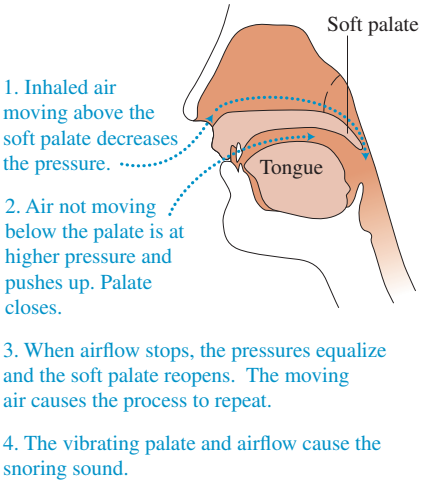
TESTING
EXPERIMENT TABLE 14.2

How are the speed of a fluid and its pressure related?

VIDEO
TET 14.2

Testing experiment	Prediction	Outcome
We cut the top and bottom off a plastic bottle to make a plastic tube and put it into a container of water. The level of the water in the tube is the same as in the container. Then using a hair dryer set to cold, we blow cold air parallel to the surface of the water right above the tube, first using a low-speed setting and then a high-speed setting. 	If a faster-moving fluid exerts less pressure than a stationary fluid, and we blow air parallel to the opening of the tube, then the pressure at the top of the tube (but also inside the tube) should be lower than atmospheric pressure. When the speed of the moving air increases, the pressure should decrease. The pressure outside the tube, above the surface of the water in the container is atmospheric; therefore, the sum of the forces on an element of water inside the tube should point upward and the water in the tube should rise until the sum of the forces exerted on the raised water inside the tube is zero. The height of the water inside the tube should increase when the hair dryer is switched to high.	The outcomes are shown in the figures. They match the predictions.  

Conclusion



The hypothesis that the pressure exerted by a faster-moving fluid along an object is less than the pressure exerted by a slower-moving fluid was not disproved.

It is important to note here that in all of the experiments, the movement of the fluid was parallel to the surface of interest. When the fluid is moving perpendicular to the surface of interest, it exerts a force in the direction of motion (you can think of the momentum of fluid particles changing as the particles hit the surface). You can clearly observe this effect if you repeat the experiment in Table 14.2 with the hairdryer blowing directly downward into the tube—the water level inside the tube lowers.

At this point, without evidence to the contrary, we can say that as a fluid's speed parallel to a surface increases, the pressure that the moving fluid exerts on the surface decreases. This statement is a qualitative version of a principle formulated in 1738 by Daniel Bernoulli and named in his honor.

Bernoulli's effect The pressure that a fluid exerts on a surface *decreases* as the speed with which the fluid moves parallel to the surface *increases*.

FIGURE 14.1 Snoring occurs when the soft palate opens and closes due to the starting and stopping of airflow across it.

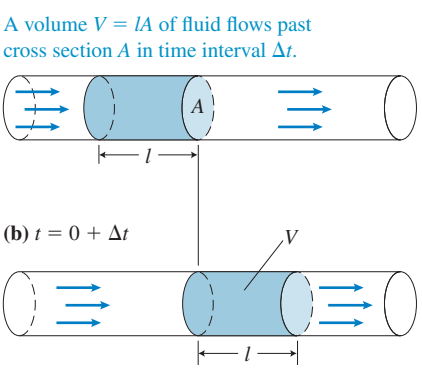
Bernoulli's effect has important fluid-flow implications in biological systems—for example, in the flow of blood through blood vessels. The blood pressure against the wall of a vessel depends on how fast the blood is moving—pressure is lower when the blood is moving faster. Let's look at another biological application of Bernoulli's effect.

Snoring

A snoring sound occurs when air moving through the narrow opening above the soft palate at the back of the roof of the mouth has lower pressure than nonmoving air below the palate (**Figure 14.1**). The normal air pressure below the soft palate, where the air is not moving, pushes the palate closed. When airflow stops, the pressures equalize and the passage reopens. The rhythmic opening and closing of the soft palate against the throat leads to the snoring sound.

REVIEW QUESTION 14.1 What is the empirical evidence for Bernoulli's effect?

14.2 Flow rate and fluid speed



We have found qualitatively that the pressure of a fluid along the direction of flow depends on the speed of the moving fluid—the greater the speed, the lower the pressure. In this section, we will learn new physical quantities that we will need to describe the effect quantitatively. The quantitative analysis is much easier if we limit our investigations to fluids in confined regions—pipes or tubes.

Perhaps you have taken a shower in which little water flowed from the showerhead. In physics, we would say the water flow rate was low. The **flow rate *Q*** is an important consideration in designing showerheads. A smaller flow rate will save water, but a larger flow rate will help you rinse off faster. Flow rate is defined as the volume V of fluid that moves through a cross section of a pipe divided by the time interval Δt during which it moved (see **Figure 14.2**):

$$Q = \frac{V}{\Delta t} \tag{14.1}$$

The SI unit of flow rate is m^3/s, but you may also see it as ft^3/s, ft^3/min, gallons/min, L/min, or any unit of volume divided by any unit of time interval. Notice that flow rate in m^3/s is different from the speed of the fluid v in m/s.

FIGURE 14.2 Flow rate is the volume of fluid that passes a cross section of a vessel in a given time interval.

TIP The symbols V, t, and Q are also used in other aspects of physics. For example, a lowercase v denotes speed, the capital letter T is used for temperature, and in future chapters we will use Q for two other unrelated quantities. Because these symbols are often used to indicate different quantities, it is important when working with equations to try to visualize their meaning with concrete images (for example, the volume of water flowing out of a faucet during 1 s).

How does the flow rate relate to the speed of the moving fluid? To explore the relationship, consider Figure 14.2a. Over a certain time interval Δt the shaded volume of fluid passes a cross section of area A at some position along the pipe. Thus, after a time Δt, the back part of this fluid volume has in effect moved forward to the position shown in Figure 14.2b. The volume V of fluid in the shaded portion of the cylinder is the product of its length l and the cross-sectional area A of the pipe:

$$V = lA$$

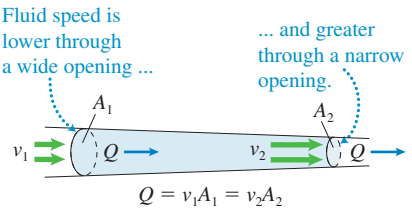
Thus, the fluid flow rate is

$$Q = \frac{V}{\Delta t} = \frac{lA}{\Delta t} = \left(\frac{l}{\Delta t}\right)A$$

However, l is also the distance the fluid moves in a time interval Δt. Thus, $l/\Delta t$ is the average fluid speed v. Substituting $v = l/\Delta t$ into the above equation, we find that

$$Q = vA \tag{14.2}$$

The flow rate is equivalent to the average fluid speed multiplied by the cross-sectional area of the pipe.



When an incompressible fluid (such as water) flows through a pipe with variable cross-sectional area (**Figure 14.3**), the amount of fluid entering at cross section A_1 must equal the amount of fluid leaving at cross section A_2. Thus the flow rate should remain constant. What must change is the speed of the fluid as it travels through the narrower part of the pipe. In the narrow section of the pipe (A_2), the speed will be greater in order to keep the flow rate constant. Thus, the flow rate past cross section A_1 equals that past cross section A_2:

$$Q_1 = v_1A_1 = v_2A_2 = Q_2 \tag{14.3}$$

where v_1 is the average speed of the fluid passing cross section A_1, and v_2 is the average speed of the fluid passing cross section A_2. Equation (14.3) is called the **continuity equation** and is used to relate the cross-sectional area and average speed of fluid flow in different parts of a rigid pipe carrying an incompressible fluid.

TIP The definition of flow rate is an operational definition, not a cause-effect relationship, because it is the speed of the fluid that depends on the flow rate and the cross-sectional area. The flow rate is determined by the source of the fluid (for example, how much you open the faucet).

FIGURE 14.3 The flow speed $v_2 > v_1$ depends on the cross-sectional area of pipe carrying the fluid.

