The algorithm first computes the primitive associate  $\check{m}_\alpha(z)$  of the minimal polynomial  $m_\alpha$  in  $\mathbb{Z}[z]$  and the primitive associates of  $f$  and  $g$  in  $\mathbb{Z}[x_1, \dots, x_{n-1}][z]/(\check{m}_\alpha)[x_0]$ . Then it computes the GCD in  $\mathbb{Q}(x_1, \dots, x_{n-1})[z]/(m_\alpha(z))[x_0]$ . This is done by calculating the GCD in  $\mathbb{Z}_p(x_1, \dots, x_{n-1})[z]/(\check{m}_\alpha(z))[x_0]$  for suitable primes  $p$  and then reconstructing the coefficients with the Chinese Remainder Theorem and Rational Reconstruction. The GCD over  $\mathbb{Z}_p(x_1, \dots, x_{n-1})[z]/(\check{m}_\alpha(z))[x_0]$  is computed with a recursive subroutine, which evaluates the polynomials at  $x_{n-1} = a$  for suitable evaluation points  $a \in \mathbb{Z}_p$  and then calls itself recursively until the ground domain does no longer contain any parameters. For  $\mathbb{Z}_p[z]/(\check{m}_\alpha(z))[x_0]$  the Euclidean Algorithm is used. The results of those recursive calls are then interpolated and Rational Function Reconstruction is used to obtain the correct coefficients. The results, both in  $\mathbb{Q}(x_1, \dots, x_{n-1})[z]/(m_\alpha(z))[x_0]$  and  $\mathbb{Z}_p(x_1, \dots, x_{n-1})[z]/(\check{m}_\alpha(z))[x_0]$ , are verified by a fraction free trial division.

Apart from the above GCD computation some GCDs in  $\mathbb{Q}(\alpha)[x_1, \dots, x_{n-1}]$  have to be calculated, because treating the polynomials as univariate ones can result in a spurious content of the GCD. For this `func_field_modgcd` is called recursively.

### Parameters

**f, g** : PolyElement

polynomials in  $\mathbb{Q}(\alpha)[x_0, \dots, x_{n-1}]$

### Returns

**h** : PolyElement

monic GCD of the polynomials  $f$  and  $g$

**cff** : PolyElement

cofactor of  $f$ , i.e.  $\frac{f}{h}$

**cfg** : PolyElement

cofactor of  $g$ , i.e.  $\frac{g}{h}$

## Examples

```
>>> from sympy.polys.modulargcd import func_field_modgcd
>>> from sympy.polys import AlgebraicField, QQ, ring
>>> from sympy import sqrt
```

```
>>> A = AlgebraicField(QQ, sqrt(2))
>>> R, x = ring('x', A)
```

```
>>> f = x**2 - 2
>>> g = x + sqrt(2)
```

```
>>> h, cff, cfg = func_field_modgcd(f, g)
```

```
>>> h == x + sqrt(2)
True
>>> cff * h == f
True
>>> cfg * h == g
True
```

```
>>> R, x, y = ring('x, y', A)
```

```
>>> f = x**2 + 2*sqrt(2)*x*y + 2*y**2
>>> g = x + sqrt(2)*y
```

```
>>> h, cff, cfg = func_field_modgcd(f, g)
```

```
>>> h == x + sqrt(2)*y
True
>>> cff * h == f
True
>>> cfg * h == g
True
```

```
>>> f = x + sqrt(2)*y
>>> g = x + y
```

```
>>> h, cff, cfg = func_field_modgcd(f, g)
```

```
>>> h == R.one
True
>>> cff * h == f
True
>>> cfg * h == g
True
```

## Undocumented

Many parts of the polys module are still undocumented, and even where there is documentation it is scarce. Please contribute!

## Series Manipulation using Polynomials

Any finite Taylor series, for all practical purposes is, in fact a polynomial. This module makes use of the efficient representation and operations of sparse polynomials for very fast multi-variate series manipulations. Typical speedups compared to SymPy's `series` method are in the range 20-100, with the gap widening as the series being handled gets larger.

All the functions expand any given series on some ring specified by the user. Thus, the coefficients of the calculated series depend on the ring being used. For example:

```
>>> from sympy.polys import ring, QQ, RR
>>> from sympy.polys.ring_series import rs_sin
>>> R, x, y = ring('x, y', QQ)
>>> rs_sin(x*y, x, 5)
-1/6*x**3*y**3 + x*y
```

QQ stands for the Rational domain. Here all coefficients are rationals. It is recommended to use QQ with ring series as it automatically chooses the fastest Rational type.

Similarly, if a Real domain is used:

```
>>> R, x, y = ring('x, y', RR)
>>> rs_sin(x*y, x, 5)
-0.166666666666667*x**3*y**3 + x*y
```

Though the definition of a polynomial limits the use of Polynomial module to Taylor series, we extend it to allow Laurent and even Puiseux series (with fractional exponents):

```
>>> from sympy.polys.ring_series import rs_cos, rs_tan
>>> R, x, y = ring('x, y', QQ)

>>> rs_cos(x + x*y, x, 3)/x**3
-1/2*x**(-1)*y**2 - x**(-1)*y - 1/2*x**(-1) + x**(-3)

>>> rs_tan(x**QQ(2, 5)*y**QQ(1, 2), x, 2)
1/3*x**(6/5)*y**(3/2) + x**(2/5)*y**(1/2)
```

By default, PolyElement did not allow non-natural numbers as exponents. It converted a fraction to an integer and raised an error on getting negative exponents. The goal of the ring series module is fast series expansion, and not to use the polys module. The reason we use it as our backend is simply because it implements a sparse representation and most of the

basic functions that we need. However, this default behaviour of polys was limiting for ring series.

Note that there is no such constraint (in having rational exponents) in the data-structure used by polys- dict. Sparse polynomials (PolyElement) use the Python dict to store a polynomial term by term, where a tuple of exponents is the key and the coefficient of that term is the value. There is no reason why we can't have rational values in the dict so as to support rational exponents.

So the approach we took was to modify sparse polys to allow non-natural exponents. And it turned out to be quite simple. We only had to delete the conversion to int of exponents in the `__pow__` method of PolyElement. So:

```
>>> x**QQ(3, 4)
x**(3/4)
```

and not 1 as was the case earlier.

Though this change violates the definition of a polynomial, it doesn't break anything yet. Ideally, we shouldn't modify polys in any way. But to have all the series capabilities we want, no other simple way was found. If need be, we can separate the modified part of polys from core polys. It would be great if any other elegant solution is found.

All series returned by the functions of this module are instances of the PolyElement class. To use them with other SymPy types, convert them to Expr:

```
>>> from sympy.polys.ring_series import rs_exp
>>> from sympy.abc import a, b, c
>>> series = rs_exp(x, x, 5)
>>> a + series.as_expr()
a + x**4/24 + x**3/6 + x**2/2 + x + 1
```

## rs\_series

Direct use of elementary ring series functions does give more control, but is limiting at the same time. Creating an appropriate ring for the desired series expansion and knowing which ring series function to call, are things not everyone might be familiar with.

*rs\_series* is a function that takes an arbitrary Expr and returns its expansion by calling the appropriate ring series functions. The returned series is a polynomial over the simplest (almost) possible ring that does the job. It recursively builds the ring as it parses the given expression, adding generators to the ring when it needs them. Some examples:

```
>>> from sympy.polys.ring_series import rs_series
>>> from sympy.functions.elementary.trigonometric import sin
>>> rs_series(sin(a + b), a, 5)
1/24*sin(b)*a**4 - 1/2*sin(b)*a**2 + sin(b) - 1/6*cos(b)*a**3 + cos(b)*a

>>> rs_series(sin(exp(a*b) + cos(a + c)), a, 2)
-sin(c)*cos(cos(c) + 1)*a + cos(cos(c) + 1)*a*b + sin(cos(c) + 1)

>>> rs_series(sin(a + b)*cos(a + c)*tan(a**2 + b), a, 2)
cos(b)*cos(c)*tan(b)*a - sin(b)*sin(c)*tan(b)*a + sin(b)*cos(c)*tan(b)
```

It can expand complicated multivariate expressions involving multiple functions and most importantly, it does so blazingly fast:

```
>>> %timeit ((sin(a) + cos(a))**10).series(a, 0, 5)
1 loops, best of 3: 1.33 s per loop

>>> %timeit rs_series((sin(a) + cos(a))**10, a, 5)
100 loops, best of 3: 4.13 ms per loop
```

*rs\_series* is over 300 times faster. Given an expression to expand, there is some fixed overhead to parse it. Thus, for larger orders, the speed improvement becomes more prominent:

```
>>> %timeit rs_series((sin(a) + cos(a))**10, a, 100)
10 loops, best of 3: 32.8 ms per loop
```

To figure out the right ring for a given expression, *rs\_series* uses the *sring* function, which in turn uses other functions of *polys*. As explained above, non-natural exponents are not allowed. But the restriction is on exponents and not generators. So, *polys* allows all sorts of symbolic terms as generators to make sure that the exponent is a natural number:

```
>>> from sympy.polys.rings import sring
>>> R, expr = sring(1/a**3 + a**QQ(3, 7)); R
Polynomial ring in 1/a, a**(1/7) over ZZ with lex order
```

In the above example,  $1/a$  and  $a^{1/7}$  will be treated as completely different atoms. For all practical purposes, we could let  $b = 1/a$  and  $c = a^{1/7}$  and do the manipulations. Effectively, expressions involving  $1/a$  and  $a^{1/7}$  (and their powers) will never simplify:

```
>>> expr*R(1/a)
(1/a)**4 + (1/a)*(a**(1/7))**3
```

This leads to similar issues with manipulating Laurent and Puiseux series as faced earlier. Fortunately, this time we have an elegant solution and are able to isolate the *series* and *polys* behaviour from one another. We introduce a boolean flag *series* in the list of allowed Options for polynomials (see [sympy.polys.polyoptions.Options](#) (page 2642)). Thus, when we want *sring* to allow rational exponents we supply a *series=True* flag to *sring*:

```
>>> rs_series(sin(a**QQ(1, 3)), a, 3)
-1/5040*a**(7/3) + 1/120*a**(5/3) - 1/6*a + a**(1/3)
```

## Contribute

*rs\_series* is not fully implemented yet. As of now, it supports only multivariate Taylor expansions of expressions involving *sin*, *cos*, *exp* and *tan*. Adding the remaining functions is not at all difficult and they will be gradually added. If you are interested in helping, read the comments in *ring\_series.py*. Currently, it does not support Puiseux series (though the elementary functions do). This is expected to be fixed soon.

You can also add more functions to *ring\_series.py*. Only elementary functions are supported currently. The long term goal is to replace SymPy's current *series* method with *rs\_series*.

## Manipulation of power series

Functions in this module carry the prefix `rs_`, standing for “ring series”. They manipulate finite power series in the sparse representation provided by `polys.ring.ring`.

### Elementary functions

`sympy.polys.ring_series.rs_log(p, x, prec)`

The Logarithm of  $p$  modulo  $O(x^{**prec})$ .

### Notes

Truncation of integral  $\int x^{p-1} dp/dx$  is used.

### Examples

```
>>> from sympy.polys.domains import QQ
>>> from sympy.polys.rings import ring
>>> from sympy.polys.ring_series import rs_log
>>> R, x = ring('x', QQ)
>>> rs_log(1 + x, x, 8)
1/7*x**7 - 1/6*x**6 + 1/5*x**5 - 1/4*x**4 + 1/3*x**3 - 1/2*x**2 + x
>>> rs_log(x**QQ(3, 2) + 1, x, 5)
1/3*x**(9/2) - 1/2*x**3 + x**(3/2)
```

`sympy.polys.ring_series.rs_LambertW(p, x, prec)`

Calculate the series expansion of the principal branch of the Lambert W function.

### Examples

```
>>> from sympy.polys.domains import QQ
>>> from sympy.polys.rings import ring
>>> from sympy.polys.ring_series import rs_LambertW
>>> R, x, y = ring('x, y', QQ)
>>> rs_LambertW(x + x*y, x, 3)
-x**2*y**2 - 2*x**2*y - x**2 + x*y + x
```

### See also:

[\*LambertW\*](#) (page 412)

`sympy.polys.ring_series.rs_exp(p, x, prec)`

Exponentiation of a series modulo  $O(x^{**prec})$

## Examples

```
>>> from sympy.polys.domains import QQ
>>> from sympy.polys.rings import ring
>>> from sympy.polys.ring_series import rs_exp
>>> R, x = ring('x', QQ)
>>> rs_exp(x**2, x, 7)
1/6*x**6 + 1/2*x**4 + x**2 + 1
```

`sympy.polys.ring_series.rs_atan(p, x, prec)`

The arctangent of a series

Return the series expansion of the atan of p, about 0.

## Examples

```
>>> from sympy.polys.domains import QQ
>>> from sympy.polys.rings import ring
>>> from sympy.polys.ring_series import rs_atan
>>> R, x, y = ring('x, y', QQ)
>>> rs_atan(x + x*y, x, 4)
-1/3*x**3*y**3 - x**3*y**2 - x**3*y - 1/3*x**3 + x*y + x
```

### See also:

[atan](#) (page 397)

`sympy.polys.ring_series.rs_asin(p, x, prec)`

Arcsine of a series

Return the series expansion of the asin of p, about 0.

## Examples

```
>>> from sympy.polys.domains import QQ
>>> from sympy.polys.rings import ring
>>> from sympy.polys.ring_series import rs_asin
>>> R, x, y = ring('x, y', QQ)
>>> rs_asin(x, x, 8)
5/112*x**7 + 3/40*x**5 + 1/6*x**3 + x
```

### See also:

[asin](#) (page 395)

`sympy.polys.ring_series.rs_tan(p, x, prec)`

Tangent of a series.

Return the series expansion of the tan of p, about 0.

## Examples

```
>>> from sympy.polys.domains import QQ
>>> from sympy.polys.rings import ring
>>> from sympy.polys.ring_series import rs_tan
>>> R, x, y = ring('x, y', QQ)
>>> rs_tan(x + x*y, x, 4)
1/3*x**3*y**3 + x**3*y**2 + x**3*y + 1/3*x**3 + x*y + x
```

### See also:

[`\_tan1`](#) (page 2656), [`tan`](#) (page 391)

`sympy.polys.ring_series._tan1(p, x, prec)`

Helper function of `rs_tan()` (page 2655).

Return the series expansion of tan of a univariate series using Newton's method. It takes advantage of the fact that series expansion of atan is easier than that of tan.

Consider  $f(x) = y - \arctan(x)$  Let  $r$  be a root of  $f(x)$  found using Newton's method. Then  $f(r) = 0$  Or  $y = \arctan(x)$  where  $x = \tan(y)$  as required.

`sympy.polys.ring_series.rs_cot(p, x, prec)`

Cotangent of a series

Return the series expansion of the cot of  $p$ , about 0.

## Examples

```
>>> from sympy.polys.domains import QQ
>>> from sympy.polys.rings import ring
>>> from sympy.polys.ring_series import rs_cot
>>> R, x, y = ring('x, y', QQ)
>>> rs_cot(x, x, 6)
-2/945*x**5 - 1/45*x**3 - 1/3*x + x**(-1)
```

### See also:

[`cot`](#) (page 392)

`sympy.polys.ring_series.rs_sin(p, x, prec)`

Sine of a series

Return the series expansion of the sin of  $p$ , about 0.