QUANTITATIVE EXERCISE 14.1 **Speed of blood flow in the aorta**

The heart pumps blood at an average flow rate of 80 cm^3/s into the aorta, which has a diameter of 1.5 cm. Determine the average speed of blood flow in the aorta.

Represent mathematically The flow rate can be determined by rearranging Eq. (14.2):

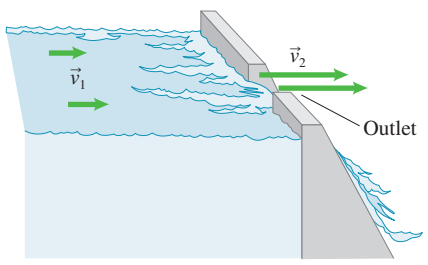
$$v = \frac{Q}{A}$$

where the cross-sectional area of the aorta is

$$A = \pi r^2 = \pi\left(\frac{d}{2}\right)^2$$

Solve and evaluate Combining the above two equations, we find that the average speed of blood flow in the aorta is

$$v = \frac{Q}{A} = \frac{Q}{\pi(d/2)^2} = \frac{(80\ \text{cm}^3/\text{s})}{\pi(1.5\ \text{cm}/2)^2} = 45\ \text{cm/s}$$



The unit is correct. The magnitude is reasonable—about half a meter each second.

Try it yourself Determine the average speed of blood flow if the diameter is reduced from 1.5 cm to 1.0 cm but the flow rate is the same.

Answer 100 cm/s

Notice that blood speed more than doubles when the aorta diameter decreases by 33%. Vessel diameter has a very significant effect on the flow rate of fluid through a vessel, including those in biological systems. The narrower the blood vessel, the faster the blood flows, increasing the risk of dislodging plaque. Likewise, the narrower the airway from the nose to the mouth, the faster the air moves and the more likely you are to snore. These effects depend on the speed of the fluid, like blood or air in different parts of a vessel or pipe in which the diameter changes from one section to another.

FIGURE 14.4 Why is $v_2 > v_1$?

REVIEW QUESTION 14.2 Why does water in a river flow more slowly just before a dam than it does while passing through the outlet of the dam (**Figure 14.4**)?

FIGURE 14.5 Laminar flow.

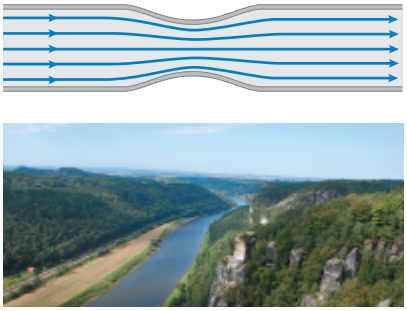


FIGURE 14.6 Turbulent flow.

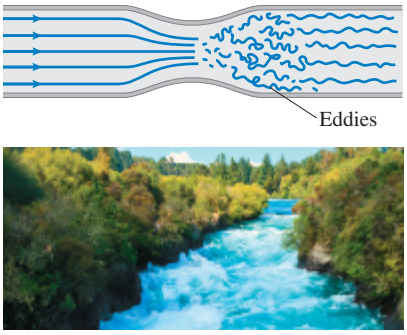

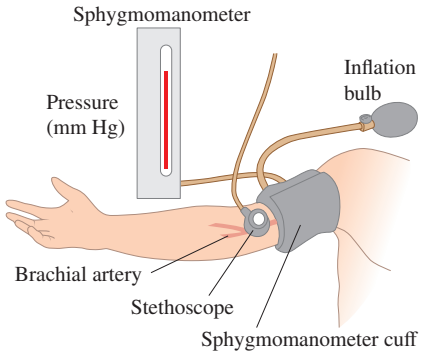

FIGURE 14.7 Streamlining a truck.

FIGURE 14.8 Measuring blood pressure

14.3 Types of fluid flow

Before we can proceed to describing Bernoulli's effect quantitatively, we need to learn more about fluid flow.

What kinds of flow can occur? There is the smooth flow that we see in a wide river and the whitewater flow that we see as water rushes and swirls through a narrow channel. Studies of fluid flow in wind tunnels indicate that there are two primary kinds of flow: laminar flow and turbulent flow. In **laminar flow**, every particle of fluid that passes a particular point follows the same path as the particles that preceded it. These paths are called **streamlines**. This is the smooth flow that we see in a wide river (see the fluid flowing smoothly in the wide tube in **Figure 14.5**). **Turbulent flow**, on the other hand, is characterized by agitated, disorderly motion. Instead of following a given path, the fluid forms whirlpool patterns called eddies, which come and go randomly, or sometimes become semi-stable (see **Figure 14.6**). Turbulent flow occurs when a fluid moves around objects and through pipes at high speed.

The force exerted by the fluid on objects is called the **drag force**. This is the force you "feel" when running against the wind. Due to the drag force, more kinetic energy is converted into thermal energy in turbulent flow than in laminar flow. Designing a car so that air moves over it with laminar flow reduces the drag force that the air exerts on the car and improves gasoline mileage. Placing a curved dome above the cab of a truck deflects air up and over the trailer, reducing turbulent flow and increasing gas mileage by more than 10% (see **Figure 14.7**).

Measuring blood pressure

To measure a person's blood pressure, a nurse uses a device called a *sphygmomanometer* (see **Figure 14.8**). The nurse places a cuff around the upper arm of a patient at about the level of the heart and places a stethoscope on the inside of the elbow above the brachial artery in the arm. The nurse then increases the gauge pressure in the cuff to about 180 mm Hg by pumping air into the cuff. The expanded cuff pushes on the brachial artery and stops blood flow in the arm. Then the nurse slowly releases the air from the cuff, decreasing the pressure of the air in it. When the pressure in the cuff is equal to the *systolic* pressure (120 mm Hg if the systolic blood pressure is normal), blood starts to squeeze through the artery past the cuff. The flow is intermittent and turbulent and causes a sound heard with the stethoscope. This turbulent sound continues until the cuff pressure decreases below the *diastolic* pressure (80 mm Hg for normal diastolic blood pressure). At that point the artery is continually open and blood flow is laminar and makes no sound. The systolic and diastolic pressure numbers together make up the blood pressure measurement.

REVIEW QUESTION 14.3 Is it easier for the heart to pump blood if the flow of the blood through the blood vessels is laminar or if it is turbulent? Explain.

14.4 Bernoulli's equation

Earlier in this chapter we investigated Bernoulli's effect qualitatively. In this section we will learn how to describe it quantitatively.

To achieve this goal, we use the case of a fluid flowing through a pipe, as shown in **Figure 14.9a**. We assume that (1) the fluid is incompressible, (2) there are no resistive forces exerted on the flowing fluid, and (3) the flow is laminar. We can apply the work-energy principle to describe the behavior of the fluid as it moves a short distance along the pipe. Consider the system to be composed of the shaded volume of fluid pictured in Figures 14.9a and b and Earth.

FIGURE 14.9 Applying the work-energy principle to fluid flow.