## Examples

```
>>> from sympy.polys.domains import QQ
>>> from sympy.polys.rings import ring
>>> from sympy.polys.ring_series import rs_sin
>>> R, x, y = ring('x, y', QQ)
>>> rs_sin(x + x*y, x, 4)
-1/6*x**3*y**3 - 1/2*x**3*y**2 - 1/2*x**3*y - 1/6*x**3 + x*y + x
```

(continues on next page)

(continued from previous page)

```
>>> rs_sin(x**QQ(3, 2) + x*y**QQ(7, 5), x, 4)
-1/2*x**(7/2)*y**(14/5) - 1/6*x**3*y**(21/5) + x**(3/2) + x*y**(7/5)
```

**See also:**[sin](#) (page 389)`sympy.polys.ring_series.rs_cos(p, x, prec)`

Cosine of a series

Return the series expansion of the cos of p, about 0.

**Examples**

```
>>> from sympy.polys.domains import QQ
>>> from sympy.polys.rings import ring
>>> from sympy.polys.ring_series import rs_cos
>>> R, x, y = ring('x, y', QQ)
>>> rs_cos(x + x*y, x, 4)
-1/2*x**2*y**2 - x**2*y - 1/2*x**2 + 1
>>> rs_cos(x + x*y, x, 4)/x**QQ(7, 5)
-1/2*x**(3/5)*y**2 - x**(3/5)*y - 1/2*x**(3/5) + x**(-7/5)
```

**See also:**[cos](#) (page 390)`sympy.polys.ring_series.rs_cos_sin(p, x, prec)`Return the tuple (`rs_cos(p, x, prec)`, `rs_sin(p, x, prec)`).Is faster than calling `rs_cos` and `rs_sin` separately`sympy.polys.ring_series.rs_atanh(p, x, prec)`

Hyperbolic arctangent of a series

Return the series expansion of the atanh of p, about 0.

**Examples**

```
>>> from sympy.polys.domains import QQ
>>> from sympy.polys.rings import ring
>>> from sympy.polys.ring_series import rs_atanh
>>> R, x, y = ring('x, y', QQ)
>>> rs_atanh(x + x*y, x, 4)
1/3*x**3*y**3 + x**3*y**2 + x**3*y + 1/3*x**3 + x*y + x
```

**See also:**[atanh](#) (page 406)`sympy.polys.ring_series.rs_sinh(p, x, prec)`

Hyperbolic sine of a series

Return the series expansion of the sinh of p, about 0.

## Examples

```
>>> from sympy.polys.domains import QQ
>>> from sympy.polys.rings import ring
>>> from sympy.polys.ring_series import rs_sinh
>>> R, x, y = ring('x, y', QQ)
>>> rs_sinh(x + x*y, x, 4)
1/6*x**3*y**3 + 1/2*x**3*y**2 + 1/2*x**3*y + 1/6*x**3 + x*y + x
```

### See also:

[\*sinh\*](#) (page 402)

`sympy.polys.ring_series.rs_cosh(p, x, prec)`

Hyperbolic cosine of a series

Return the series expansion of the cosh of p, about 0.

## Examples

```
>>> from sympy.polys.domains import QQ
>>> from sympy.polys.rings import ring
>>> from sympy.polys.ring_series import rs_cosh
>>> R, x, y = ring('x, y', QQ)
>>> rs_cosh(x + x*y, x, 4)
1/2*x**2*y**2 + x**2*y + 1/2*x**2 + 1
```

### See also:

[\*cosh\*](#) (page 403)

`sympy.polys.ring_series.rs_tanh(p, x, prec)`

Hyperbolic tangent of a series

Return the series expansion of the tanh of p, about 0.

## Examples

```
>>> from sympy.polys.domains import QQ
>>> from sympy.polys.rings import ring
>>> from sympy.polys.ring_series import rs_tanh
>>> R, x, y = ring('x, y', QQ)
>>> rs_tanh(x + x*y, x, 4)
-1/3*x**3*y**3 - x**3*y**2 - x**3*y - 1/3*x**3 + x*y + x
```

### See also:

[\*tanh\*](#) (page 403)

`sympy.polys.ring_series.rs_hadamard_exp(p1, inverse=False)`

Return sum  $f_i/i!x^{**i}$  from sum  $f_ix^{**i}$ , where x is the first variable.

If `invers=True` return sum  $f_i*i!x^{**i}$

## Examples

```
>>> from sympy.polys.domains import QQ
>>> from sympy.polys.rings import ring
>>> from sympy.polys.ring_series import rs_hadamard_exp
>>> R, x = ring('x', QQ)
>>> p = 1 + x + x**2 + x**3
>>> rs_hadamard_exp(p)
1/6*x**3 + 1/2*x**2 + x + 1
```

## Operations

`sympy.polys.ring_series.rs_mul(p1, p2, x, prec)`

Return the product of the given two series, modulo  $O(x^{**prec})$ .

`x` is the series variable or its position in the generators.

## Examples

```
>>> from sympy.polys.domains import QQ
>>> from sympy.polys.rings import ring
>>> from sympy.polys.ring_series import rs_mul
>>> R, x = ring('x', QQ)
>>> p1 = x**2 + 2*x + 1
>>> p2 = x + 1
>>> rs_mul(p1, p2, x, 3)
3*x**2 + 3*x + 1
```

`sympy.polys.ring_series.rs_square(p1, x, prec)`

Square the series modulo  $O(x^{**prec})$

## Examples

```
>>> from sympy.polys.domains import QQ
>>> from sympy.polys.rings import ring
>>> from sympy.polys.ring_series import rs_square
>>> R, x = ring('x', QQ)
>>> p = x**2 + 2*x + 1
>>> rs_square(p, x, 3)
6*x**2 + 4*x + 1
```

`sympy.polys.ring_series.rs_pow(p1, n, x, prec)`

Return  $p1^{**n}$  modulo  $O(x^{**prec})$

### Examples

```
>>> from sympy.polys.domains import QQ
>>> from sympy.polys.rings import ring
>>> from sympy.polys.ring_series import rs_pow
>>> R, x = ring('x', QQ)
>>> p = x + 1
>>> rs_pow(p, 4, x, 3)
6*x**2 + 4*x + 1
```

`sympy.polys.ring_series.rs_series_inversion(p, x, prec)`  
Multivariate series inversion  $1/p$  modulo  $O(x^{**prec})$ .

### Examples

```
>>> from sympy.polys.domains import QQ
>>> from sympy.polys.rings import ring
>>> from sympy.polys.ring_series import rs_series_inversion
>>> R, x, y = ring('x, y', QQ)
>>> rs_series_inversion(1 + x*y**2, x, 4)
-x**3*y**6 + x**2*y**4 - x*y**2 + 1
>>> rs_series_inversion(1 + x*y**2, y, 4)
-x*y**2 + 1
>>> rs_series_inversion(x + x**2, x, 4)
x**3 - x**2 + x - 1 + x**(-1)
```

`sympy.polys.ring_series.rs_series_reversion(p, x, n, y)`  
Reversion of a series.

$p$  is a series with  $O(x^{**n})$  of the form  $p = ax + f(x)$  where  $a$  is a number different from 0.

$$f(x) = \sum_{k=2}^{n-1} a_k x_k$$

#### Parameters

**a\_k** : Can depend polynomially on other variables, not indicated.

**x** : Variable with name x. **y** : Variable with name y.

#### Returns

Solve  $p = y$ , that is, given  $ax + f(x) - y = 0$ ,

find the solution  $x = r(y)$  up to  $O(y^n)$ .

### Algorithm

If  $r_i$  is the solution at order  $i$ , then:  $ar_i + f(r_i) - y = O(y^{i+1})$

and if  $r_{i+1}$  is the solution at order  $i + 1$ , then:  $ar_{i+1} + f(r_{i+1}) - y = O(y^{i+2})$

We have,  $r_{i+1} = r_i + e$ , such that,  $ae + f(r_i) = O(y^{i+2})$  or  $e = -f(r_i)/a$

So we use the recursion relation:  $r_{i+1} = r_i - f(r_i)/a$  with the boundary condition:  $r_1 = y$

## Examples

```
>>> from sympy.polys.domains import QQ
>>> from sympy.polys.rings import ring
>>> from sympy.polys.ring_series import rs_series_reversion, rs_trunc
>>> R, x, y, a, b = ring('x, y, a, b', QQ)
>>> p = x - x**2 - 2*b*x**2 + 2*a*b*x**2
>>> p1 = rs_series_reversion(p, x, 3, y); p1
-2*y**2*a*b + 2*y**2*b + y**2 + y
>>> rs_trunc(p.compose(x, p1), y, 3)
y
```

`sympy.polys.ring_series.rs_nth_root(p, n, x, prec)`

Multivariate series expansion of the  $n$ th root of  $p$ .

### Parameters

**p** : Expr

The polynomial to computer the root of.

**n** : integer

The order of the root to be computed.

**x** : *PolyElement* (page 2554)

**prec** : integer

Order of the expanded series.

## Notes

The result of this function is dependent on the ring over which the polynomial has been defined. If the answer involves a root of a constant, make sure that the polynomial is over a real field. It cannot yet handle roots of symbols.

## Examples

```
>>> from sympy.polys.domains import QQ, RR
>>> from sympy.polys.rings import ring
>>> from sympy.polys.ring_series import rs_nth_root
>>> R, x, y = ring('x, y', QQ)
>>> rs_nth_root(1 + x + x*y, -3, x, 3)
2/9*x**2*y**2 + 4/9*x**2*y + 2/9*x**2 - 1/3*x*y - 1/3*x + 1
>>> R, x, y = ring('x, y', RR)
>>> rs_nth_root(3 + x + x*y, 3, x, 2)
0.160249952256379*x*y + 0.160249952256379*x + 1.44224957030741
```

`sympy.polys.ring_series.rs_trunc(p1, x, prec)`

Truncate the series in the  $x$  variable with precision  $prec$ , that is, modulo  $O(x^{**prec})$

## Examples

```
>>> from sympy.polys.domains import QQ
>>> from sympy.polys.rings import ring
>>> from sympy.polys.ring_series import rs_trunc
>>> R, x = ring('x', QQ)
>>> p = x**10 + x**5 + x + 1
>>> rs_trunc(p, x, 12)
x**10 + x**5 + x + 1
>>> rs_trunc(p, x, 10)
x**5 + x + 1
```

`sympy.polys.ring_series.rs_subs(p, rules, x, prec)`

Substitution with truncation according to the mapping in `rules`.

Return a series with precision `prec` in the generator `x`

Note that substitutions are not done one after the other

```
>>> from sympy.polys.domains import QQ
>>> from sympy.polys.rings import ring
>>> from sympy.polys.ring_series import rs_subs
>>> R, x, y = ring('x, y', QQ)
>>> p = x**2 + y**2
>>> rs_subs(p, {x: x+ y, y: x+ 2*y}, x, 3)
2*x**2 + 6*x*y + 5*y**2
>>> (x + y)**2 + (x + 2*y)**2
2*x**2 + 6*x*y + 5*y**2
```

which differs from

```
>>> rs_subs(rs_subs(p, {x: x+ y}, x, 3), {y: x+ 2*y}, x, 3)
5*x**2 + 12*x*y + 8*y**2
```

### Parameters

**p** : *PolyElement* (page 2554) Input series.

**rules** : dict with substitution mappings.

**x** : *PolyElement* (page 2554) in which the series truncation is to be done.

**prec** : *Integer* (page 987) order of the series after truncation.

## Examples

```
>>> from sympy.polys.domains import QQ
>>> from sympy.polys.rings import ring
>>> from sympy.polys.ring_series import rs_subs
>>> R, x, y = ring('x, y', QQ)
>>> rs_subs(x**2+y**2, {y: (x+y)**2}, x, 3)
6*x**2*y**2 + x**2 + 4*x*y**3 + y**4
```

`sympy.polys.ring_series.rs_diff(p, x)`

Return partial derivative of `p` with respect to `x`.

**Parameters**

**x** : *PolyElement* (page 2554) with respect to which p is differentiated.

**Examples**

```
>>> from sympy.polys.domains import QQ
>>> from sympy.polys.rings import ring
>>> from sympy.polys.ring_series import rs_diff
>>> R, x, y = ring('x, y', QQ)
>>> p = x + x**2*y**3
>>> rs_diff(p, x)
2*x*y**3 + 1
```

`sympy.polys.ring_series.rs_integrate(p, x)`

Integrate p with respect to x.

**Parameters**

**x** : *PolyElement* (page 2554) with respect to which p is integrated.

**Examples**

```
>>> from sympy.polys.domains import QQ
>>> from sympy.polys.rings import ring
>>> from sympy.polys.ring_series import rs_integrate
>>> R, x, y = ring('x, y', QQ)
>>> p = x + x**2*y**3
>>> rs_integrate(p, x)
1/3*x**3*y**3 + 1/2*x**2
```

`sympy.polys.ring_series.rs_newton(p, x, prec)`

Compute the truncated Newton sum of the polynomial p

**Examples**

```
>>> from sympy.polys.domains import QQ
>>> from sympy.polys.rings import ring
>>> from sympy.polys.ring_series import rs_newton
>>> R, x = ring('x', QQ)
>>> p = x**2 - 2
>>> rs_newton(p, x, 5)
8*x**4 + 4*x**2 + 2
```

`sympy.polys.ring_series.rs_compose_add(p1, p2)`

compute the composed sum  $\text{prod}(p2(x - \text{beta}))$  for beta root of p1)

## Examples

```
>>> from sympy.polys.domains import QQ
>>> from sympy.polys.rings import ring
>>> from sympy.polys.ring_series import rs_compose_add
>>> R, x = ring('x', QQ)
>>> f = x**2 - 2
>>> g = x**2 - 3
>>> rs_compose_add(f, g)
x**4 - 10*x**2 + 1
```

## References

[R730]

## Utility functions

`sympy.polys.ring_series.rs_is_puiseux(p, x)`

Test if *p* is Puiseux series in *x*.

Raise an exception if it has a negative power in *x*.

## Examples

```
>>> from sympy.polys.domains import QQ
>>> from sympy.polys.rings import ring
>>> from sympy.polys.ring_series import rs_is_puiseux
>>> R, x = ring('x', QQ)
>>> p = x**QQ(2,5) + x**QQ(2,3) + x
>>> rs_is_puiseux(p, x)
True
```

`sympy.polys.ring_series.rs_puiseux(f, p, x, prec)`

Return the puiseux series for  $f(p, x, prec)$ .

To be used when function *f* is implemented only for regular series.

## Examples

```
>>> from sympy.polys.domains import QQ
>>> from sympy.polys.rings import ring
>>> from sympy.polys.ring_series import rs_puiseux, rs_exp
>>> R, x = ring('x', QQ)
>>> p = x**QQ(2,5) + x**QQ(2,3) + x
>>> rs_puiseux(rs_exp, p, x, 1)
1/2*x**(4/5) + x**(2/3) + x**(2/5) + 1
```

`sympy.polys.ring_series.rs_puiseux2(f, p, q, x, prec)`

Return the puiseux series for  $f(p, q, x, prec)$ .