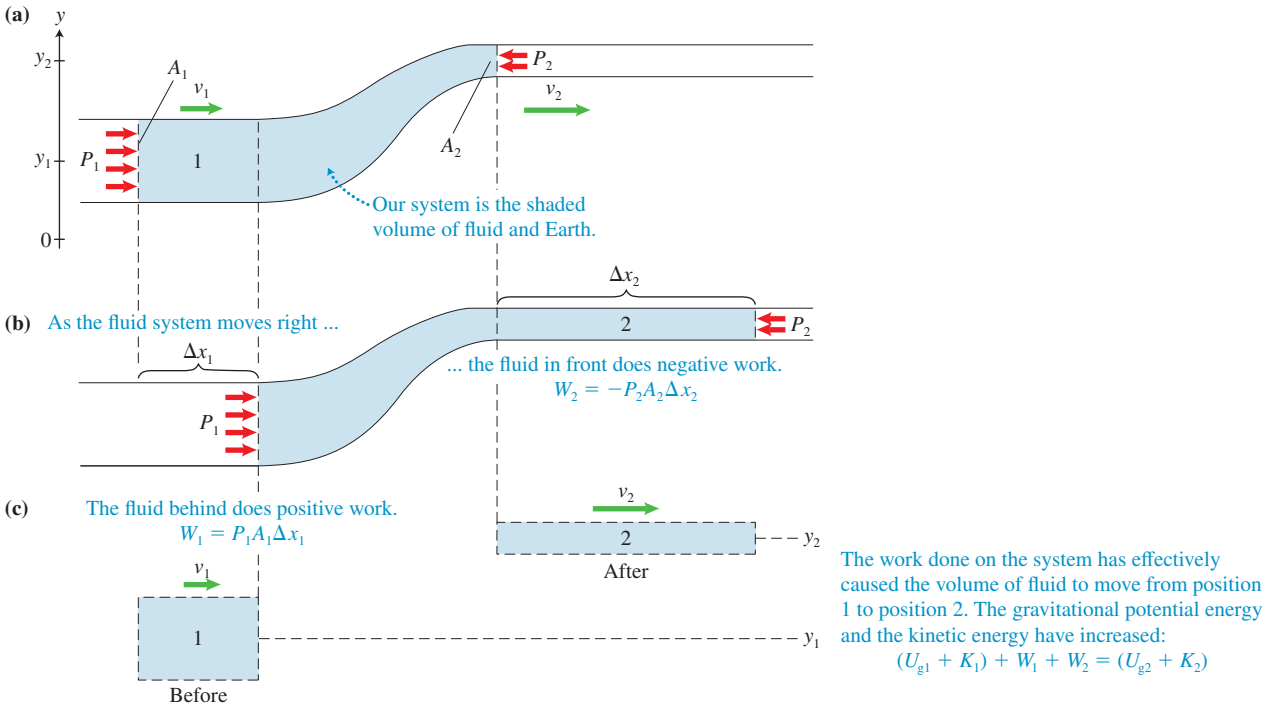

Figure 14.9a shows us the initial state of the system. As the volume of fluid flows to the right, the fluid behind it at position 1 exerts a force of magnitude $F_1 = P_1A_1$ to the right, where P_1 is the fluid pressure against the left side of the volume and A_1 is the cross-sectional area of the left side of the volume. Simultaneously, the fluid ahead of the system at position 2 exerts a force in the opposite direction of magnitude $F_2 = P_2A_2$, where P_2 is the fluid pressure against the right side of the volume and A_2 is the cross-sectional area of the right side of the volume.

In Figure 14.9b, the shaded volume of fluid has moved to the right. Because the pipe is narrower at 2, the right side of the fluid at position 2 moves a greater distance than the left side of the same volume of fluid in the wider part of the pipe at position 1. The net effect of the movement of the fluid a short distance to the right is summarized in Figure 14.9c. The volume of fluid initially at position 1 moving at speed v_1 has now been transferred, in effect, to position 2 where it moves at speed v_2. The volume of fluid stays constant, since we assume the fluid is incompressible. The fluid is now moving faster through the narrow tube at position 2 than it was earlier when moving through the wider tube at position 1, thus we have an increase in kinetic energy. The fluid at position 2 is at a higher elevation than when at position 1, thus the gravitational potential energy of the system increases. The energies changed as a result of the work done by the forces exerted by the fluid behind and ahead of the shaded volume. We can represent this quantitatively using the generalized work-energy equation [Eq. (7.3)].

$$(K_1 + U_{g1}) + W = (K_2 + U_{g2})$$

If we move the terms with the subscript 1 to the right side of the equation, we have

$$W = (K_2 - K_1) + (U_{g2} - U_{g1})$$

or

$$W = \Delta K + \Delta U_g \tag{14.4}$$

Let us now write expressions for each of the terms in the above equation.

Work done Two forces are doing work on the system. The fluid behind the system exerts a force F_1 to the right on the left side of the system over a distance Δx_1. The fluid ahead of the system exerts a force F_2 to the left on the right side of the system over a distance Δx_2. (Figures 14.9a and b show fluid pressures; the corresponding forces have

magnitudes $F_1 = P_1A_1$ and $F_2 = P_2A_2$.) The force F_1 does positive work since it points in the direction of the motion of the system. The force F_2 does negative work since it points in the direction opposite the motion of the system. The total work done on the system is

$$\begin{aligned} W &= F_1 \Delta x_1 \cos 0^\circ + F_2 \Delta x_2 \cos 180^\circ \\ &= P_1A_1 \Delta x_1 - P_2A_2 \Delta x_2 \end{aligned}$$

The volume of fluid V that has moved from the left to the right is $V = A_1 \Delta x_1 = A_2 \Delta x_2$ since the fluid is incompressible. The preceding expression for work becomes

$$W = P_1V - P_2V = (P_1 - P_2)V$$

Change in kinetic energy The mass m of the system (the moving volume of fluid) is related to its density ρ and volume V:

$$m = \rho V$$

As the system moves from the initial to the final state, the speed of the element of fluid that effectively moved changes from v_1 to v_2. Thus, the kinetic energy change of the mass m of fluid shown in Figure 14.9c is

$$\Delta K = \tfrac{1}{2}mv_2^2 - \tfrac{1}{2}mv_1^2 = \tfrac{1}{2}\rho V v_2^2 - \tfrac{1}{2}\rho V v_1^2$$

Change in gravitational potential energy The gravitational potential energy of the system has also changed because part of the system has moved from elevation y_1 to elevation y_2. The change in gravitational potential energy is then

$$\Delta U_g = mg(y_2 - y_1) = \rho V g(y_2 - y_1)$$

We can now substitute the above three expressions into Eq. (14.4) to get

$$(P_1 - P_2)V = (\tfrac{1}{2}\rho V v_2^2 - \tfrac{1}{2}\rho V v_1^2) + \rho V g(y_2 - y_1)$$

If the common V is canceled from each term, we find that

$$P_1 - P_2 = \tfrac{1}{2}\rho(v_2^2 - v_1^2) + \rho g(y_2 - y_1)$$

By dividing by V in that last step we have changed the units of each term in the equation from energy (measured in joules) to **energy density** (measured in joules per cubic meter). Energy density is the same as energy per unit volume of fluid and appears on the right side of the above equation. The left-hand side represents the amount of work done on the fluid per unit volume of fluid.

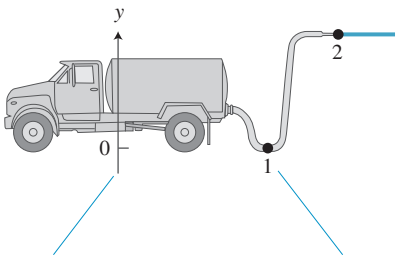
Bernoulli's equation relates the pressures, speeds, and elevations at two points on the same streamline in laminar flow in a fluid:

$$P_1 - P_2 = \tfrac{1}{2}\rho\,(v_2^2 - v_1^2) + \rho g(y_2 - y_1) \tag{14.5}$$

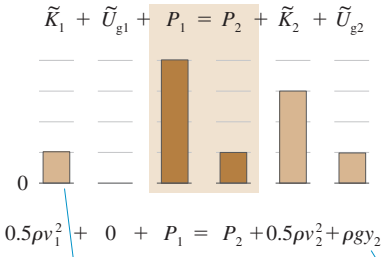
The equation can be rearranged into an alternate form:

$$\tfrac{1}{2}\rho v_1^2 + \rho g y_1 + P_1 = P_2 + \tfrac{1}{2}\rho v_2^2 + \rho g y_2 \tag{14.6}$$

The sum of the kinetic and gravitational potential energy densities and the pressure at position 1 equals the sum of the same three quantities at position 2.



It is important to remember the assumptions that we used to derive Bernoulli's equation. It describes quantitatively the flow of a frictionless, nonturbulent, incompressible fluid.



Using Bernoulli bar charts to understand fluid flow

Bernoulli's equation looks fairly complex and might be difficult to use for visualizing fluid dynamics processes. However, since Bernoulli's equation is based on the work-energy principle, we can represent such processes using energy bar charts similar to the ones used

in Chapters 7 and 13 (here the bars represent pressures and energy densities; we use a ~ over the energy symbols to emphasize that they are energy densities, not energies). Physics Tool Box 14.1 describes how to construct a fluid dynamics bar chart for the following process. A fire truck pumps water through a big hose up to a smaller hose on the ledge of a building. Water sprays out of the smaller hose onto a fire. Compare the pressure in the hose at the lowest point of the larger hose to the pressure at the exit of the smaller hose.