To be used when function *f* is implemented only for regular series.

`sympy.polys.ring_series.rs_series_from_list(p, c, x, prec, concur=1)`

Return a series  $\sum c[n] * p^{**n}$  modulo  $O(x^{**prec})$ .

It reduces the number of multiplications by summing concurrently.

$ax = [1, p, p^{**2}, \dots, p^{*(J-1)}]$   $s = \sum(c[i] * ax[i] \text{ for } i \text{ in } \text{range}(r, (r+1) * J)) * p^{*((K-1) * J)}$   
with  $K \geq (n+1)/J$

## Examples

```
>>> from sympy.polys.domains import QQ
>>> from sympy.polys.rings import ring
>>> from sympy.polys.ring_series import rs_series_from_list, rs_trunc
>>> R, x = ring('x', QQ)
>>> p = x**2 + x + 1
>>> c = [1, 2, 3]
>>> rs_series_from_list(p, c, x, 4)
6*x**3 + 11*x**2 + 8*x + 6
>>> rs_trunc(1 + 2*p + 3*p**2, x, 4)
6*x**3 + 11*x**2 + 8*x + 6
>>> pc = R.from_list(list(reversed(c)))
>>> rs_trunc(pc.compose(x, p), x, 4)
6*x**3 + 11*x**2 + 8*x + 6
```

`sympy.polys.ring_series.rs_fun(p, f, *args)`

Function of a multivariate series computed by substitution.

The case with `f` method name is used to compute `rs_tan` and `rs_nth_root` of a multivariate series:

`rs_fun(p, tan, iv, prec)`

`tan` series is first computed for a dummy variable `_x`, i.e., `rs_tan(_x, iv, prec)`. Then we substitute `_x` with `p` to get the desired series

## Parameters

**p** : *PolyElement* (page 2554) The multivariate series to be expanded.

**f** : *ring\_series* function to be applied on `p`.

**args[-2]** : *PolyElement* (page 2554) with respect to which, the series is to be expanded.

**args[-1]** : Required order of the expanded series.

## Examples

```
>>> from sympy.polys.domains import QQ
>>> from sympy.polys.rings import ring
>>> from sympy.polys.ring_series import rs_fun, _tan1
>>> R, x, y = ring('x, y', QQ)
>>> p = x + x*y + x**2*y + x**3*y**2
>>> rs_fun(p, _tan1, x, 4)
1/3*x**3*y**3 + 2*x**3*y**2 + x**3*y + 1/3*x**3 + x**2*y + x*y + x
```

`sympy.polys.ring_series.mul_xin(p, i, n)`

Return  $p * x_i * n$ .

$x_i$  is the  $i$ th variable in  $p$ .

`sympy.polys.ring_series.pow_xin(p, i, n)`

```
>>> from sympy.polys.domains import QQ
>>> from sympy.polys.rings import ring
>>> from sympy.polys.ring_series import pow_xin
>>> R, x, y = ring('x, y', QQ)
>>> p = x**QQ(2,5) + x + x**QQ(2,3)
>>> index = p.ring.gens.index(x)
>>> pow_xin(p, index, 15)
x**15 + x**10 + x**6
```

## Literature

The following is a non-comprehensive list of publications that were used as a theoretical foundation for implementing polynomials manipulation module.

## Poly solvers

This module provides functions for solving systems of linear equations that are used internally in sympy. Low-level linear systems solver.

### `solve_lin_sys`

`sympy.polys.solvers.solve_lin_sys(eqs, ring, _raw=True)`

Solve a system of linear equations from a PolynomialRing

#### Parameters

**eqs:** list[PolyElement]

The linear equations to be solved as elements of a PolynomialRing (assumed equal to zero).

**ring:** PolynomialRing

The polynomial ring from which eqs are drawn. The generators of this ring are the unknowns to be solved for and the domain of the ring is the domain of the coefficients of the system of equations.

**\_raw:** bool

If `_raw` is False, the keys and values in the returned dictionary will be of type Expr (and the unit of the field will be removed from the keys) otherwise the low-level polys types will be returned, e.g. PolyElement: PythonRational.

#### Returns

None if the system has no solution.

dict[Symbol, Expr] if `_raw=False`

dict[Symbol, DomainElement] if `_raw=True`.

### Explanation

Solves a system of linear equations given as PolyElement instances of a PolynomialRing. The basic arithmetic is carried out using instance of DomainElement which is more efficient than *Expr* (page 947) for the most common inputs.

While this is a public function it is intended primarily for internal use so its interface is not necessarily convenient. Users are suggested to use the *sympy.solvers.solve*.*linsolve()* (page 872) function (which uses this function internally) instead.

### Examples

```
>>> from sympy import symbols
>>> from sympy.polys.solvers import solve_lin_sys, sympy_eqs_to_ring
>>> x, y = symbols('x, y')
>>> eqs = [x - y, x + y - 2]
>>> eqs_ring, ring = sympy_eqs_to_ring(eqs, [x, y])
>>> solve_lin_sys(eqs_ring, ring)
{y: 1, x: 1}
```

Passing `_raw=False` returns the same result except that the keys are Expr rather than low-level poly types.

```
>>> solve_lin_sys(eqs_ring, ring, _raw=False)
{x: 1, y: 1}
```

### See also:

*sympy\_eqs\_to\_ring* (page 2668)

prepares the inputs to *solve\_lin\_sys*.

*linsolve* (page 872)

*linsolve* uses *solve\_lin\_sys* internally.

*sympy.solvers.solvers.solve* (page 836)

*solve* uses *solve\_lin\_sys* internally.

### eqs\_to\_matrix

*sympy.polys.solvers.eqs\_to\_matrix*(*eqs\_coeffs*, *eqs\_rhs*, *gens*, *domain*)

Get matrix from linear equations in dict format.

#### Parameters

**eqs\_coeffs:** list[dict[Symbol, DomainElement]]

The left hand sides of the equations as dicts mapping from symbols to coefficients where the coefficients are instances of DomainElement.

**eqs\_rhs:** list[DomainElements]

The right hand sides of the equations as instances of DomainElement.

**gens:** list[Symbol]

The unknowns in the system of equations.

**domain:** Domain

The domain for coefficients of both lhs and rhs.

**Returns**

The augmented matrix representation of the system as a DomainMatrix.

## Explanation

Get the matrix representation of a system of linear equations represented as dicts with low-level DomainElement coefficients. This is an *internal* function that is used by `solve_lin_sys`.

## Examples

```
>>> from sympy import symbols, ZZ
>>> from sympy.polys.solvers import eqs_to_matrix
>>> x, y = symbols('x, y')
>>> eqs_coeff = [{x:ZZ(1), y:ZZ(1)}, {x:ZZ(1), y:ZZ(-1)}]
>>> eqs_rhs = [ZZ(0), ZZ(-1)]
>>> eqs_to_matrix(eqs_coeff, eqs_rhs, [x, y], ZZ)
DomainMatrix([[1, 1, 0], [1, -1, 1]], (2, 3), ZZ)
```

**See also:**

[`solve\_lin\_sys`](#) (page 2666)

Uses `eqs_to_matrix()` (page 2667) internally

## `sympy_eqs_to_ring`

`sympy.polys.solvers.sympy_eqs_to_ring(eqs, symbols)`

Convert a system of equations from Expr to a PolyRing

**Parameters**

**eqs:** List of Expr

A list of equations as Expr instances

**symbols:** List of Symbol

A list of the symbols that are the unknowns in the system of equations.

**Returns**

Tuple[List[PolyElement], Ring]: The equations as PolyElement instances and the ring of polynomials within which each equation is represented.

## Explanation

High-level functions like `solve` expect `Expr` as inputs but can use `solve_lin_sys` internally. This function converts equations from `Expr` to the low-level poly types used by the `solve_lin_sys` function.

## Examples

```
>>> from sympy import symbols
>>> from sympy.polys.solvers import sympy_eqs_to_ring
>>> a, x, y = symbols('a, x, y')
>>> eqs = [x-y, x+a*y]
>>> eqs_ring, ring = sympy_eqs_to_ring(eqs, [x, y])
>>> eqs_ring
[x - y, x + a*y]
>>> type(eqs_ring[0])
<class 'sympy.polys.rings.PolyElement'>
>>> ring
ZZ(a)[x,y]
```

With the equations in this form they can be passed to `solve_lin_sys`:

```
>>> from sympy.polys.solvers import solve_lin_sys
>>> solve_lin_sys(eqs_ring, ring)
{y: 0, x: 0}
```

## `_solve_lin_sys`

`sympy.polys.solvers._solve_lin_sys(eqs_coeffs, eqs_rhs, ring)`

Solve a linear system from dict of PolynomialRing coefficients

## Explanation

This is an **internal** function used by `solve_lin_sys()` (page 2666) after the equations have been preprocessed. The role of this function is to split the system into connected components and pass those to `_solve_lin_sys_component()` (page 2670).

## Examples

Setup a system for  $x - y = 0$  and  $x + y = 2$  and solve:

```
>>> from sympy import symbols, sring
>>> from sympy.polys.solvers import _solve_lin_sys
>>> x, y = symbols('x, y')
>>> R, (xr, yr) = sring([x, y], [x, y])
>>> eqs = [{xr:R.one, yr:-R.one}, {xr:R.one, yr:R.one}]
>>> eqs_rhs = [R.zero, -2*R.one]
>>> _solve_lin_sys(eqs, eqs_rhs, R)
{y: 1, x: 1}
```

See also:

[`solve\_lin\_sys`](#) (page 2666)

This function is used internally by [`solve\_lin\_sys\(\)`](#) (page 2666).

### `_solve_lin_sys_component`

`sympy.polys.solvers._solve_lin_sys_component(eqs_coeffs, eqs_rhs, ring)`

Solve a linear system from dict of PolynomialRing coefficients

### Explanation

This is an **internal** function used by [`solve\_lin\_sys\(\)`](#) (page 2666) after the equations have been preprocessed. After [`\_solve\_lin\_sys\(\)`](#) (page 2669) splits the system into connected components this function is called for each component. The system of equations is solved using Gauss-Jordan elimination with division followed by back-substitution.

### Examples

Setup a system for  $x - y = 0$  and  $x + y = 2$  and solve:

```
>>> from sympy import symbols, sring
>>> from sympy.polys.solvers import _solve_lin_sys_component
>>> x, y = symbols('x, y')
>>> R, (xr, yr) = sring([x, y], [x, y])
>>> eqs = [{xr:R.one, yr:-R.one}, {xr:R.one, yr:R.one}]
>>> eqs_rhs = [R.zero, -2*R.one]
>>> _solve_lin_sys_component(eqs, eqs_rhs, R)
{y: 1, x: 1}
```

See also:

[`solve\_lin\_sys`](#) (page 2666)

This function is used internally by [`solve\_lin\_sys\(\)`](#) (page 2666).

## Introducing the domainmatrix of the poly module

This page introduces the idea behind domainmatrix which is used in SymPy's [`sympy.polys`](#) (page 2360) module. This is a relatively advanced topic so for a better understanding it is recommended to read about [`Domain`](#) (page 2504) and [`DDM`](#) (page 2690) along with [`sympy.matrices`](#) (page 1217) module.

## What is domainmatrix?

It is way of associating Matrix with *Domain* (page 2504).

A domainmatrix represents a matrix with elements that are in a particular Domain. Each domainmatrix internally wraps a DDM which is used for the lower-level operations. The idea is that the domainmatrix class provides the convenience routines for converting between Expr and the poly domains as well as unifying matrices with different domains.

**In general, we represent a matrix without concerning about the *Domain* (page 2504) as:**

```
>>> from sympy import Matrix
>>> from sympy.polys.matrices import DomainMatrix
>>> A = Matrix([
... [1, 2],
... [3, 4]])
>>> A
Matrix([
[1, 2],
[3, 4]])
```

## DomainMatrix Class Reference

```
class sympy.polys.matrices.domainmatrix.DomainMatrix(rows, shape, domain, *,
 fmt=None)
```

Associate Matrix with *Domain* (page 2504)

### Explanation

DomainMatrix uses *Domain* (page 2504) for its internal representation which makes it more faster for many common operations than current SymPy Matrix class, but this advantage makes it not entirely compatible with Matrix. DomainMatrix could be found analogous to numpy arrays with “dtype”. In the DomainMatrix, each matrix has a domain such as *ZZ* (page 2525) or *QQ<a>* (page 2539).

### Examples

Creating a DomainMatrix from the existing Matrix class:

```
>>> from sympy import Matrix
>>> from sympy.polys.matrices import DomainMatrix
>>> Matrix1 = Matrix([
... [1, 2],
... [3, 4]])
>>> A = DomainMatrix.from_Matrix(Matrix1)
>>> A
DomainMatrix({0: {0: 1, 1: 2}, 1: {0: 3, 1: 4}}, (2, 2), ZZ)
```

Directly forming a DomainMatrix:

```
>>> from sympy import ZZ
>>> from sympy.polys.matrices import DomainMatrix
>>> A = DomainMatrix([
... [ZZ(1), ZZ(2)],
... [ZZ(3), ZZ(4)]], (2, 2), ZZ)
>>> A
DomainMatrix([[1, 2], [3, 4]], (2, 2), ZZ)
```

**See also:**

[DDM](#) (page 2690), [SDM](#) (page 2692), [Domain](#) (page 2504), [Poly](#) (page 2378)

**add(B)**

Adds two DomainMatrix matrices of the same Domain

**Parameters**

**A, B: DomainMatrix**

matrices to add

**Returns**

DomainMatrix

DomainMatrix after Addition

**Raises**

**DMShapeError**

If the dimensions of the two DomainMatrix are not equal

**ValueError**

If the domain of the two DomainMatrix are not same

**Examples**

```
>>> from sympy import ZZ
>>> from sympy.polys.matrices import DomainMatrix
>>> A = DomainMatrix([
... [ZZ(1), ZZ(2)],
... [ZZ(3), ZZ(4)]], (2, 2), ZZ)
>>> B = DomainMatrix([
... [ZZ(4), ZZ(3)],
... [ZZ(2), ZZ(1)]], (2, 2), ZZ)
```

```
>>> A.add(B)
DomainMatrix([[5, 5], [5, 5]], (2, 2), ZZ)
```

**See also:**

[sub](#) (page 2686), [matmul](#) (page 2680)

**charpoly()**

Returns the coefficients of the characteristic polynomial of the DomainMatrix. These elements will be domain elements. The domain of the elements will be same as domain of the DomainMatrix.

**Returns**

list

coefficients of the characteristic polynomial

**Raises****DMNonSquareMatrixError**

If the DomainMatrix is not a not Square DomainMatrix

**Examples**

```
>>> from sympy import ZZ
>>> from sympy.polys.matrices import DomainMatrix
>>> A = DomainMatrix([
... [ZZ(1), ZZ(2)],
... [ZZ(3), ZZ(4)]], (2, 2), ZZ)
```

```
>>> A.charpoly()
[1, -5, -2]
```

**columnspace()**

Returns the columnspace for the DomainMatrix

**Returns**

DomainMatrix

The columns of this matrix form a basis for the columnspace.