PHYSICS TOOL BOX 14.1 **Constructing a bar chart for a moving fluid**

1. Sketch the situation. Include an upward-pointing y-coordinate axis.
2. Choose points 1 and 2 at positions in the fluid that will help you achieve the goal of your analysis.
3. Construct a Bernoulli bar chart.
4. Use the bar chart and the sketch to help apply Bernoulli's equation.

To start, first draw a sketch of the process. Choose positions 1 and 2 at appropriate locations in order to help answer the question. One of the positions might be a place where you want to determine the pressure in the fluid and the other position a place where the pressure is known. For the water pump-hose process, it is useful to choose position 1 (the location of the unknown pressure) and position 2 at the exit of the water from the small hose (at known atmospheric pressure).

Represent this process by placing bars of appropriate relative lengths on the chart (the absolute lengths are not known). It is often easiest to start by analyzing the gravitational potential energy density. Use a vertical y-axis with a well-defined origin to keep track of the gravitational potential energy densities. For the fire hose process, choose position 1 as the origin of the vertical coordinate system. The gravitational potential energy density at position 1 is then zero. The exit of the water from the small hose is at higher elevation; thus, there is a positive gravitational potential energy density bar for position 2 (in the bar chart we arbitrarily assign it one positive unit of energy density).

Next, consider the kinetic energy. The water flows from a wider hose at position 1 to a narrower hose at position 2. Thus the kinetic energy density at 2 is greater than at 1—thus the longer bar at position 2. We arbitrarily assume that the kinetic energy density bar for position 1 is one unit and that for position 2 is three units.

Notice now that the total length of the bars on the right side of the chart is much higher than on the left side (the difference is three units). To account for the difference we need to consider the change in pressure. Since the fluid pressures at 1 and 2 are analogous to the work done on the system in an ordinary work-energy bar chart, P_1 and P_2 appear in the shaded box in the center of the bar chart, where work is represented. The difference in the pressure heights should account for the total difference in the energy densities. Thus, we draw the bar for P_1 three units higher than for P_2. The bar chart is now complete. We can use it to write a mathematical description for the process and solve for any unknown quantity.

REVIEW QUESTION 14.4 Compare and contrast work-energy bar charts and Bernoulli bar charts.

14.5 Skills for analyzing processes using Bernoulli's equation

In this section, we will adapt our problem-solving strategy to analyze processes involving moving fluids. In this case, we describe and illustrate a strategy for finding the speed of water as it leaves a bottle. The general strategy is on the left side of the table and the specific process is on the right.

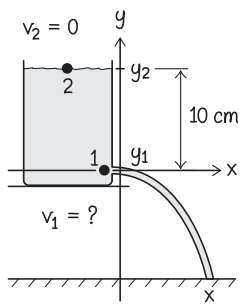
PROBLEM-SOLVING STRATEGY 14.1 Applying Bernoulli's equation

Sketch and translate

- Sketch the situation. Include an upward-pointing y-coordinate axis. Choose an origin and positive direction for the coordinate axis.
- Choose points 1 and 2 at positions in the fluid where you know the pressure/speed/position or that involve the quantity you are trying to determine.
- Choose a system.

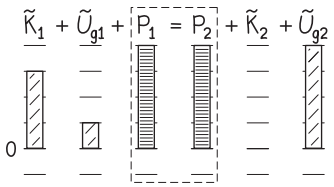
Simplify and diagram

- Identify any assumptions you are making. For example, can we assume that there are no resistive forces exerted on the flowing fluid?
- Construct a Bernoulli bar chart.



Represent mathematically

- Use the sketch and bar chart to help apply Bernoulli's equation.
- You may need to combine Bernoulli's equation with other equations, such as the equation of continuity $Q = v_1A_1 = v_2A_2$ and the definition of pressure $P = F/A$.



EXAMPLE 14.2 **Removing a tack from a water bottle**

What is the speed with which water flows from a hole punched in the side of an open plastic bottle? The hole is 10 cm below the water surface.

- Choose the origin of the vertical y-axis to be the location of the hole.
- Choose position 1 to be the place where the water leaves the hole and position 2 to be a place where the pressure, elevation, and water speed are known—at the water surface $y_2 = 0.10$ m. The pressure in Bernoulli's equation at both positions 1 and 2 is atmospheric pressure, since both positions are exposed to the atmosphere ($P_1 = P_2 = P_{atm}$).
- Choose Earth and the water as the system.

- Assume that no resistive forces are exerted on the flowing fluid.
- Assume that y_2 and y_1 stay constant during the process, since the elevation of the surface decreases slowly compared to the speed of the water as it leaves the tiny hole.

- Because the water at the surface is moving very slowly relative to the hole, assume that $v_2 = 0$.
- Draw a bar chart that represents the process.

- We see from the sketch and the bar chart that the speed of the fluid at position 2 is zero (zero kinetic energy density) and that the elevation is zero at position 1 (zero gravitational potential energy density). Also, the pressure is atmospheric at both 1 and 2. Thus

$$\tfrac{1}{2}\rho(0)^2 + \rho g y_2 + P_{atm} = P_{atm} + \tfrac{1}{2}\rho v_1^2 + \rho g(0)$$

$$\Rightarrow \rho g y_2 = \tfrac{1}{2}\rho v_1^2$$

Solve and evaluate

- Solve the equations for an unknown quantity.
- Evaluate the results to see if they are reasonable (the magnitude of the answer, its unit, how the answer changes in limiting cases, and so forth).

- Solve for v_1:

$$v_1 = \sqrt{2gy_2}$$

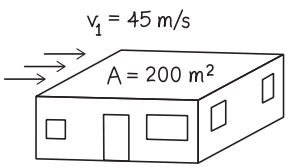
Substituting for g and y_2, we find that

$$v_1 = \sqrt{2(9.8\ \text{m/s}^2)(0.10\ \text{m})} = 1.4\ \text{m/s}$$

- The unit m/s is the correct unit for speed. The magnitude seems reasonable for water streaming from a bottle (if we obtained 120 m/s it would be unreasonably high).

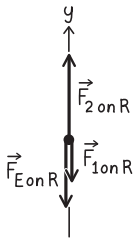
Try it yourself In the above situation the water streams out of the bottle onto the floor a certain horizontal distance away from the bottle. The floor is 1.0 m below the hole. Predict this horizontal distance using your knowledge of projectile motion. (Hint: Use Eqs. (4.7) and (4.8).)

Answer The equations yield a result of 0.63 m. However, if we were to actually perform this experiment with a tack-sized hole, the water would land short of our prediction because of resistive forces exerted by the hole on the water. In order to make the water land closer to 0.63 m from the bottle, we must increase the diameter of the hole. We discuss the effect of resistive forces on fluid flow later in the chapter.



Blowing the roof off a house

You've no doubt seen images of roofs being blown from houses during tornadoes or hurricanes. How does that happen? On a windy day, the air inside the house is not moving, whereas the air outside is moving very rapidly. The air pressure inside the house is therefore greater than the air pressure outside, creating a net pressure that pushes outward against the roof and windows. If the net pressure becomes great enough, the roof and/or the windows will blow outward off of the house. In the following example, we do a quantitative estimate of the net force exerted by the inside and outside air on a roof.



EXAMPLE 14.3 **Effect of high-speed air moving across the roof of a house**

During a storm, air moves at speed 45 m/s (100 mi/h) across the top of the 200-m^2 flat roof of a house. Estimate the net force exerted by the air pushing up on the inside of the roof and the outside air pushing down on the outside of the roof. Indicate any assumptions made in your estimate.

Sketch and translate The situation is shown at right. We need to determine the pressure just above and below the roof.

Simplify and diagram A force diagram for the roof is shown here. The air above the house exerts a downward force on the roof $F_{1\text{ on R}} = P_1A$, where P_1 is the air pressure above the house and A is the area of the roof. The air inside the house pushes up, exerting a force on the roof $F_{2\text{ on R}} = P_{\text{atm}}A$, where P_{atm} is the assumed atmospheric pressure of the stationary air inside the house. We assume that the air is incompressible and flows without friction or turbulence and that the roof is fairly thin so that the air has approximately the same gravitational potential energy density at points 1 and 2.

Represent mathematically With the y-axis oriented upward, the net force exerted by the air on the roof is

$$F_{\text{net Air}} = F_{2\text{ on R}} - F_{1\text{ on R}} = P_{\text{atm}}A - P_1A$$
$$= (P_{\text{atm}} - P_1)A$$

We use Bernoulli's equation to find this pressure difference.

$$P_2 + \tfrac{1}{2}\rho v_2^2 + \rho g y_2 = \tfrac{1}{2}\rho v_1^2 + \rho g y_1 + P_1$$
$$\Rightarrow P_{\text{atm}} + 0 + \rho g y_2 = \tfrac{1}{2}\rho v_1^2 + \rho g y_1 + P_1$$
$$\Rightarrow P_{\text{atm}} - P_1 = \tfrac{1}{2}\rho v_1^2 + (\rho g y_1 - \rho g y_2) = \tfrac{1}{2}\rho v_1^2 + 0$$

We can now determine the net force exerted by the air on the roof.

$$F_{\text{net Air}} = (P_{\text{atm}} - P_1)A = \tfrac{1}{2}\rho v_1^2 A$$

(CONTINUED)

Solve and evaluate

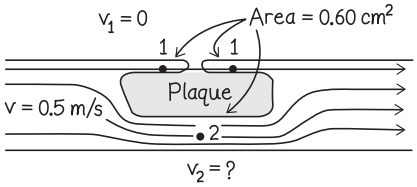
$$F_{\text{net Air}} = \tfrac{1}{2}\rho v_1^2 A$$
$$= \tfrac{1}{2}(1.3\ \text{kg/m}^3)(45\ \text{m/s})^2(200\ \text{m}^2) = 2.6 \times 10^5\ \text{N}$$

The result is an upward net force that is enough to lift more than ten cars of combined mass 27,000 kg.

We were a little lax in applying Bernoulli's equation in this example. The equation relates the properties of a fluid at two points along the same streamline. A streamline does not flow between just below the roof and just above the roof. We could, with some more complex reasoning, use the equation correctly by considering two streamlines that start far from the house at the same pressure. One ends up in the house under its roof with the air barely moving. The other passes just above the roof with the air moving fast. We would get the same result in a somewhat more cumbersome manner.

Try it yourself A 2.0 m × 2.0 m canvas covers a trailer. The trailer moves at 29 m/s (65 mi/h). Determine the net force exerted on the canvas by the air above and below it.

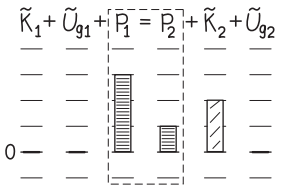
Answer An upward force of 2200 N (about 500 lb). No wonder the canvas covering a truck trailer moving on a highway balloons outward.



Dislodging plaque

The physical principles of a roof being lifted from a house also explain how plaque can become dislodged from the inner wall of an artery. Plaque may block a considerable portion of the area where blood normally flows. Suppose the radius of the vessel opening is one-third its normal value because of the plaque. Then the area available for blood flow, proportional to r^2, is about one-ninth the normal value. The speed of flow in the narrowed portion of the artery will be about nine times greater than in the unblocked part of the vessel. The kinetic energy density term in Bernoulli's equation is proportional to v^2 and therefore is 81 times greater in the constricted area than in the open part of the vessel.

Notice that in Bernoulli's equation, the sum of the gravitational potential energy density, the kinetic energy density, and the pressure at one location should equal the sum of the same three terms at some other location along a streamline in the blood. As blood speeds by the plaque, its kinetic energy density is 81 times greater, and consequently its pressure is much less than the pressure in the open vessel just before and just after the plaque. This pressure differential could cause the plaque to be pushed off the wall and tumble downstream, causing a blood clot (a process called thrombosis). Let's estimate the net force that the blood exerts on the plaque.



EXAMPLE 14.4 **A clogged artery**

Blood flows through the unobstructed part of a blood vessel at a speed of 0.5 m/s. The blood then flows past a plaque that constricts the cross-sectional area to one-ninth the normal value. The surface area of the plaque parallel to the direction of blood flow is about $0.60\ \text{cm}^2 = 6.0 \times 10^{-5}\ \text{m}^2$. Estimate the net force that the fluid exerts on the plaque.

Sketch and translate A simplified two-dimensional sketch of three-dimensional the situation is shown above right. The third dimension is perpendicular to the page of the book. The plaque is as large in this dimension as in the x-dimension, but the area where it is attached to the top wall is very small. Point 1 is above the plaque in stationary blood pooled in a channel where the plaque attaches to the artery wall. Point 2 is in the bloodstream below the plaque, where blood flows rapidly past it. The net force depends on the differences in pressure at points 1 and 2. Thus, we need to first find the pressure difference. Since points 1 and 2 are not on the same streamline, we cannot automatically use Bernoulli's equation. But since the streamlines that do go through points 1 and 2 were side by side before they reached the plaque, each streamline will have the same $P + (1/2)\rho v^2 + \rho g y$ value. This means we can equate the $P + (1/2)\rho v^2 + \rho g y$ values at points 1 and 2.

Simplify and diagram Assume for simplicity that the blood is nonviscous and flows with laminar flow without turbulence. Assume also that the vertical distance between points 1 and 2 is small $(y_1 - y_2 \approx 0)$ and that the area of the stationary blood above the plaque is the same as the area where the blood moves below the plaque. A bar chart represents the process. The blood pressure at position 2 is less than at position 1 because the blood flows at high speed through the constricted artery, whereas it sits at rest in the channels at position 1$(v_1 = 0)$.

Represent mathematically Compare the two points using Bernoulli's equation:

$$\begin{aligned} P_1 - P_2 &= \tfrac{1}{2}\rho(v_2^2 - v_1^2) + \rho g(y_2 - y_1) \\ &= \tfrac{1}{2}\rho(v_2^2 - 0) + 0 = \tfrac{1}{2}\rho v_2^2 \end{aligned}$$

Since the cross-sectional area of the vessel at the location of the plaque is one-ninth its normal area (the radius is one-third the normal value), the blood must be flowing at nine times its normal speed. The net force exerted by the blood on the plaque downward and perpendicular to the direction the blood flows will be

$$\begin{aligned} F_{\text{net blood on P}\,y} &= F_{\text{blood 1 on P}} + (-F_{\text{blood 2 on P}}) \\ &= P_1A - P_2A = (P_1 - P_2)A \\ \Rightarrow F_{\text{net blood on P}\,y} &= \tfrac{1}{2}\rho v_2^2 A \end{aligned}$$

Solve and evaluate

$$\begin{aligned} F_{\text{net blood on P}\,y} &= \tfrac{1}{2}(1050\ \text{kg/m}^3)\,(9 \times 0.5\ \text{m/s})^2(6.0 \times 10^{-5}\ \text{m}^2) \\ &= 0.64\ \text{N} \approx 0.6\ \text{N} \end{aligned}$$

This is about the weight of one-half of an apple pulling on this tiny plaque. In addition, an "impact" force caused by blood hitting the plaque's upstream side contributes to the risk of breaking the plaque off the side wall of the vessel. The loose plaque can then tumble downstream and block blood flow in a smaller vessel in the heart (causing a heart attack) or in the brain (causing a stroke).

Try it yourself Air of density 1.3 kg/m^3 moves at speed 10 m/s across the top surface of a clarinet reed that has an area of 3 cm^2. The air below the reed is not moving and is at atmospheric pressure. Determine the net force exerted on the reed by the air above and below it.

Answer 0.02 N upward, toward the inside of the mouthpiece.