**Examples**

```
>>> from sympy import QQ
>>> from sympy.polys.matrices import DomainMatrix
>>> A = DomainMatrix([
... [QQ(1), QQ(-1)],
... [QQ(2), QQ(-2)]], (2, 2), QQ)
>>> A.columnspace()
DomainMatrix([[1], [2]], (2, 1), QQ)
```

**convert\_to(K)**

Change the domain of DomainMatrix to desired domain or field

**Parameters****K** : Represents the desired domain or field.

Alternatively, None may be passed, in which case this method just returns a copy of this DomainMatrix.

**Returns**

DomainMatrix

DomainMatrix with the desired domain or field

### Examples

```
>>> from sympy import ZZ, ZZ_I
>>> from sympy.polys.matrices import DomainMatrix
>>> A = DomainMatrix([
... [ZZ(1), ZZ(2)],
... [ZZ(3), ZZ(4)]], (2, 2), ZZ)
```

```
>>> A.convert_to(ZZ_I)
DomainMatrix([[1, 2], [3, 4]], (2, 2), ZZ_I)
```

#### **det()**

Returns the determinant of a Square DomainMatrix

##### **Returns**

S.Complexes

determinant of Square DomainMatrix

##### **Raises**

##### **ValueError**

If the domain of DomainMatrix not a Field

### Examples

```
>>> from sympy import ZZ
>>> from sympy.polys.matrices import DomainMatrix
>>> A = DomainMatrix([
... [ZZ(1), ZZ(2)],
... [ZZ(3), ZZ(4)]], (2, 2), ZZ)
```

```
>>> A.det()
-2
```

#### **classmethod diag(*diagonal*, *domain*, *shape*=None)**

Return diagonal matrix with entries from *diagonal*.

### Examples

```
>>> from sympy.polys.matrices import DomainMatrix
>>> from sympy import ZZ
>>> DomainMatrix.diag([ZZ(5), ZZ(6)], ZZ)
DomainMatrix({0: {0: 5}, 1: {1: 6}}, (2, 2), ZZ)
```

#### **classmethod eye(*shape*, *domain*)**

Return identity matrix of size *n*

## Examples

```
>>> from sympy.polys.matrices import DomainMatrix
>>> from sympy import QQ
>>> DomainMatrix.eye(3, QQ)
DomainMatrix({0: {0: 1}, 1: {1: 1}, 2: {2: 1}}, (3, 3), QQ)
```

**classmethod** `from_Matrix(M, fmt='sparse', **kwargs)`

Convert Matrix to DomainMatrix

### Parameters

**M: Matrix**

### Returns

Returns DomainMatrix with identical elements as M

## Examples

```
>>> from sympy import Matrix
>>> from sympy.polys.matrices import DomainMatrix
>>> M = Matrix([
... [1.0, 3.4],
... [2.4, 1]])
>>> A = DomainMatrix.from_Matrix(M)
>>> A
DomainMatrix({0: {0: 1.0, 1: 3.4}, 1: {0: 2.4, 1: 1.0}}, (2, 2), RR)
```

We can keep internal representation as ddm using `fmt='dense'`

```
>>> from sympy import Matrix, QQ
>>> from sympy.polys.matrices import DomainMatrix
>>> A = DomainMatrix.from_Matrix(Matrix([[QQ(1, 2), QQ(3, 4)], [QQ(0, 1), QQ(0, 1)]]),
fmt='dense')
>>> A.rep
[[1/2, 3/4], [0, 0]]
```

### See also:

[Matrix](#) (page 1361)

**classmethod** `from_dict_sympy(nrows, ncols, elemsdict, **kwargs)`

### Parameters

**nrows: number of rows**

**ncols: number of cols**

**elemsdict: dict of dicts containing non-zero elements of the DomainMatrix**

### Returns

DomainMatrix containing elements of elemsdict

## Examples

```
>>> from sympy.polys.matrices import DomainMatrix
>>> from sympy.abc import x,y,z
>>> elemsdict = {0: {0:x}, 1:{1: y}, 2: {2: z}}
>>> A = DomainMatrix.from_dict_sympy(3, 3, elemsdict)
>>> A
DomainMatrix({0: {0: x}, 1: {1: y}, 2: {2: z}}, (3, 3), ZZ[x,y,z])
```

### See also:

[\*from\\_list\\_sympy\*](#) (page 2676)

**classmethod** `from_list(rows, domain)`

Convert a list of lists into a DomainMatrix

#### Parameters

**rows:** list of lists

Each element of the inner lists should be either the single arg, or tuple of args, that would be passed to the domain constructor in order to form an element of the domain. See examples.

#### Returns

DomainMatrix containing elements defined in rows

## Examples

```
>>> from sympy.polys.matrices import DomainMatrix
>>> from sympy import FF, QQ, ZZ
>>> A = DomainMatrix.from_list([[1, 0, 1], [0, 0, 1]], ZZ)
>>> A
DomainMatrix([[1, 0, 1], [0, 0, 1]], (2, 3), ZZ)
>>> B = DomainMatrix.from_list([[1, 0, 1], [0, 0, 1]], FF(7))
>>> B
DomainMatrix([[1 mod 7, 0 mod 7, 1 mod 7], [0 mod 7, 0 mod 7, 1 mod 7]], (2, 3), GF(7))
>>> C = DomainMatrix.from_list([(1, 2), (3, 1)], [(1, 4), (5, 1)]), QQ
>>> C
DomainMatrix([[1/2, 3], [1/4, 5]], (2, 2), QQ)
```

### See also:

[\*from\\_list\\_sympy\*](#) (page 2676)

**classmethod** `from_list_sympy(nrows, ncols, rows, **kwargs)`

Convert a list of lists of Expr into a DomainMatrix using `construct_domain`

#### Parameters

**nrows:** number of rows

**ncols:** number of columns

**rows:** list of lists

**Returns**

DomainMatrix containing elements of rows

**Examples**

```
>>> from sympy.polys.matrices import DomainMatrix
>>> from sympy.abc import x, y, z
>>> A = DomainMatrix.from_list_sympy(1, 3, [[x, y, z]])
>>> A
DomainMatrix([[x, y, z]], (1, 3), ZZ[x,y,z])
```

**See also:**

[sympy.polys.constructor.construct\\_domain](#) (page 2427), [from\\_dict\\_sympy](#) (page 2675)

**classmethod from\_rep(rep)**

Create a new DomainMatrix efficiently from DDM/SDM.

**Parameters**

**rep: SDM or DDM**

The internal sparse or dense representation of the matrix.

**Returns**

DomainMatrix

A *DomainMatrix* (page 2671) wrapping *rep*.

**Examples**

Create a *DomainMatrix* (page 2671) with an dense internal representation as *DDM* (page 2690):

```
>>> from sympy.polys.domains import ZZ
>>> from sympy.polys.matrices import DomainMatrix
>>> from sympy.polys.matrices.ddm import DDM
>>> drep = DDM([[ZZ(1), ZZ(2)], [ZZ(3), ZZ(4)]], (2, 2), ZZ)
>>> dM = DomainMatrix.from_rep(drep)
>>> dM
DomainMatrix([[1, 2], [3, 4]], (2, 2), ZZ)
```

Create a *DomainMatrix* (page 2671) with a sparse internal representation as *SDM* (page 2692):

```
>>> from sympy.polys.matrices import DomainMatrix
>>> from sympy.polys.matrices.sdm import SDM
>>> from sympy import ZZ
>>> drep = SDM({0:{1:ZZ(1)},1:{0:ZZ(2)}} , (2, 2), ZZ)
>>> dM = DomainMatrix.from_rep(drep)
>>> dM
DomainMatrix({0: {1: 1}, 1: {0: 2}}, (2, 2), ZZ)
```

## Notes

This takes ownership of *rep* as its internal representation. If *rep* is being mutated elsewhere then a copy should be provided to *from\_rep*. Only minimal verification or checking is done on *rep* as this is supposed to be an efficient internal routine.

### **hstack(\*B)**

Horizontally stack the given matrices.

#### **Parameters**

##### **B: DomainMatrix**

Matrices to stack horizontally.

#### **Returns**

DomainMatrix

DomainMatrix by stacking horizontally.

## Examples

```
>>> from sympy import ZZ
>>> from sympy.polys.matrices import DomainMatrix
```

```
>>> A = DomainMatrix([[ZZ(1), ZZ(2)], [ZZ(3), ZZ(4)]], (2, 2), ZZ)
>>> B = DomainMatrix([[ZZ(5), ZZ(6)], [ZZ(7), ZZ(8)]], (2, 2), ZZ)
>>> A.hstack(B)
DomainMatrix([[1, 2, 5, 6], [3, 4, 7, 8]], (2, 4), ZZ)
```

```
>>> C = DomainMatrix([[ZZ(9), ZZ(10)], [ZZ(11), ZZ(12)]], (2, 2), ZZ)
>>> A.hstack(B, C)
DomainMatrix([[1, 2, 5, 6, 9, 10], [3, 4, 7, 8, 11, 12]], (2, 6), ZZ)
```

### **See also:**

[\*unify\*](#) (page 2688)

### **inv()**

Finds the inverse of the DomainMatrix if exists

#### **Returns**

DomainMatrix

DomainMatrix after inverse

#### **Raises**

##### **ValueError**

If the domain of DomainMatrix not a Field

##### **DMNonSquareMatrixError**

If the DomainMatrix is not a not Square DomainMatrix

## Examples

```
>>> from sympy import QQ
>>> from sympy.polys.matrices import DomainMatrix
>>> A = DomainMatrix([
... [QQ(2), QQ(-1), QQ(0)],
... [QQ(-1), QQ(2), QQ(-1)],
... [QQ(0), QQ(0), QQ(2)]] , (3, 3), QQ)
>>> A.inv()
DomainMatrix([[2/3, 1/3, 1/6], [1/3, 2/3, 1/3], [0, 0, 1/2]], (3, 3),
↪ QQ)
```

### See also:

[neg](#) (page 2681)

### property is\_lower

Says whether this matrix is lower-triangular. True can be returned even if the matrix is not square.

### property is\_upper

Says whether this matrix is upper-triangular. True can be returned even if the matrix is not square.

### lu()

Returns Lower and Upper decomposition of the DomainMatrix

#### Returns

(L, U, exchange)

L, U are Lower and Upper decomposition of the DomainMatrix, exchange is the list of indices of rows exchanged in the decomposition.

#### Raises

##### ValueError

If the domain of DomainMatrix not a Field

## Examples

```
>>> from sympy import QQ
>>> from sympy.polys.matrices import DomainMatrix
>>> A = DomainMatrix([
... [QQ(1), QQ(-1)],
... [QQ(2), QQ(-2)]] , (2, 2), QQ)
>>> A.lu()
(DomainMatrix([[1, 0], [2, 1]], (2, 2), QQ), DomainMatrix([[1, -1],
↪ [0, 0]], (2, 2), QQ), [])
```

### See also:

[lu\\_solve](#) (page 2679)

### lu\_solve(rhs)

Solver for DomainMatrix x in the  $A*x = B$

**Parameters****rhs** : DomainMatrix B**Returns**

DomainMatrix

 $x$  in  $A*x = B$ **Raises****DMShapeError**

If the DomainMatrix A and rhs have different number of rows

**ValueError**

If the domain of DomainMatrix A not a Field

**Examples**

```
>>> from sympy import QQ
>>> from sympy.polys.matrices import DomainMatrix
>>> A = DomainMatrix([
... [QQ(1), QQ(2)],
... [QQ(3), QQ(4)]], (2, 2), QQ)
>>> B = DomainMatrix([
... [QQ(1), QQ(1)],
... [QQ(0), QQ(1)]], (2, 2), QQ)
```

```
>>> A.lu_solve(B)
DomainMatrix([[-2, -1], [3/2, 1]], (2, 2), QQ)
```

**See also:**[lu](#) (page 2679)**matmul(B)**

Performs matrix multiplication of two DomainMatrix matrices

**Parameters****A, B: DomainMatrix**

to multiply

**Returns**

DomainMatrix

DomainMatrix after multiplication

## Examples

```
>>> from sympy import ZZ
>>> from sympy.polys.matrices import DomainMatrix
>>> A = DomainMatrix([
... [ZZ(1), ZZ(2)],
... [ZZ(3), ZZ(4)]], (2, 2), ZZ)
>>> B = DomainMatrix([
... [ZZ(1), ZZ(1)],
... [ZZ(0), ZZ(1)]], (2, 2), ZZ)
```

```
>>> A.matmul(B)
DomainMatrix([[1, 3], [3, 7]], (2, 2), ZZ)
```

### See also:

[mul](#) (page 2681), [pow](#) (page 2683), [add](#) (page 2672), [sub](#) (page 2686)

### `mul(b)`

Performs term by term multiplication for the second DomainMatrix w.r.t first DomainMatrix. Returns a DomainMatrix whose rows are list of DomainMatrix matrices created after term by term multiplication.

#### Parameters

**A, B: DomainMatrix**

matrices to multiply term-wise

#### Returns

DomainMatrix

DomainMatrix after term by term multiplication

## Examples

```
>>> from sympy import ZZ
>>> from sympy.polys.matrices import DomainMatrix
>>> A = DomainMatrix([
... [ZZ(1), ZZ(2)],
... [ZZ(3), ZZ(4)]], (2, 2), ZZ)
>>> B = DomainMatrix([
... [ZZ(1), ZZ(1)],
... [ZZ(0), ZZ(1)]], (2, 2), ZZ)
```

```
>>> A.mul(B)
DomainMatrix([[DomainMatrix([[1, 1], [0, 1]], (2, 2), ZZ),
DomainMatrix([[2, 2], [0, 2]], (2, 2), ZZ)],
[DomainMatrix([[3, 3], [0, 3]], (2, 2), ZZ),
DomainMatrix([[4, 4], [0, 4]], (2, 2), ZZ)]], (2, 2), ZZ)
```

### See also:

[matmul](#) (page 2680)

**neg()**

Returns the negative of DomainMatrix

**Parameters****A** : Represents a DomainMatrix**Returns**

DomainMatrix

DomainMatrix after Negation

**Examples**

```
>>> from sympy import ZZ
>>> from sympy.polys.matrices import DomainMatrix
>>> A = DomainMatrix([
... [ZZ(1), ZZ(2)],
... [ZZ(3), ZZ(4)]], (2, 2), ZZ)
```

```
>>> A.neg()
DomainMatrix([[-1, -2], [-3, -4]], (2, 2), ZZ)
```

**nullspace()**

Returns the nullspace for the DomainMatrix

**Returns**

DomainMatrix

The rows of this matrix form a basis for the nullspace.

**Examples**

```
>>> from sympy import QQ
>>> from sympy.polys.matrices import DomainMatrix
>>> A = DomainMatrix([
... [QQ(1), QQ(-1)],
... [QQ(2), QQ(-2)]], (2, 2), QQ)
>>> A.nullspace()
DomainMatrix([[1, 1]], (1, 2), QQ)
```

**classmethod ones(*shape, domain*)**Returns a DomainMatrix of 1s, of size *shape*, belonging to the specified domain

## Examples

```
>>> from sympy.polys.matrices import DomainMatrix
>>> from sympy import QQ
>>> DomainMatrix.ones((2,3), QQ)
DomainMatrix([[1, 1, 1], [1, 1, 1]], (2, 3), QQ)
```

### **pow(*n*)**

Computes  $A^{**n}$

#### **Parameters**

**A** : DomainMatrix

**n** : exponent for A

#### **Returns**

DomainMatrix

DomainMatrix on computing  $A^{**n}$

#### **Raises**

**NotImplementedError**

if n is negative.

## Examples

```
>>> from sympy import ZZ
>>> from sympy.polys.matrices import DomainMatrix
>>> A = DomainMatrix([
... [ZZ(1), ZZ(1)],
... [ZZ(0), ZZ(1)]], (2, 2), ZZ)
```

```
>>> A.pow(2)
DomainMatrix([[1, 2], [0, 1]], (2, 2), ZZ)
```

#### **See also:**

[\*matmul\*](#) (page 2680)

### **rowspace()**

Returns the rowspace for the DomainMatrix

#### **Returns**

DomainMatrix

The rows of this matrix form a basis for the rowspace.

### Examples

```
>>> from sympy import QQ
>>> from sympy.polys.matrices import DomainMatrix
>>> A = DomainMatrix([
... [QQ(1), QQ(-1)],
... [QQ(2), QQ(-2)]]], (2, 2), QQ)
>>> A.rowspace()
DomainMatrix([[1, -1]], (1, 2), QQ)
```

#### **rref()**

Returns reduced-row echelon form and list of pivots for the DomainMatrix

##### **Returns**

(DomainMatrix, list)

reduced-row echelon form and list of pivots for the DomainMatrix

##### **Raises**

##### **ValueError**

If the domain of DomainMatrix not a Field

### Examples

```
>>> from sympy import QQ
>>> from sympy.polys.matrices import DomainMatrix
>>> A = DomainMatrix([
... [QQ(2), QQ(-1), QQ(0)],
... [QQ(-1), QQ(2), QQ(-1)],
... [QQ(0), QQ(0), QQ(2)]]], (3, 3), QQ)
```

```
>>> rref_matrix, rref_pivots = A.rref()
>>> rref_matrix
DomainMatrix([[1, 0, 0], [0, 1, 0], [0, 0, 1]], (3, 3), QQ)
>>> rref_pivots
(0, 1, 2)
```

#### **See also:**

[convert\\_to](#) (page 2673), [lu](#) (page 2679)

#### **scc()**

Compute the strongly connected components of a DomainMatrix

##### **Returns**

List of lists of integers

Each list represents a strongly connected component.

## Explanation

A square matrix can be considered as the adjacency matrix for a directed graph where the row and column indices are the vertices. In this graph if there is an edge from vertex  $i$  to vertex  $j$  if  $M[i, j]$  is nonzero. This routine computes the strongly connected components of that graph which are subsets of the rows and columns that are connected by some nonzero element of the matrix. The strongly connected components are useful because many operations such as the determinant can be computed by working with the submatrices corresponding to each component.

## Examples

Find the strongly connected components of a matrix:

```
>>> from sympy import ZZ
>>> from sympy.polys.matrices import DomainMatrix
>>> M = DomainMatrix([[ZZ(1), ZZ(0), ZZ(2)],
... [ZZ(0), ZZ(3), ZZ(0)],
... [ZZ(4), ZZ(6), ZZ(5)]]), (3, 3), ZZ)
>>> M.scc()
[[1], [0, 2]]
```

Compute the determinant from the components:

```
>>> MM = M.to_Matrix()
>>> MM
Matrix([
[1, 0, 2],
[0, 3, 0],
[4, 6, 5]])
>>> MM[[1], [1]]
Matrix([[3]])
>>> MM[[0, 2], [0, 2]]
Matrix([
[1, 2],
[4, 5]])
>>> MM.det()
-9
>>> MM[[1], [1]].det() * MM[[0, 2], [0, 2]].det()
-9
```

The components are given in reverse topological order and represent a permutation of the rows and columns that will bring the matrix into block lower-triangular form:

```
>>> MM[[1, 0, 2], [1, 0, 2]]
Matrix([
[3, 0, 0],
[0, 1, 2],
[6, 4, 5]])
```

## See also:

(page 1314), [\*sympy.utilities.iterables.strongly\\_connected\\_components\*](#)

(page 2094)

**sub(*B*)**

Subtracts two DomainMatrix matrices of the same Domain

**Parameters**

**A, B: DomainMatrix**

matrices to subtract

**Returns**

DomainMatrix

DomainMatrix after Subtraction

**Raises**

**DMShapeError**

If the dimensions of the two DomainMatrix are not equal

**ValueError**

If the domain of the two DomainMatrix are not same

**Examples**

```
>>> from sympy import ZZ
>>> from sympy.polys.matrices import DomainMatrix
>>> A = DomainMatrix([
... [ZZ(1), ZZ(2)],
... [ZZ(3), ZZ(4)]], (2, 2), ZZ)
>>> B = DomainMatrix([
... [ZZ(4), ZZ(3)],
... [ZZ(2), ZZ(1)]], (2, 2), ZZ)
```

```
>>> A.sub(B)
DomainMatrix([[-3, -1], [1, 3]], (2, 2), ZZ)
```

**See also:**

[add](#) (page 2672), [matmul](#) (page 2680)

**to\_Matrix()**

Convert DomainMatrix to Matrix

**Returns**

Matrix

MutableDenseMatrix for the DomainMatrix

### Examples

```
>>> from sympy import ZZ
>>> from sympy.polys.matrices import DomainMatrix
>>> A = DomainMatrix([
... [ZZ(1), ZZ(2)],
... [ZZ(3), ZZ(4)]], (2, 2), ZZ)
```

```
>>> A.to_Matrix()
Matrix([
 [1, 2],
 [3, 4]])
```

#### See also:

[`from\_Matrix`](#) (page 2675)

#### `to_dense()`

Return a dense DomainMatrix representation of *self*.

### Examples

```
>>> from sympy.polys.matrices import DomainMatrix
>>> from sympy import QQ
>>> A = DomainMatrix({0: {0: 1}, 1: {1: 2}}, (2, 2), QQ)
>>> A.rep
{0: {0: 1}, 1: {1: 2}}
>>> B = A.to_dense()
>>> B.rep
[[1, 0], [0, 2]]
```

#### `to_field()`

Returns a DomainMatrix with the appropriate field

##### Returns

DomainMatrix

DomainMatrix with the appropriate field

### Examples

```
>>> from sympy import ZZ
>>> from sympy.polys.matrices import DomainMatrix
>>> A = DomainMatrix([
... [ZZ(1), ZZ(2)],
... [ZZ(3), ZZ(4)]], (2, 2), ZZ)
```

```
>>> A.to_field()
DomainMatrix([[1, 2], [3, 4]], (2, 2), QQ)
```

#### `to_sparse()`

Return a sparse DomainMatrix representation of *self*.

## Examples

```
>>> from sympy.polys.matrices import DomainMatrix
>>> from sympy import QQ
>>> A = DomainMatrix([[1, 0],[0, 2]], (2, 2), QQ)
>>> A.rep
[[1, 0], [0, 2]]
>>> B = A.to_sparse()
>>> B.rep
{0: {0: 1}, 1: {1: 2}}
```

### **transpose()**

Matrix transpose of self

### **unify(\*others, fmt=None)**

Unifies the domains and the format of self and other matrices.

#### **Parameters**

**others** : DomainMatrix

**fmt**: string 'dense', 'sparse' or 'None' (default)

The preferred format to convert to if self and other are not already in the same format. If *None* or not specified then no conversion is performed.

#### **Returns**

Tuple[DomainMatrix]

Matrices with unified domain and format

## Examples

Unify the domain of DomainMatrix that have different domains:

```
>>> from sympy import ZZ, QQ
>>> from sympy.polys.matrices import DomainMatrix
>>> A = DomainMatrix([[ZZ(1), ZZ(2)]], (1, 2), ZZ)
>>> B = DomainMatrix([[QQ(1, 2), QQ(2)]]), (1, 2), QQ)
>>> Aq, Bq = A.unify(B)
>>> Aq
DomainMatrix([[1, 2]], (1, 2), QQ)
>>> Bq
DomainMatrix([[1/2, 2]], (1, 2), QQ)
```

Unify the format (dense or sparse):

```
>>> A = DomainMatrix([[ZZ(1), ZZ(2)]], (1, 2), ZZ)
>>> B = DomainMatrix({0:{0: ZZ(1)}}), (2, 2), ZZ)
>>> B.rep
{0: {0: 1}}
```

```
>>> A2, B2 = A.unify(B, fmt='dense')
>>> B2.rep
[[1, 0], [0, 0]]
```

**See also:**

[convert\\_to](#) (page 2673), [to\\_dense](#) (page 2687), [to\\_sparse](#) (page 2687)

**vstack(\*B)**

Vertically stack the given matrices.

**Parameters****B: DomainMatrix**

Matrices to stack vertically.

**Returns**

DomainMatrix

DomainMatrix by stacking vertically.

**Examples**

```
>>> from sympy import ZZ
>>> from sympy.polys.matrices import DomainMatrix
```

```
>>> A = DomainMatrix([[ZZ(1), ZZ(2)], [ZZ(3), ZZ(4)]], (2, 2), ZZ)
>>> B = DomainMatrix([[ZZ(5), ZZ(6)], [ZZ(7), ZZ(8)]], (2, 2), ZZ)
>>> A.vstack(B)
DomainMatrix([[1, 2], [3, 4], [5, 6], [7, 8]], (4, 2), ZZ)
```

```
>>> C = DomainMatrix([[ZZ(9), ZZ(10)], [ZZ(11), ZZ(12)]], (2, 2), ZZ)
>>> A.vstack(B, C)
DomainMatrix([[1, 2], [3, 4], [5, 6], [7, 8], [9, 10], [11, 12]], (6, 2), ZZ)
```

**See also:**

[unify](#) (page 2688)

**classmethod zeros(shape, domain, \*, fmt='sparse')**

Returns a zero DomainMatrix of size shape, belonging to the specified domain

**Examples**

```
>>> from sympy.polys.matrices import DomainMatrix
>>> from sympy import QQ
>>> DomainMatrix.zeros((2, 3), QQ)
DomainMatrix({}, (2, 3), QQ)
```

## DDM Class Reference

**class** `sympy.polys.matrices.ddm.DDM(rowlist, shape, domain)`

Dense matrix based on polys domain elements

This is a list subclass and is a wrapper for a list of lists that supports basic matrix arithmetic  $+$ ,  $-$ ,  $*$ .

**add**(*b*)

$a + b$

**charpoly**()

Coefficients of characteristic polynomial of *a*

**det**()

Determinant of *a*

**hstack**(\**B*)

Horizontally stacks [DDM](#) (page 2690) matrices.

### Examples

```
>>> from sympy import ZZ
>>> from sympy.polys.matrices.sdm import DDM
```

```
>>> A = DDM([[ZZ(1), ZZ(2)], [ZZ(3), ZZ(4)]], (2, 2), ZZ)
>>> B = DDM([[ZZ(5), ZZ(6)], [ZZ(7), ZZ(8)]], (2, 2), ZZ)
>>> A.hstack(B)
[[1, 2, 5, 6], [3, 4, 7, 8]]
```

```
>>> C = DDM([[ZZ(9), ZZ(10)], [ZZ(11), ZZ(12)]], (2, 2), ZZ)
>>> A.hstack(B, C)
[[1, 2, 5, 6, 9, 10], [3, 4, 7, 8, 11, 12]]
```

**inv**()

Inverse of *a*

**is\_lower**()

Says whether this matrix is lower-triangular. True can be returned even if the matrix is not square.

**is\_upper**()

Says whether this matrix is upper-triangular. True can be returned even if the matrix is not square.

**is\_zero\_matrix**()

Says whether this matrix has all zero entries.

**lu**()

L, U decomposition of *a*

**lu\_solve**(*b*)

*x* where  $a*x = b$

**matmul(*b*)***a* @ *b* (matrix product)**neg()**-*a***rref()**Reduced-row echelon form of *a* and list of pivots**scc()**Strongly connected components of a square matrix *a*.

### Examples

```
>>> from sympy import ZZ
>>> from sympy.polys.matrices.sdm import DDM
>>> A = DDM([[ZZ(1), ZZ(0)], [ZZ(0), ZZ(1)]], (2, 2), ZZ)
>>> A.scc()
[[0], [1]]
```

#### See also:

[\*sympy.polys.matrices.domainmatrix.DomainMatrix.scc\*](#) (page 2684)**sub(*b*)***a* - *b***vstack(\**B*)**Vertically stacks [\*DDM\*](#) (page 2690) matrices.

### Examples

```
>>> from sympy import ZZ
>>> from sympy.polys.matrices.sdm import DDM
```

```
>>> A = DDM([[ZZ(1), ZZ(2)], [ZZ(3), ZZ(4)]], (2, 2), ZZ)
>>> B = DDM([[ZZ(5), ZZ(6)], [ZZ(7), ZZ(8)]], (2, 2), ZZ)
>>> A.vstack(B)
[[1, 2], [3, 4], [5, 6], [7, 8]]
```

```
>>> C = DDM([[ZZ(9), ZZ(10)], [ZZ(11), ZZ(12)]], (2, 2), ZZ)
>>> A.vstack(B, C)
[[1, 2], [3, 4], [5, 6], [7, 8], [9, 10], [11, 12]]
```

## SDM Class Reference

**class** sympy.polys.matrices.sdm.**SDM**(elemsdict, shape, domain)

Sparse matrix based on polys domain elements

This is a dict subclass and is a wrapper for a dict of dicts that supports basic matrix arithmetic  $+$ ,  $-$ ,  $*$ .

In order to create a new [SDM](#) (page 2692), a dict of dicts mapping non-zero elements to their corresponding row and column in the matrix is needed.

We also need to specify the shape and [Domain](#) (page 2504) of our [SDM](#) (page 2692) object.

We declare a 2x2 [SDM](#) (page 2692) matrix belonging to QQ domain as shown below. The 2x2 Matrix in the example is

$$A = \begin{bmatrix} 0 & \frac{1}{2} \\ 0 & 0 \end{bmatrix}$$

```
>>> from sympy.polys.matrices.sdm import SDM
>>> from sympy import QQ
>>> elemsdict = {0:{1:QQ(1, 2)}}
>>> A = SDM(elemsdict, (2, 2), QQ)
>>> A
{0: {1: 1/2}}
```

We can manipulate [SDM](#) (page 2692) the same way as a Matrix class

```
>>> from sympy import ZZ
>>> A = SDM({0:{1: ZZ(2)}}, 1:{0:ZZ(1)}}, (2, 2), ZZ)
>>> B = SDM({0:{0: ZZ(3)}}, 1:{1:ZZ(4)}}, (2, 2), ZZ)
>>> A + B
{0: {0: 3, 1: 2}, 1: {0: 1, 1: 4}}
```

Multiplication

```
>>> A*B
{0: {1: 8}, 1: {0: 3}}
>>> A*ZZ(2)
{0: {1: 4}, 1: {0: 2}}
```

**add(B)**

Adds two [SDM](#) (page 2692) matrices

### Examples

```
>>> from sympy import ZZ
>>> from sympy.polys.matrices.sdm import SDM
>>> A = SDM({0:{1: ZZ(2)}}, 1:{0:ZZ(1)}}, (2, 2), ZZ)
>>> B = SDM({0:{0: ZZ(3)}}, 1:{1:ZZ(4)}}, (2, 2), ZZ)
>>> A.add(B)
{0: {0: 3, 1: 2}, 1: {0: 1, 1: 4}}
```

**charpoly()**

Returns the coefficients of the characteristic polynomial of the *SDM* (page 2692) matrix. These elements will be domain elements. The domain of the elements will be same as domain of the *SDM* (page 2692).