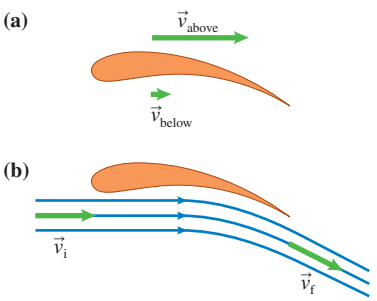
Using Bernoulli's equation to explain how airplanes fly

You may have heard that airplanes can fly because of the special shape of their wings, which causes the air above the wing to move faster than the air below the wing ($\vec{v}_{\text{above}} > \vec{v}_{\text{below}}$, shown in **Figure 14.10a**). Let us apply Bernoulli's equation to an airplane wing to evaluate this claim. A Boeing 747-8's maximum takeoff mass is 442 metric tons, its takeoff speed is 330 km/h, and its wing surface area is 554 m^2. We assume that the speed of air above the wing is equal to the takeoff speed and the speed of air below the wing is zero (this is a rather unrealistic assumption, but it allows us to estimate the largest possible force due to Bernoulli's effect). In this case we find

$$\Delta p = \tfrac{1}{2}\rho_{\text{air}} v_{\text{takeoff}}^2 = 0.5 \times (1.3\ \text{kg/m}^3) \times (92\ \text{m/s})^2 = 5501\ \text{N/m}^2$$

and

$$F_{\text{air on airplane}} = \Delta p \cdot A = 3.1 \times 10^6\ \text{N}$$



The force exerted by Earth on the airplane is

$$F_{\text{E on airplane}} = m_{\text{airplane}}\, g = 4.3 \times 10^6\ \text{N}$$

This force is much larger than the largest possible lifting force exerted on the plane due to Bernoulli's effect.

In other words, Bernoulli's effect is at work, but it does not provide a complete explanation of how airplanes fly. The important missing force comes from the change of direction of the air's motion. Due to the shape and the tilt of the wing, the air passing the wing changes its direction of motion from horizontal ($\vec{v}_{\text{i}}$) to slightly downward ($\vec{v}_{\text{f}}$) (Figure 14.10b). For this to happen, the wing must exert a downward force on the air; therefore (remember Newton's third law), the air exerts an equal and opposite force upward on the wing. It is this force that provides the main lift and (together with the force due to Bernoulli's effect) makes the airplane fly. Note that the origin of this force is the change of the direction of motion of air and has nothing to do with Bernoulli's effect.

FIGURE 14.10 Airflow over an airplane wing.

REVIEW QUESTION 14.5 In Example 14.2 we said that the pressure was the same at two levels when we drew the bar chart. Doesn't the pressure in a fluid increase with depth?

14.6 Viscous fluid flow

In our previous discussions and examples in this chapter, we assumed that there were no resistive forces exerted on the moving fluid or that fluids flow without friction. That is, we assumed no interaction either between the fluid and the walls of the pipes it flows in, or between the layers of the fluid. However, in Example 14.2 we found that this assumption was not reasonable. In fact, for many processes, such as the transport of blood in the small vessels in our bodies, fluid friction is very important. When we cannot neglect this friction inside the fluid, we call the fluid **viscous**.

Consider the following situation. You have an object that can slide on a frictionless horizontal surface, say, a puck on smooth ice. You push the puck abruptly and then let go. What happens to the puck? Once in motion, the puck will continue to slide at constant speed with respect to the ice even if nothing else pushes it. However, if there is friction between the contacting surfaces (there is a little sand in the ice), then the puck starts slowing down; for it to continue moving at constant speed, someone or something has to push it forward to balance the opposing friction force.

By analogy, if a fluid flows through a horizontal tube without friction (nonviscous fluid), we would expect it to continue to flow at a constant rate with no additional forward pressure. But if friction is present (the fluid is viscous), there must be greater pressure at the back of the fluid than at the front of the fluid to maintain a constant flow rate. If this is the case, the force exerted on any volume of the fluid due to the forward pressure is greater than the force exerted on the same volume of the fluid due to the pressure in the opposite direction.

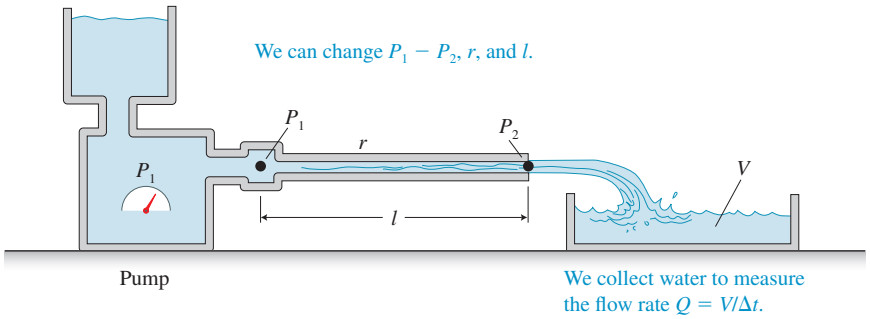
Factors that affect fluid flow rate

What factors affect the flow rate in the vessel with friction? What is the functional dependence of those factors? Let's think about the physical properties of the fluid and the vessel that can affect the flow rate. The following quantities might be important.

Pressure difference The flow rate should depend on how hard the fluid is pushed forward, that is, on the difference between the fluid pressure pushing forward from behind and the fluid pressure pushing back from in front of the fluid, or $(P_1 - P_2)$.

Radius of the tube The radius r of the tube carrying the fluid should affect the flow rate. From everyday experience we know that it is more difficult to push (a greater pressure difference) fluid through a tube of tiny radius than through a tube with a large radius.

Length of the tube The length l of the tube might also affect the ease of fluid flow. A long tube offers more resistance to flow than a shorter tube.



Fluid type Water flows much more easily than molasses does. Thus some property of a fluid that characterizes its "thickness" or "stickiness" should affect the flow.

Let's design an experiment to investigate exactly how the first three of these four factors (P, r, and l) affect the fluid flow rate Q. As shown in **Figure 14.11**, a pump that produces an adjustable pressure P_1 causes fluid to flow through tubes of different radii r and lengths l. We collect the fluid exiting the tube and measure the flow rate Q, which is the volume V of fluid leaving the tube in a certain time interval Δt divided by that time interval. The results of the experiments are reported in **Table 14.3**.

How is the flow rate affected by each of the three factors?

Pressure difference Looking at the first three rows of the table, we notice that the flow rate is proportional to the pressure difference $(Q \propto P_1 - P_2)$.

FIGURE 14.11 How do $P_1 - P_2$, r, and l affect the flow rate Q?

Radius of the tube Looking at rows 1, 4, and 5, we notice that the flow rate increases rapidly as the radius increases. Doubling the radius causes the flow rate to increase by a factor of 16 (2^4). Tripling the radius causes the flow rate to increase by a factor of 81 (3^4). It seems that the flow rate is proportional to the fourth power of the radius of the tube $(Q \propto r^4)$.

Length of the tube Looking at rows 1, 6, and 7, we notice that the flow rate decreases as the length of the tube increases. It seems that the flow rate is proportional to the inverse of the length $(Q \propto 1/l)$.

These three relationships can be combined in a single equation:

$$Q \propto \frac{r^4(P_1 - P_2)}{l}$$

The equation has been confirmed by numerous experiments.

TABLE 14.3 Different quantities affect the flow rate Q of fluid through a tube (data are reported in relative units)

$P_1 - P_2$ (Pressure difference)	r (Radius)	l (Length)	Q (Flow rate)
1	1	1	1
2	1	1	2
3	1	1	3
1	2	1	16
1	3	1	81
1	1	2	0.5
1	1	3	0.33

Viscosity and Poiseuille's law

In this experiment we did not investigate the fourth factor: the type of fluid. Under the same conditions, water flows faster than oil, which flows faster than molasses. If we use the same pressure difference to push different fluids through the same tube, we find that the fluids have different flow rates. The quantity by which we measure this effect on flow rate is called the **viscosity** η of the fluid. The flow rate is inversely proportional to viscosity:

$$Q \propto \frac{1}{\eta}$$

In 1840, using an experiment similar to that described above, French physician and physiologist Jean Louis Marie Poiseuille established a relationship between these physical quantities. However, instead of writing the flow rate in terms of the other four quantities, he wrote an expression for the pressure difference needed to cause a particular flow rate.