**Examples**

```
>>> from sympy import QQ, Symbol
>>> from sympy.polys.matrices.sdm import SDM
>>> from sympy.polys import Poly
>>> A = SDM({0:{0:QQ(1), 1:QQ(2)}, 1:{0:QQ(3), 1:QQ(4)}}), (2, 2), QQ)
>>> A.charpoly()
[1, -5, -2]
```

We can create a polynomial using the coefficients using *Poly* (page 2378)

```
>>> x = Symbol('x')
>>> p = Poly(A.charpoly(), x, domain=A.domain)
>>> p
Poly(x**2 - 5*x - 2, x, domain='QQ')
```

**convert\_to(K)**

Converts the *Domain* (page 2504) of a *SDM* (page 2692) matrix to K

**Examples**

```
>>> from sympy import ZZ, QQ
>>> from sympy.polys.matrices.sdm import SDM
>>> A = SDM({0:{1: ZZ(2)}, 1:{0:ZZ(1)}}), (2, 2), ZZ)
>>> A.convert_to(QQ)
{0: {1: 2}, 1: {0: 1}}
```

**copy()**

Returns the copy of a *SDM* (page 2692) object

**Examples**

```
>>> from sympy.polys.matrices.sdm import SDM
>>> from sympy import QQ
>>> elemsdict = {0:{1:QQ(2)}, 1:{}}
>>> A = SDM(elemsdict, (2, 2), QQ)
>>> B = A.copy()
>>> B
{0: {1: 2}, 1: {}}
```

**det()**

Returns determinant of A

### Examples

```
>>> from sympy import QQ
>>> from sympy.polys.matrices.sdm import SDM
>>> A = SDM({0:{0:QQ(1), 1:QQ(2)}, 1:{0:QQ(3), 1:QQ(4)}}), (2, 2), QQ)
>>> A.det()
-2
```

**classmethod** `eye(shape, domain)`

Returns a identity *SDM* (page 2692) matrix of dimensions size x size, belonging to the specified domain

### Examples

```
>>> from sympy.polys.matrices.sdm import SDM
>>> from sympy import QQ
>>> I = SDM.eye((2, 2), QQ)
>>> I
{0: {0: 1}, 1: {1: 1}}
```

**classmethod** `from_ddm(ddm)`

converts object of *DDM* (page 2690) to *SDM* (page 2692)

### Examples

```
>>> from sympy.polys.matrices.ddm import DDM
>>> from sympy.polys.matrices.sdm import SDM
>>> from sympy import QQ
>>> ddm = DDM([[QQ(1, 2), 0], [0, QQ(3, 4)]], (2, 2), QQ)
>>> A = SDM.from_ddm(ddm)
>>> A
{0: {0: 1/2}, 1: {1: 3/4}}
```

**classmethod** `from_list(ddm, shape, domain)`

#### Parameters

**ddm:**

list of lists containing domain elements

**shape:**

Dimensions of *SDM* (page 2692) matrix

**domain:**

Represents *Domain* (page 2504) of *SDM* (page 2692) object

#### Returns

*SDM* (page 2692) containing elements of ddm

## Examples

```
>>> from sympy.polys.matrices.sdm import SDM
>>> from sympy import QQ
>>> ddm = [[QQ(1, 2), QQ(0)], [QQ(0), QQ(3, 4)]]
>>> A = SDM.from_list(ddm, (2, 2), QQ)
>>> A
{0: {0: 1/2}, 1: {1: 3/4}}
```

### hstack(\*B)

Horizontally stacks *SDM* (page 2692) matrices.

## Examples

```
>>> from sympy import ZZ
>>> from sympy.polys.matrices.sdm import SDM
```

```
>>> A = SDM({0: {0: ZZ(1), 1: ZZ(2)}, 1: {0: ZZ(3), 1: ZZ(4)}}), (2, 2), ZZ)
>>> B = SDM({0: {0: ZZ(5), 1: ZZ(6)}, 1: {0: ZZ(7), 1: ZZ(8)}}), (2, 2), ZZ)
>>> A.hstack(B)
{0: {0: 1, 1: 2, 2: 5, 3: 6}, 1: {0: 3, 1: 4, 2: 7, 3: 8}}
```

```
>>> C = SDM({0: {0: ZZ(9), 1: ZZ(10)}, 1: {0: ZZ(11), 1: ZZ(12)}}), (2, 2), ZZ)
>>> A.hstack(B, C)
{0: {0: 1, 1: 2, 2: 5, 3: 6, 4: 9, 5: 10}, 1: {0: 3, 1: 4, 2: 7, 3: 8, 4: 11, 5: 12}}
```

### inv()

Returns inverse of a matrix A

## Examples

```
>>> from sympy import QQ
>>> from sympy.polys.matrices.sdm import SDM
>>> A = SDM({0: {0: QQ(1), 1: QQ(2)}, 1: {0: QQ(3), 1: QQ(4)}}), (2, 2), QQ)
>>> A.inv()
{0: {0: -2, 1: 1}, 1: {0: 3/2, 1: -1/2}}
```

### is\_lower()

Says whether this matrix is lower-triangular. True can be returned even if the matrix is not square.

### is\_upper()

Says whether this matrix is upper-triangular. True can be returned even if the matrix is not square.

**is\_zero\_matrix()**

Says whether this matrix has all zero entries.

**lu()**

Returns LU decomposition for a matrix A

### Examples

```
>>> from sympy import QQ
>>> from sympy.polys.matrices.sdm import SDM
>>> A = SDM({0:{0:QQ(1), 1:QQ(2)}, 1:{0:QQ(3), 1:QQ(4)}}), (2, 2), QQ)
>>> A.lu()
({0: {0: 1}, 1: {0: 3, 1: 1}}, {0: {0: 1, 1: 2}, 1: {1: -2}}, [])
```

**lu\_solve(b)**Uses LU decomposition to solve  $Ax = b$ ,

### Examples

```
>>> from sympy import QQ
>>> from sympy.polys.matrices.sdm import SDM
>>> A = SDM({0:{0:QQ(1), 1:QQ(2)}, 1:{0:QQ(3), 1:QQ(4)}}), (2, 2), QQ)
>>> b = SDM({0:{0:QQ(1)}, 1:{0:QQ(2)}}), (2, 1), QQ)
>>> A.lu_solve(b)
{1: {0: 1/2}}
```

**matmul(B)**

Performs matrix multiplication of two SDM matrices

**Parameters****A, B: SDM to multiply****Returns**

SDM

SDM after multiplication

**Raises****DomainError**

If domain of A does not match with that of B

### Examples

```
>>> from sympy import ZZ
>>> from sympy.polys.matrices.sdm import SDM
>>> A = SDM({0:{1: ZZ(2)}, 1:{0:ZZ(1)}}), (2, 2), ZZ)
>>> B = SDM({0:{0:ZZ(2), 1:ZZ(3)}, 1:{0:ZZ(4)}}), (2, 2), ZZ)
>>> A.matmul(B)
{0: {0: 8}, 1: {0: 2, 1: 3}}
```

**mul(b)**

Multiplies each element of A with a scalar b

**Examples**

```
>>> from sympy import ZZ
>>> from sympy.polys.matrices.sdm import SDM
>>> A = SDM({0:{1: ZZ(2)}, 1:{0:ZZ(1)}} , (2, 2), ZZ)
>>> A.mul(ZZ(3))
{0: {1: 6}, 1: {0: 3}}
```

**neg()**Returns the negative of a *SDM* (page 2692) matrix**Examples**

```
>>> from sympy import ZZ
>>> from sympy.polys.matrices.sdm import SDM
>>> A = SDM({0:{1: ZZ(2)}, 1:{0:ZZ(1)}} , (2, 2), ZZ)
>>> A.neg()
{0: {1: -2}, 1: {0: -1}}
```

**classmethod new(sdm, shape, domain)****Parameters****sdm:** A dict of dicts for non-zero elements in SDM**shape:** tuple representing dimension of SDM**domain:** Represents :py:class:`~.Domain` of SDM**Returns**An *SDM* (page 2692) object**Examples**

```
>>> from sympy.polys.matrices.sdm import SDM
>>> from sympy import QQ
>>> elemsdict = {0:{1: QQ(2)}}
>>> A = SDM.new(elemsdict, (2, 2), QQ)
>>> A
{0: {1: 2}}
```

**nullspace()**Returns nullspace for a *SDM* (page 2692) matrix A

### Examples

```
>>> from sympy import QQ
>>> from sympy.polys.matrices.sdm import SDM
>>> A = SDM({0:{0:QQ(1), 1:QQ(2)}, 1:{0:QQ(2), 1:QQ(4)}}), (2, 2), QQ)
>>> A.nullspace()
({0: {0: -2, 1: 1}}, [1])
```

### rref()

Returns reduced-row echelon form and list of pivots for the [SDM](#) (page 2692)

### Examples

```
>>> from sympy import QQ
>>> from sympy.polys.matrices.sdm import SDM
>>> A = SDM({0:{0:QQ(1), 1:QQ(2)}, 1:{0:QQ(2), 1:QQ(4)}}), (2, 2), QQ)
>>> A.rref()
({0: {0: 1, 1: 2}}, [0])
```

### scc()

Strongly connected components of a square matrix A.

### Examples

```
>>> from sympy import ZZ
>>> from sympy.polys.matrices.sdm import SDM
>>> A = SDM({0:{0:ZZ(2)}, 1:{1:ZZ(1)}}), (2, 2), ZZ)
>>> A.scc()
[[0], [1]]
```

### See also:

[sympy.polys.matrices.domainmatrix.DomainMatrix.scc](#) (page 2684)

### sub(B)

Subtracts two [SDM](#) (page 2692) matrices

### Examples

```
>>> from sympy import ZZ
>>> from sympy.polys.matrices.sdm import SDM
>>> A = SDM({0:{1:ZZ(2)}, 1:{0:ZZ(1)}}), (2, 2), ZZ)
>>> B = SDM({0:{0:ZZ(3)}, 1:{1:ZZ(4)}}), (2, 2), ZZ)
>>> A.sub(B)
{0: {0: -3, 1: 2}, 1: {0: 1, 1: -4}}
```

### to\_ddm()

Convert a [SDM](#) (page 2692) object to a [DDM](#) (page 2690) object

## Examples

```
>>> from sympy.polys.matrices.sdm import SDM
>>> from sympy import QQ
>>> A = SDM({0:{1:QQ(2)}}, 1:{}}, (2, 2), QQ)
>>> A.to_ddm()
[[0, 2], [0, 0]]
```

### to\_list()

Converts a *SDM* (page 2692) object to a list

## Examples

```
>>> from sympy.polys.matrices.sdm import SDM
>>> from sympy import QQ
>>> elemsdict = {0:{1:QQ(2)}}, 1:{}}
>>> A = SDM(elemsdict, (2, 2), QQ)
>>> A.to_list()
[[0, 2], [0, 0]]
```

### transpose()

Returns the transpose of a *SDM* (page 2692) matrix

## Examples

```
>>> from sympy.polys.matrices.sdm import SDM
>>> from sympy import QQ
>>> A = SDM({0:{1:QQ(2)}}, 1:{}}, (2, 2), QQ)
>>> A.transpose()
{1: {0: 2}}
```

### vstack(\*B)

Vertically stacks *SDM* (page 2692) matrices.

## Examples

```
>>> from sympy import ZZ
>>> from sympy.polys.matrices.sdm import SDM

>>> A = SDM({0: {0: ZZ(1), 1: ZZ(2)}, 1: {0: ZZ(3), 1: ZZ(4)}}), (2, 2), ZZ)
>>> B = SDM({0: {0: ZZ(5), 1: ZZ(6)}, 1: {0: ZZ(7), 1: ZZ(8)}}), (2, 2), ZZ)
>>> A.vstack(B)
{0: {0: 1, 1: 2}, 1: {0: 3, 1: 4}, 2: {0: 5, 1: 6}, 3: {0: 7, 1: 8}}
```

```
>>> C = SDM({0: {0: ZZ(9), 1: ZZ(10)}, 1: {0: ZZ(11), 1: ZZ(12)}}), (2,
↳ 2), ZZ)
>>> A.vstack(B, C)
{0: {0: 1, 1: 2}, 1: {0: 3, 1: 4}, 2: {0: 5, 1: 6}, 3: {0: 7, 1: 8},
↳ 4: {0: 9, 1: 10}, 5: {0: 11, 1: 12}}
```

**classmethod zeros**(*shape, domain*)

Returns a [SDM](#) (page 2692) of size *shape*, belonging to the specified domain

In the example below we declare a matrix A where,

$$A := \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix}$$

```
>>> from sympy.polys.matrices.sdm import SDM
>>> from sympy import QQ
>>> A = SDM.zeros((2, 3), QQ)
>>> A
{}

```

## Normal Forms

`sympy.polys.matrices.normalforms.smith_normal_form(m)`

Return the Smith Normal Form of a matrix *m* over the ring *domain*. This will only work if the ring is a principal ideal domain.

## Examples

```
>>> from sympy import ZZ
>>> from sympy.polys.matrices import DomainMatrix
>>> from sympy.polys.matrices.normalforms import smith_normal_form
>>> m = DomainMatrix([[ZZ(12), ZZ(6), ZZ(4)],
... [ZZ(3), ZZ(9), ZZ(6)],
... [ZZ(2), ZZ(16), ZZ(14)]]), (3, 3), ZZ)
>>> print(smith_normal_form(m).to_Matrix())
Matrix([[1, 0, 0], [0, 10, 0], [0, 0, -30]])

```

`sympy.polys.matrices.normalforms.hermite_normal_form(A, *, D=None,  
check_rank=False)`

Compute the Hermite Normal Form of [DomainMatrix](#) (page 2671) *A* over [ZZ](#) (page 2525).

### Parameters

**A** :  $m \times n$  [DomainMatrix](#) over [ZZ](#) (page 2525).

**D** : [ZZ](#) (page 2525), optional

Let *W* be the HNF of *A*. If known in advance, a positive integer *D* being any multiple of  $\det(W)$  may be provided. In this case, if *A* also has rank *m*, then we may use an alternative algorithm that works mod *D* in order to prevent coefficient explosion.

**check\_rank** : boolean, optional (default=False)

The basic assumption is that, if you pass a value for  $D$ , then you already believe that  $A$  has rank  $m$ , so we do not waste time checking it for you. If you do want this to be checked (and the ordinary, non-modulo  $D$  algorithm to be used if the check fails), then set `check_rank` to `True`.

### Returns

[`DomainMatrix`](#) (page 2671)

The HNF of matrix  $A$ .