Poiseuille's law The forward-backward pressure difference $P_1 - P_2$ needed to cause a fluid of viscosity η to flow at a rate Q through a vessel of radius r and length l is

$$P_1 - P_2 = \left(\frac{8}{\pi}\right)\frac{\eta l}{r^4}Q \qquad (14.7)$$

The pressure difference term $P_1 - P_2$ on the left side of Poiseuille's law determines the net force pushing the fluid. The flow rate Q on the far right side is a consequence of this net push on the fluid. The term before Q on the right side (the $\left(\frac{8}{\pi}\right)\frac{\eta l}{r^4}$ term) can be thought of as the resistance of the fluid to flow: the same pressure difference will produce a smaller flow rate if the resistance is greater. The resistance is greater if the fluid has greater viscosity η, is greater for a longer tube (greater l), and is far more resistive if the vessel through which the fluid flows has a smaller radius ($1/r^4$ is much greater

TIP Notice that the pressure difference needed to cause a particular flow rate is proportional to the inverse of the fourth power of the radius of the vessel. If the radius of a vessel carrying fluid is reduced by a factor of 0.5, the pressure difference needed to cause the same flow rate must increase by $(1/0.5)^4 = 16$. We need 16 times the pressure difference to cause the same flow rate.

TABLE 14.4 Viscosities of some liquids and gases

Substance	Viscosity η $(\mathrm{N \cdot s/m^2})$
Air (30 °C)	1.9×10^{-5}
Water vapor (30 °C)	1.25×10^{-5}
Water (0 °C)	1.8×10^{-3}
Water (20 °C)	1.0×10^{-3}
Water (40 °C)	0.66×10^{-3}
Water (80 °C)	0.36×10^{-3}
Blood, whole (37 °C)	4×10^{-3}
Oil, SAE No. 10	0.20

for small r). This idea has many applications relative to the circulatory system—see the example a little later in this section.

From Poiseuille's law we can determine the unit for viscosity. To do this, we express the viscosity using other quantities in Eq. (14.7):

$$P_1 - P_2 = \left(\frac{8}{\pi}\right)\frac{\eta l}{r^4}Q \Rightarrow \eta = \frac{(P_1 - P_2)r^4\pi}{8Ql}$$

We use the latter equation to find the units for the viscosity. Remember that the units of pressure are

$$\mathrm{Pa} = \frac{\mathrm{N}}{\mathrm{m^2}} = \frac{\mathrm{kg \cdot m}}{\mathrm{s^2 \cdot m^2}} = \frac{\mathrm{kg}}{\mathrm{s^2 \cdot m}}$$

and the units for flow rate are $\mathrm{m^3/s}$. Using these units, we get

$$\eta = \frac{(\mathrm{kg})(\mathrm{m^4})(\mathrm{s})}{(\mathrm{s^2 \cdot m})(\mathrm{m^3})(\mathrm{m})} = \frac{\mathrm{kg}}{\mathrm{s \cdot m}}$$

We can also rewrite the last combination of units as $\mathrm{N \cdot s/m^2}$. Remember that $\mathrm{N/m^2} = \mathrm{Pa}$; thus the unit for viscosity can be written $\mathrm{Pa \cdot s}$. A list of viscosities of several fluids appears in **Table 14.4** using $\mathrm{N \cdot s/m^2}$ for the units of η.

QUANTITATIVE EXERCISE 14.5 **Blood flow through a narrow artery**

Because of plaque buildup, the radius of an artery in a person's heart decreases by 40%. Determine the ratio of the present flow rate to the original flow rate if the pressure across the artery, its length, and the viscosity of blood are unchanged.

Represent mathematically In this exercise, we are interested in the change in the flow rate and not in the change in pressure. Consequently, we rearrange Poiseuille's law for the flow rate in terms of the other quantities:

$$Q = \left(\frac{\pi}{8}\right)\left(\frac{\Delta P}{\eta l}\right)r^4$$

If the radius decreases by 40%, the new radius is 100% − 40% = 60% of the original. Thus the radius r of the vessel at the present time is related to the radius r_0 years earlier by the equation $r = 0.60r_0$.

Solve and evaluate The ratio of the flow rates is

$$\frac{Q}{Q_0} = \frac{\left(\frac{\pi}{8}\right)\left(\frac{\Delta P}{\eta l}\right)r^4}{\left(\frac{\pi}{8}\right)\left(\frac{\Delta P}{\eta l}\right)r_0^4} = \frac{r^4}{r_0^4} = \left(\frac{r}{r_0}\right)^4 = (0.60)^4 = 0.13$$

The flow rate is only 13% of the original flow rate! To compensate for such a dramatically reduced flow rate, the person's blood pressure will increase.

Try it yourself Determine the reduction in flow rate, assuming a constant pressure difference, if the radius of the vessel is reduced 90% (to 0.10 times its original value). This is not an unusual reduction for people with high blood pressure.

Answer $Q/Q_0 = 0.0001$, or 0.01% of its original value!

Limitations of Poiseuille's law: Reynolds number

Poiseuille's law describes the flow of a fluid accurately only when the flow is laminar. Experiments indicate that to determine when the flow is laminar or turbulent, we need to calculate what is called the pipe **Reynolds number** R_e:

$$R_e = \frac{2\bar{v}r\rho}{\eta} \tag{14.8}$$

where $\bar{v}$ is the average speed of the fluid, ρ is its density, η is the viscosity, and r is the radius of the pipe that carries the fluid. Experiments show that if the Reynolds number is less than 2000, the fluid flow is laminar; if it is more than 3000, the flow is turbulent; and between 2000 and 3000 the flow is unstable and can be either laminar or turbulent.

The Reynolds number, used as a criterion to decide whether the flow inside a pipe is laminar or turbulent, came from experiments conducted in the 1880s by Osborne Reynolds. Using a glass pipe with flowing water inside, he adjusted a valve to control the speed of the water flow. He then added colored water to the stream and observed that when the speed of the water was low, the colored layer of water could be clearly seen inside the pipe. When the speed of water flow increased beyond a certain limit, the colored part would break apart into vortices and mix with the rest of the water. Reynolds expressed the criterion for the type of flow with a unitless number (hence the name the Reynolds number), which he derived by taking the ratio of the net force pushing the fluid and the resistive force opposing it.

The transition from laminar to turbulent flow is also observed when an object and fluid are moving relative to each other. Reynolds derived a similar criterion (expressed as a unitless number) for this phenomenon. In general, the flow in pipes remains laminar up to much larger R_e numbers than does the flow of a fluid around an object.

REVIEW QUESTION 14.6 Describe some of the physics-related effects on the cardiovascular system of medication that lowers the viscosity of blood.

14.7 Drag force

So far in this chapter all of our analyses have focused on a moving fluid. In Section 14.6 we were concerned with the resistive forces as fluids move through a tube. Now we focus on solid objects moving through a fluid—for example, a swimmer moving through water, a skydiver falling through the air, or a car traveling through air. As you know from experience, the fluid in these and in other cases exerts a resistive **drag force** on the object moving through the fluid. So far we have been neglecting this force in our mechanics problems. Now we will not only learn how to calculate this force but also learn whether our assumptions were reasonable: for example, is the resistive drag force indeed insignificant when people and objects fall from small and large heights?

Laminar drag force Imagine that an object moves relatively slowly through a fluid (for example, a marble sinking in oil). In this case the fluid flows around the solid object in streamline laminar flow, with no turbulence. However, the fluid does exert a drag force on the object. For a spherical object O of radius r moving at speed v through a liquid of viscosity η, the magnitude of this nonturbulent drag force $F_{\mathrm{D\,F\,on\,O}}$ exerted by fluid on the object is given by the equation

$$F_{\mathrm{D\,F\,on\,O}} = 6\pi\eta r v \tag{14.9}$$

This equation is called **Stokes's law**. Notice that the drag force is proportional to the speed of the object relative to the fluid and to the radius of the sphere.

Turbulent drag force A rock sinks in oil much faster than a small marble. In this case the motion of oil past the sinking rock is turbulent, and Eq. (14.9) does not apply. A different Reynolds number, called the object Reynolds number, can be used to determine whether the flow of fluid past an object is laminar or turbulent:

$$R_e = \frac{vl\rho}{\eta} \tag{14.10}$$

where v is the object's speed with respect to the fluid, l is the characteristic dimension of the object, in most cases the diameter, and ρ and η are the density and viscosity of the fluid. When the Reynolds number is calculated using this equation, the threshold value for laminar flow is 1. If the Reynolds number is much more than 1, the flow is

turbulent and we cannot use Stokes's law. In this case, a new equation for drag force applies:

$$F_{\text{D F on O}} \approx \tfrac{1}{2} C_{\text{D}} \rho A v^2 \tag{14.11}$$

where ρ is the density of fluid, A is the cross-sectional area of the object as seen along its line of motion, and C_{D} is a dimensionless number called the *drag coefficient*. The drag coefficient depends on the shape of the object (the lower the number, the smaller the drag force and the more laminar the flow past the object). For example, the drag coefficient for a sphere is 0.5 and for a dolphin it is 0.005.

Drag force exerted on a moving vehicle

Does Stokes's law apply to moving cars? At 60 mi/h (about 27 m/s), for a car about 2 m wide in air with density 1.3 kg/m^3 and viscosity 2×10^{-5} N · s/m^2, the estimated Reynolds number is

$$R_{\text{e}} = \frac{vl\rho}{\eta} = \frac{(27\ \text{m/s})(2\ \text{m})(1.3\ \text{kg/m}^3)}{(2 \times 10^{-5}\ \text{N} \cdot \text{s/m}^2)} \approx 4 \times 10^6$$

This is much more than 1. We need to use Eq. (14.11) for the drag force.

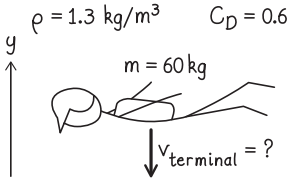
TIP Note that if the speed of a car doubles, the drag force exerted on it quadruples. Thus, because of air drag, when you increase your driving speed, you reduce your gas mileage.

We can estimate the magnitude of the drag force that air exerts on a compact car traveling at 27 m/s (60 mi/h) assuming that the drag coefficient C_{D} is approximately 0.3 for a well-designed car, the cross-sectional area of a car is 2 m^2, and the air density is 1.3 kg/m^3.

Because the flow of air past the car is turbulent, we use Eq. (14.11) to estimate the drag force that the air exerts on the car:

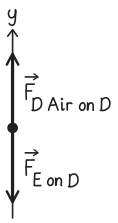
$$F_{\text{D Air on Car}} = \tfrac{1}{2} C_{\text{D}} \rho A v^2 = \tfrac{1}{2}(0.3)(1.3\ \text{kg/m}^3)(2\ \text{m}^2)(27\ \text{m/s})^2 = 280\ \text{N}$$

or a force of about 60 lb. Designing cars to minimize the drag force improves fuel efficiency.



Terminal speed

As a skydiver falls through the air, her speed increases, as does the drag force that the air exerts on her. Eventually, the diver's speed becomes so great that the magnitude of the upward resistive drag force that the air exerts on the diver equals the magnitude of the downward gravitational force that Earth exerts on the diver. The sum of the forces exerted on the diver is zero, so the diver moves downward at a constant speed, known as **terminal speed**. Let's estimate the terminal speed for a skydiver.



EXAMPLE 14.6 Terminal speed of skydiver

Estimate the terminal speed of a 60-kg skydiver falling through air of density 1.3 kg/m^3, assuming a drag coefficient $C_{\text{D}} = 0.6$.

Sketch and translate The situation is sketched here. When the diver is moving at terminal speed, the forces that the air exerts on the diver and that Earth exerts on the diver balance—the net force is zero. We choose the diver as the system of interest with vertical y-axis pointing upward.

Simplify and diagram A force diagram for the diver is shown to the right. Assume that the buoyant force that the air exerts on the diver is negligible in comparison to the other forces exerted on her and that the drag force involves turbulent airflow past the diver.

Represent mathematically Use the force diagram to help apply Newton's second law for the diver:

$$ma_y = \Sigma F_y$$
$$\Rightarrow 0 = F_{\text{D Air on D}} + (-F_{\text{E on D}})$$
$$= \tfrac{1}{2} C_{\text{D}} \rho A v_{\text{terminal}}^2 - mg$$

Solve and evaluate Solving for the diver's terminal speed gives

$$v_{\text{terminal}} = \sqrt{\frac{2mg}{C_D \rho A}}$$

All of the quantities in the above expression are known except the cross-sectional area of the diver along her line of motion. If we assume that she is 1.5 m tall and 0.3 m wide, her cross-sectional area is about 0.5 m^2. We find that her terminal speed is

$$v_{\text{terminal}} = \sqrt{\frac{2(60\text{ kg})(9.8\text{ N/kg})}{(0.6)(1.3\text{ kg/m}^3)(0.5\text{ m}^2)}} = 55\text{ m/s}$$

The unit is correct. The magnitude seems reasonable—about 120 mi/h.

Note that we assumed a turbulent drag force (Eq. (14.11). Was this assumption appropriate? To assess this, we will estimate the maximum speed of the diver for the drag force to be laminar. According to Eq. (14.10),

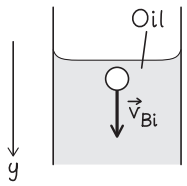
$$R_e = \frac{vl\rho}{\eta} \quad \Rightarrow \quad v = \frac{R_e \eta}{l\rho}$$

Estimating the characteristic dimension for the person to be about 1 m (somewhere between her 1.5-m height and 0.3-m width) and the critical value of the Reynolds number to be 1 for a laminar drag force, we obtain the following estimate for the greatest speed of an object for which the drag force exerted by the fluid is laminar:

$$v = \frac{R_e \eta}{l\rho} \approx \frac{1 \times (1.9 \times 10^{-5}\text{ N}\cdot\text{s/m}^2)}{(1\text{ m}) \times (1.3\text{ kg/m}^3)} \approx 1.5 \times 10^{-5}\text{ m/s}$$

This is a tiny speed—much too slow for a skydiver. Therefore, we could safely use the equation for turbulent drag force to estimate her speed.

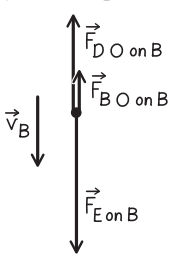
Try it yourself Suppose the diver pulled her legs to her chest so she was more in the shape of a ball. How qualitatively would that affect her terminal speed? Explain.



Answer Her cross-sectional area would be smaller, and according to the above equation, her terminal speed would be greater.

Below is an example of a problem whose solution depends on our assumptions. Being able to consider the effects of assumptions is a very useful skill.

EXAMPLE 14.7 Multiple possibility problem



A small metal ball is launched vertically downward, with initial velocity $\vec{v}_{\text{Bi}}$, from just below the surface of oil that fills a very deep container. Draw a qualitative velocity-versus-time and an acceleration-versus-time graph for the motion of the ball.

Sketch and translate We draw a sketch of the situation; let's choose the y-axis to point down. In order to draw velocity- and acceleration-versus-time graphs, we need to know the sum of the forces exerted on the ball.

Simplify and diagram The term "simplify" relates to the assumptions that we need to make to solve the problem. Given that one of the forces exerted on the ball is variable (the drag force), the assumptions we make about the initial velocity will determine the outcome. Therefore, in this case it is more useful to first identify the forces exerted on the ball and then consider different assumptions.

First, we need to identify the forces that are exerted on the ball and draw a force diagram (at right). Earth exerts a force $F_{\text{E on B}} = m_B g$ that points down. The oil exerts a buoyant force $F_{\text{B O on B}} = \rho_{\text{oil}} g V_B$ that points up. Since the ball is made of metal we know that $F_{\text{E on B}} > F_{\text{B O on B}}$. The oil also exerts a drag force $F_{\text{D O on B}}$ that is proportional to v_B and points opposite to $\vec{v}_B$ (up in our case). Given that we are interested in qualitative graphs, it is enough to remember that the drag force exerted by the oil on the ball is proportional to the speed of the ball with respect to the oil. This is true for a laminar as well as for a turbulent drag force.