### Raises

#### **DMDomainError**

If the domain of the matrix is not [`ZZ`](#) (page 2525), or if  $D$  is given but is not in [`ZZ`](#) (page 2525).

#### **DMShapeError**

If the mod  $D$  algorithm is used but the matrix has more rows than columns.

### Examples

```
>>> from sympy import ZZ
>>> from sympy.polys.matrices import DomainMatrix
>>> from sympy.polys.matrices.normalforms import hermite_normal_form
>>> m = DomainMatrix([[ZZ(12), ZZ(6), ZZ(4)],
... [ZZ(3), ZZ(9), ZZ(6)],
... [ZZ(2), ZZ(16), ZZ(14)]]), (3, 3), ZZ)
>>> print(hermite_normal_form(m).to_Matrix())
Matrix([[10, 0, 2], [0, 15, 3], [0, 0, 2]])
```

## Number Fields

### Introduction

Like many other computations in algebraic number theory, the splitting of rational primes can be treated by *rational* methods only. This fact is very important if computation by automatic computing machinery is considered. Only the knowledge of the irreducible polynomial  $f(x)$ , a zero of which generates the field in question, is needed.

—Olga Taussky, 1953

Concepts like number fields and algebraic numbers are essential to our understanding of algebraic number theory, but to the computer the subject is all about polynomials: the ring  $\mathbb{Q}[x]$  reduced modulo irreducible polynomials  $f(x) \in \mathbb{Q}[x]$ . It thus finds a natural home under the [`polys`](#) (page 2360) module in SymPy.

Various authors (such as Taussky, Zimmer, Pohst and Zassenhaus, or Cohen) have articulated the main goals of computational algebraic number theory in different ways, but invariably the list centers around a certain essential set of tasks. As a goal for the `numberfields` module in SymPy, we may set the following list, based on [Cohen93], Sec. 4.9.3.

For a number field  $K = \mathbb{Q}(\theta)$ , whose ring of algebraic integers is denoted  $\mathbb{Z}_K$ , compute:

1. an integral basis of  $\mathbb{Z}_K$
2. the decomposition of rational primes in  $\mathbb{Z}_K$
3.  $p$ -adic valuations for ideals and elements
4. the Galois group of the Galois closure of  $K$
5. a system of fundamental units of  $K$
6. the regulator  $R(K)$
7. the class number
8. the structure of the class group  $Cl(K)$
9. decide whether a given ideal is principal, and if so compute a generator.

As a foundation, and to support our basic ability to define and work with number fields and algebraic numbers, we also set the following problems, following [Cohen93], Sec. 4.5.

10. Given an algebraic number – expressed by radicals and rational operations, or even as a special value of a transcendental function – determine its minimal polynomial over  $\mathbb{Q}$ .
11. The Subfield Problem: Given two number fields  $\mathbb{Q}(\alpha)$ ,  $\mathbb{Q}(\beta)$  via the minimal polynomials for their generators  $\alpha$  and  $\beta$ , decide whether one field is isomorphic to a subfield of the other, and if so exhibit an embedding.
12. The Field Membership Problem: Given two algebraic numbers  $\alpha$ ,  $\beta$ , decide whether  $\alpha \in \mathbb{Q}(\beta)$ , and if so write  $\alpha = f(\beta)$  for some  $f(x) \in \mathbb{Q}[x]$ .
13. The Primitive Element Problem: Given several algebraic numbers  $\alpha_1, \dots, \alpha_m$ , compute a single algebraic number  $\theta$  such that  $\mathbb{Q}(\alpha_1, \dots, \alpha_m) = \mathbb{Q}(\theta)$ .

At present only a subset of the tasks enumerated above is yet supported in SymPy, and if you are interested in expanding support, you are encouraged to contribute! An excellent source, providing solutions to all the remaining problems (as well as those already solved) is [Cohen93].

At time of writing, the existing solutions to the above problems are found in the following places:

| Task                         | Implementation                                                |
|------------------------------|---------------------------------------------------------------|
| (1) integral basis           | <a href="#"><code>round_two()</code></a> (page 2703)          |
| (2) prime decomposition      | <a href="#"><code>prime_decomp()</code></a> (page 2705)       |
| (3) p-adic valuation         | <a href="#"><code>prime_valuation()</code></a> (page 2709)    |
| (10) find minimal polynomial | <a href="#"><code>minimal_polynomial()</code></a> (page 2710) |
| (11) subfield                | <a href="#"><code>field_isomorphism()</code></a> (page 2711)  |
| (12) field membership        | <a href="#"><code>to_number_field()</code></a> (page 2714)    |
| (13) primitive element       | <a href="#"><code>primitive_element()</code></a> (page 2712)  |

## Solving the Main Problems

### Integral Basis

`sympy.polys.numberfields.basis.round_two(T, radicals=None)`

Zassenhaus’s “Round 2” algorithm.

#### Parameters

**T** : [\*Poly\*](#) (page 2378), [\*AlgebraicField\*](#) (page 2539)

Either (1) the irreducible monic polynomial over [\*ZZ\*](#) (page 2525) defining the number field, or (2) an [\*AlgebraicField\*](#) (page 2539) representing the number field itself.

**radicals** : dict, optional

This is a way for any  $p$ -radicals (if computed) to be returned by reference. If desired, pass an empty dictionary. If the algorithm reaches the point where it computes the nilradical mod  $p$  of the ring of integers  $Z_K$ , then an  $\mathbb{F}_p$ -basis for this ideal will be stored in this dictionary under the key  $p$ . This can be useful for other algorithms, such as prime decomposition.

#### Returns

Pair (ZK, dK), where:

ZK is a [\*Submodule\*](#) (page 2726) representing the maximal order.

dK is the discriminant of the field  $K = \mathbb{Q}[x]/(T(x))$ .

## Explanation

Carry out Zassenhaus's "Round 2" algorithm on a monic irreducible polynomial  $T$  over  $\mathbb{Z}$  (page 2525). This computes an integral basis and the discriminant for the field  $K = \mathbb{Q}[x]/(T(x))$ .

Alternatively, you may pass an *AlgebraicField* (page 2539) instance, in place of the polynomial  $T$ , in which case the algorithm is applied to the minimal polynomial for the field's primitive element.

Ordinarily this function need not be called directly, as one can instead access the *maximal\_order()* (page 2545), *integral\_basis()* (page 2544), and *discriminant()* (page 2543) methods of an *AlgebraicField* (page 2539).

## Examples

Working through an *AlgebraicField*:

```
>>> from sympy import Poly, QQ
>>> from sympy.abc import x
>>> T = Poly(x ** 3 + x ** 2 - 2 * x + 8)
>>> K = QQ.alg_field_from_poly(T, "theta")
>>> print(K.maximal_order())
Submodule[[2, 0, 0], [0, 2, 0], [0, 1, 1]]/2
>>> print(K.discriminant())
-503
>>> print(K.integral_basis(fmt='sympy'))
[1, theta, theta/2 + theta**2/2]
```

Calling directly:

```
>>> from sympy import Poly
>>> from sympy.abc import x
>>> from sympy.polys.numberfields.basis import round_two
>>> T = Poly(x ** 3 + x ** 2 - 2 * x + 8)
>>> print(round_two(T))
(Submodule[[2, 0, 0], [0, 2, 0], [0, 1, 1]]/2, -503)
```

The nilradicals mod  $p$  that are sometimes computed during the Round Two algorithm may be useful in further calculations. Pass a dictionary under *radicals* to receive these:

```
>>> T = Poly(x**3 + 3*x**2 + 5)
>>> rad = {}
>>> ZK, dK = round_two(T, radicals=rad)
>>> print(rad)
{3: Submodule[[-1, 1, 0], [-1, 0, 1]]}
```

## Prime Decomposition

`sympy.polys.numberfields.primes.prime_decomp(p, T=None, ZK=None, dK=None, radical=None)`

Compute the decomposition of rational prime  $p$  in a number field.

### Parameters

**p** : int

The rational prime whose decomposition is desired.

**T** : *Poly* (page 2378), optional

Monic irreducible polynomial defining the number field  $K$  in which to factor. NOTE: at least one of  $T$  or  $ZK$  must be provided.

**ZK** : *Submodule* (page 2726), optional

The maximal order for  $K$ , if already known. NOTE: at least one of  $T$  or  $ZK$  must be provided.

**dK** : int, optional

The discriminant of the field  $K$ , if already known.

**radical** : *Submodule* (page 2726), optional

The nilradical mod  $p$  in the integers of  $K$ , if already known.

### Returns

List of *PrimeIdeal* (page 2706) instances.

## Explanation

Ordinarily this should be accessed through the *primes\_above()* (page 2545) method of an *AlgebraicField* (page 2539).

## Examples

```
>>> from sympy import Poly, QQ
>>> from sympy.abc import x, theta
>>> T = Poly(x**3 + x**2 - 2*x + 8)
>>> K = QQ.algebraic_field((T, theta))
>>> print(K.primes_above(2))
[[(2, x**2 + 1) e=1, f=1], [(2, (x**2 + 3*x + 2)/2) e=1, f=1],
 [(2, (3*x**2 + 3*x)/2) e=1, f=1]]
```

## References

[R714]

**class** sympy.polys.numberfields.primes.**PrimeIdeal**(*ZK, p, alpha, f, e=None*)

A prime ideal in a ring of algebraic integers.

**\_\_init\_\_**(*ZK, p, alpha, f, e=None*)

### Parameters

**ZK** : [Submodule](#) (page 2726)

The maximal order where this ideal lives.

**p** : int

The rational prime this ideal divides.

**alpha** : [PowerBasisElement](#) (page 2732)

Such that the ideal is equal to  $p \cdot \text{ZK} + \alpha \cdot \text{ZK}$ .

**f** : int

The inertia degree.

**e** : int, None, optional

The ramification index, if already known. If None, we will compute it here.

**\_\_add\_\_**(*other*)

Convert to a [Submodule](#) (page 2726) and add to another [Submodule](#) (page 2726).

**See also:**

[as\\_submodule](#) (page 2706)

**\_\_mul\_\_**(*other*)

Convert to a [Submodule](#) (page 2726) and multiply by another [Submodule](#) (page 2726) or a rational number.

**See also:**

[as\\_submodule](#) (page 2706)

**as\_submodule**()

Represent this prime ideal as a [Submodule](#) (page 2726).

### Returns

[Submodule](#) (page 2726)

Will be equal to  $\text{self.p} * \text{self.ZK} + \text{self.alpha} * \text{self.ZK}$ .

## Explanation

The *PrimeIdeal* (page 2706) class serves to bundle information about a prime ideal, such as its inertia degree, ramification index, and two-generator representation, as well as to offer helpful methods like *valuation()* (page 2709) and *test\_factor()* (page 2709).

However, in order to be added and multiplied by other ideals or rational numbers, it must first be converted into a *Submodule* (page 2726), which is a class that supports these operations.

In many cases, the user need not perform this conversion deliberately, since it is automatically performed by the arithmetic operator methods *\_\_add\_\_()* (page 2706) and *\_\_mul\_\_()* (page 2706).

Raising a *PrimeIdeal* (page 2706) to a non-negative integer power is also supported.

## Examples

```
>>> from sympy import Poly, cyclotomic_poly, prime_decomp
>>> T = Poly(cyclotomic_poly(7))
>>> P0 = prime_decomp(7, T)[0]
>>> print(P0**6 == 7*P0.ZK)
True
```

Note that, on both sides of the equation above, we had a *Submodule* (page 2726). In the next equation we recall that adding ideals yields their GCD. This time, we need a deliberate conversion to *Submodule* (page 2726) on the right:

```
>>> print(P0 + 7*P0.ZK == P0.as_submodule())
True
```

### See also:

*\_\_add\_\_* (page 2706), *\_\_mul\_\_* (page 2706)

### property *is\_inert*

Say whether the rational prime we divide is inert, i.e. stays prime in our ring of integers.

### *reduce\_ANP(a)*

Reduce an *ANP* (page 2568) to a “small representative” modulo this prime ideal.

#### Parameters

**elt** : *ANP* (page 2568)

The element to be reduced.

#### Returns

*ANP* (page 2568)

The reduced element.

### See also:

*reduce\_element* (page 2708), *reduce\_alg\_num* (page 2707), *Submodule.reduce\_element* (page 2728)

**reduce\_alg\_num(*a*)**

Reduce an [AlgebraicNumber](#) (page 988) to a “small representative” modulo this prime ideal.

**Parameters**

**elt** : [AlgebraicNumber](#) (page 988)

The element to be reduced.

**Returns**

[AlgebraicNumber](#) (page 988)

The reduced element.

**See also:**

[reduce\\_element](#) (page 2708), [reduce\\_ANP](#) (page 2707), [Submodule.reduce\\_element](#) (page 2728)

**reduce\_element(*elt*)**

Reduce a [PowerBasisElement](#) (page 2732) to a “small representative” modulo this prime ideal.

**Parameters**

**elt** : [PowerBasisElement](#) (page 2732)

The element to be reduced.

**Returns**

[PowerBasisElement](#) (page 2732)

The reduced element.

**See also:**

[reduce\\_ANP](#) (page 2707), [reduce\\_alg\\_num](#) (page 2707), [Submodule.reduce\\_element](#) (page 2728)

**repr(*field\_gen=None, just\_gens=False*)**

Print a representation of this prime ideal.

**Parameters**

**field\_gen** : [Symbol](#) (page 976), None, optional (default=None)

The symbol to use for the generator of the field. This will appear in our representation of `self.alpha`. If None, we use the variable of the defining polynomial of `self.ZK`.

**just\_gens** : bool, optional (default=False)

If True, just print the “(p, alpha)” part, showing “just the generators” of the prime ideal. Otherwise, print a string of the form “[ (p, alpha) e=..., f=... ]”, giving the ramification index and inertia degree, along with the generators.

## Examples

```
>>> from sympy import cyclotomic_poly, QQ
>>> from sympy.abc import x, zeta
>>> T = cyclotomic_poly(7, x)
>>> K = QQ.algebraic_field((T, zeta))
>>> P = K.primes_above(11)
>>> print(P[0].repr())
[(11, x**3 + 5*x**2 + 4*x - 1) e=1, f=3]
>>> print(P[0].repr(field_gen=zeta))
[(11, zeta**3 + 5*zeta**2 + 4*zeta - 1) e=1, f=3]
>>> print(P[0].repr(field_gen=zeta, just_gens=True))
(11, zeta**3 + 5*zeta**2 + 4*zeta - 1)
```

### test\_factor()

Compute a test factor for this prime ideal.

## Explanation

Write  $\mathfrak{p}$  for this prime ideal,  $p$  for the rational prime it divides. Then, for computing  $p$ -adic valuations it is useful to have a number  $\beta \in \mathbb{Z}_K$  such that  $p/\mathfrak{p} = p\mathbb{Z}_K + \beta\mathbb{Z}_K$ .

Essentially, this is the same as the number  $\Psi$  (or the “reagent”) from Kummer’s 1847 paper (*Ueber die Zerlegung...*, Crelle vol. 35) in which ideal divisors were invented.

### valuation(I)

Compute the  $p$ -adic valuation of integral ideal  $I$  at this prime ideal.

#### Parameters

**I** : *Submodule* (page 2726)

#### See also:

*prime\_valuation* (page 2709)

## p-adic Valuation

`sympy.polys.numberfields.primes.prime_valuation(I, P)`

Compute the  $P$ -adic valuation for an integral ideal  $I$ .

#### Parameters

**I** : *Submodule* (page 2726)

An integral ideal whose valuation is desired.

**P** : *PrimeIdeal* (page 2706)

The prime at which to compute the valuation.

#### Returns

int

## Examples

```
>>> from sympy import QQ
>>> from sympy.polys.numberfields import prime_valuation
>>> K = QQ.cyclotomic_field(5)
>>> P = K.primes_above(5)
>>> ZK = K.maximal_order()
>>> print(prime_valuation(25*ZK, P[0]))
8
```

## Finding Minimal Polynomials

`sympy.polys.numberfields.minpoly.minimal_polynomial(ex, x=None, compose=True,  
 polys=False, domain=None)`

Computes the minimal polynomial of an algebraic element.

### Parameters

**ex** : Expr

Element or expression whose minimal polynomial is to be calculated.

**x** : Symbol, optional

Independent variable of the minimal polynomial

**compose** : boolean, optional (default=True)

Method to use for computing minimal polynomial. If `compose=True` (default) then `_minpoly_compose` is used, if `compose=False` then groebner bases are used.

**polys** : boolean, optional (default=False)

If True returns a Poly object else an Expr object.

**domain** : Domain, optional

Ground domain

## Notes

By default `compose=True`, the minimal polynomial of the subexpressions of `ex` are computed, then the arithmetic operations on them are performed using the resultant and factorization. If `compose=False`, a bottom-up algorithm is used with `groebner`. The default algorithm stalls less frequently.

If no ground domain is given, it will be generated automatically from the expression.

## Examples

```
>>> from sympy import minimal_polynomial, sqrt, solve, QQ
>>> from sympy.abc import x, y

>>> minimal_polynomial(sqrt(2), x)
x**2 - 2
>>> minimal_polynomial(sqrt(2), x, domain=QQ.algebraic_field(sqrt(2)))
x - sqrt(2)
>>> minimal_polynomial(sqrt(2) + sqrt(3), x)
x**4 - 10*x**2 + 1
>>> minimal_polynomial(solve(x**3 + x + 3)[0], x)
x**3 + x + 3
>>> minimal_polynomial(sqrt(y), x)
x**2 - y
```

`sympy.polys.numberfields.minpoly.minpoly(ex, x=None, compose=True, polys=False, domain=None)`

This is a synonym for [`minimal\_polynomial\(\)`](#) (page 2710).

## The Subfield Problem

Functions in `polys.numberfields.subfield` solve the “Subfield Problem” and allied problems, for algebraic number fields.

Following Cohen (see [Cohen93] Section 4.5), we can define the main problem as follows:

- **Subfield Problem:**

Given two number fields  $\mathbb{Q}(\alpha)$ ,  $\mathbb{Q}(\beta)$  via the minimal polynomials for their generators  $\alpha$  and  $\beta$ , decide whether one field is isomorphic to a subfield of the other.

From a solution to this problem flow solutions to the following problems as well:

- **Primitive Element Problem:**

Given several algebraic numbers  $\alpha_1, \dots, \alpha_m$ , compute a single algebraic number  $\theta$  such that  $\mathbb{Q}(\alpha_1, \dots, \alpha_m) = \mathbb{Q}(\theta)$ .

- **Field Isomorphism Problem:**

Decide whether two number fields  $\mathbb{Q}(\alpha)$ ,  $\mathbb{Q}(\beta)$  are isomorphic.

- **Field Membership Problem:**

Given two algebraic numbers  $\alpha$ ,  $\beta$ , decide whether  $\alpha \in \mathbb{Q}(\beta)$ , and if so write  $\alpha = f(\beta)$  for some  $f(x) \in \mathbb{Q}[x]$ .

`sympy.polys.numberfields.subfield.field_isomorphism(a, b, *, fast=True)`

Find an embedding of one number field into another.

#### Parameters

**a** : *Expr* (page 947)

Any expression representing an algebraic number.

**b** : *Expr* (page 947)

Any expression representing an algebraic number.

**fast** : boolean, optional (default=True)

If True, we first attempt a potentially faster way of computing the isomorphism, falling back on a slower method if this fails. If False, we go directly to the slower method, which is guaranteed to return a result.

#### Returns

List of rational numbers, or None

If  $\mathbb{Q}(a)$  is not isomorphic to some subfield of  $\mathbb{Q}(b)$ , then return None. Otherwise, return a list of rational numbers representing an element of  $\mathbb{Q}(b)$  to which  $a$  may be mapped, in order to define a monomorphism, i.e. an isomorphism from  $\mathbb{Q}(a)$  to some subfield of  $\mathbb{Q}(b)$ . The elements of the list are the coefficients of falling powers of  $b$ .

#### Explanation

This function looks for an isomorphism from  $\mathbb{Q}(a)$  onto some subfield of  $\mathbb{Q}(b)$ . Thus, it solves the Subfield Problem.

#### Examples

```
>>> from sympy import sqrt, field_isomorphism, I
>>> print(field_isomorphism(3, sqrt(2)))
[3]
>>> print(field_isomorphism(I*sqrt(3), I*sqrt(3)/2))
[2, 0]
```

`sympy.polys.numberfields.subfield.primitive_element(extension, x=None, *, ex=False, polys=False)`

Find a single generator for a number field given by several generators.

#### Parameters

**extension** : list of *Expr* (page 947)

Each expression must represent an algebraic number  $\alpha_i$ .

**x** : *Symbol* (page 976), optional (default=None)

The desired symbol to appear in the computed minimal polynomial for the primitive element  $\theta$ . If None, we use a dummy symbol.

**ex** : boolean, optional (default=False)

If and only if `True`, compute the representation of each  $\alpha_i$  as a  $\mathbb{Q}$ -linear combination over the powers of  $\theta$ .

**polys** : boolean, optional (default=False)

If `True`, return the minimal polynomial as a *Poly* (page 2378). Otherwise return it as an *Expr* (page 947).

### Returns

Pair (f, coeffs) or triple (f, coeffs, reps), where:

f is the minimal polynomial for the primitive element. coeffs gives the primitive element as a linear combination of the given generators. reps is present if and only if argument `ex=True` was passed, and is a list of lists of rational numbers. Each list gives the coefficients of falling powers of the primitive element, to recover one of the original, given generators.

### Explanation

The basic problem is this: Given several algebraic numbers  $\alpha_1, \alpha_2, \dots, \alpha_n$ , find a single algebraic number  $\theta$  such that  $\mathbb{Q}(\alpha_1, \alpha_2, \dots, \alpha_n) = \mathbb{Q}(\theta)$ .

This function actually guarantees that  $\theta$  will be a linear combination of the  $\alpha_i$ , with non-negative integer coefficients.

Furthermore, if desired, this function will tell you how to express each  $\alpha_i$  as a  $\mathbb{Q}$ -linear combination of the powers of  $\theta$ .

### Examples

```
>>> from sympy import primitive_element, sqrt, S, minpoly, simplify
>>> from sympy.abc import x
>>> f, lincomb, reps = primitive_element([sqrt(2), sqrt(3)], x, ex=True)
```

Then `lincomb` tells us the primitive element as a linear combination of the given generators `sqrt(2)` and `sqrt(3)`.

```
>>> print(lincomb)
[1, 1]
```

This means the primitive element is  $\sqrt{2} + \sqrt{3}$ . Meanwhile `f` is the minimal polynomial for this primitive element.

```
>>> print(f)
x**4 - 10*x**2 + 1
>>> print(minpoly(sqrt(2) + sqrt(3), x))
x**4 - 10*x**2 + 1
```

Finally, `reps` (which was returned only because we set keyword arg `ex=True`) tells us how to recover each of the generators  $\sqrt{2}$  and  $\sqrt{3}$  as  $\mathbb{Q}$ -linear combinations of the powers of the primitive element  $\sqrt{2} + \sqrt{3}$ .

```
>>> print([S(r) for r in reps[0]])
[1/2, 0, -9/2, 0]
>>> theta = sqrt(2) + sqrt(3)
>>> print(simplify(theta**3/2 - 9*theta/2))
sqrt(2)
>>> print([S(r) for r in reps[1]])
[-1/2, 0, 11/2, 0]
>>> print(simplify(-theta**3/2 + 11*theta/2))
sqrt(3)
```

`sympy.polys.numberfields.subfield.to_number_field(extension, theta=None, *,  
gen=None, alias=None)`

Express one algebraic number in the field generated by another.

#### Parameters

**extension** : *Expr* (page 947) or list of *Expr* (page 947)

Either the algebraic number that is to be expressed in the other field, or else a list of algebraic numbers, a primitive element for which is to be expressed in the other field.

**theta** : *Expr* (page 947), None, optional (default=None)

If an *Expr* (page 947) representing an algebraic number, behavior is as described under **Explanation**. If None, then this function reduces to a shorthand for calling *primitive\_element()* (page 2712) on *extension* and turning the computed primitive element into an *AlgebraicNumber* (page 988).

**gen** : *Symbol* (page 976), None, optional (default=None)

If provided, this will be used as the generator symbol for the minimal polynomial in the returned *AlgebraicNumber* (page 988).

**alias** : str, *Symbol* (page 976), None, optional (default=None)

If provided, this will be used as the alias symbol for the returned *AlgebraicNumber* (page 988).

#### Returns

*AlgebraicNumber*

Belonging to  $\mathbb{Q}(\theta)$  and equaling  $\eta$ .

#### Raises

**IsomorphismFailed**

If  $\eta \notin \mathbb{Q}(\theta)$ .

## Explanation

Given two algebraic numbers  $\eta, \theta$ , this function either expresses  $\eta$  as an element of  $\mathbb{Q}(\theta)$ , or else raises an exception if  $\eta \notin \mathbb{Q}(\theta)$ .

This function is essentially just a convenience, utilizing [field\\_isomorphism\(\)](#) (page 2711) (our solution of the Subfield Problem) to solve this, the Field Membership Problem.

As an additional convenience, this function allows you to pass a list of algebraic numbers  $\alpha_1, \alpha_2, \dots, \alpha_n$  instead of  $\eta$ . It then computes  $\eta$  for you, as a solution of the Primitive Element Problem, using [primitive\\_element\(\)](#) (page 2712) on the list of  $\alpha_i$ .

## Examples

```
>>> from sympy import sqrt, to_number_field
>>> eta = sqrt(2)
>>> theta = sqrt(2) + sqrt(3)
>>> a = to_number_field(eta, theta)
>>> print(type(a))
<class 'sympy.core.numbers.AlgebraicNumber'>
>>> a.root
sqrt(2) + sqrt(3)
>>> print(a)
sqrt(2)
>>> a.coeffs()
[1/2, 0, -9/2, 0]
```

We get an [AlgebraicNumber](#) (page 988), whose `.root` is  $\theta$ , whose value is  $\eta$ , and whose `.coeffs()` show how to write  $\eta$  as a  $\mathbb{Q}$ -linear combination in falling powers of  $\theta$ .

## Internals

### Algebraic number fields

Algebraic number fields are represented in SymPy by the [AlgebraicField](#) (page 2539) class, which is a part of [the polynomial domains system](#) (page 2504).

### Representing algebraic numbers

There are several different ways to represent algebraic numbers, and different forms may be preferable for different computational tasks. See [Cohen93], Sec. 4.2.

## As number field elements

In SymPy, there is a distinction between number and expression classes defined in the [sympy.core.numbers](#) (page 981) module on the one hand, and domains and domain elements defined in the [polys](#) (page 2360) module on the other. This is explained in more detail [here](#) (page 2477).

When it comes to algebraic numbers, the [sympy.core.numbers](#) (page 981) module offers the [AlgebraicNumber](#) (page 988) class, while the [polys](#) (page 2360) module offers the [ANP](#) (page 2568) class. This is the type of domain elements belonging to the [AlgebraicField](#) (page 2539) domain.

## As elements of finitely-generated modules

In computational algebraic number theory, finitely-generated  $\mathbb{Z}$ -modules are of central importance. For example, every [order](#) and every [ideal](#) is such a module.

In particular, the maximal order – or [ring of integers](#) – in a number field is a finitely-generated  $\mathbb{Z}$ -module, whose generators form an [integral basis](#) for the field.

Classes allowing us to represent such modules, and their elements, are provided in the [modules](#) (page 2716) module. Here, the [ModuleElement](#) (page 2729) class provides another way to represent algebraic numbers.

## Finitely-generated modules

Modules in number fields.

The classes defined here allow us to work with finitely generated, free modules, whose generators are algebraic numbers.

There is an abstract base class called [Module](#) (page 2719), which has two concrete subclasses, [PowerBasis](#) (page 2725) and [Submodule](#) (page 2726).

Every module is defined by its basis, or set of generators:

- For a [PowerBasis](#) (page 2725), the generators are the first  $n$  powers (starting with the zeroth) of an algebraic integer  $\theta$  of degree  $n$ . The [PowerBasis](#) (page 2725) is constructed by passing either the minimal polynomial of  $\theta$ , or an [AlgebraicField](#) (page 2539) having  $\theta$  as its primitive element.
- For a [Submodule](#) (page 2726), the generators are a set of  $\mathbb{Q}$ -linear combinations of the generators of another module. That other module is then the “parent” of the [Submodule](#) (page 2726). The coefficients of the  $\mathbb{Q}$ -linear combinations may be given by an integer matrix, and a positive integer denominator. Each column of the matrix defines a generator.

```
>>> from sympy.polys import Poly, cyclotomic_poly, ZZ
>>> from sympy.abc import x
>>> from sympy.polys.matrices import DomainMatrix, DM
>>> from sympy.polys.numberfields.modules import PowerBasis
>>> T = Poly(cyclotomic_poly(5, x))
>>> A = PowerBasis(T)
>>> print(A)
```

(continues on next page)

(continued from previous page)

```

PowerBasis(x**4 + x**3 + x**2 + x + 1)
>>> B = A.submodule_from_matrix(2 * DomainMatrix.eye(4, ZZ), denom=3)
>>> print(B)
Submodule[[2, 0, 0, 0], [0, 2, 0, 0], [0, 0, 2, 0], [0, 0, 0, 2]]/3
>>> print(B.parent)
PowerBasis(x**4 + x**3 + x**2 + x + 1)

```

Thus, every module is either a [PowerBasis](#) (page 2725), or a [Submodule](#) (page 2726), some ancestor of which is a [PowerBasis](#) (page 2725). (If  $S$  is a [Submodule](#) (page 2726), then its ancestors are  $S.parent$ ,  $S.parent.parent$ , and so on).

The [ModuleElement](#) (page 2729) class represents a linear combination of the generators of any module. Critically, the coefficients of this linear combination are not restricted to be integers, but may be any rational numbers. This is necessary so that any and all algebraic integers be representable, starting from the power basis in a primitive element  $\theta$  for the number field in question. For example, in a quadratic field  $\mathbb{Q}(\sqrt{d})$  where  $d \equiv 1 \pmod{4}$ , a denominator of 2 is needed.

A [ModuleElement](#) (page 2729) can be constructed from an integer column vector and a denominator:

```

>>> U = Poly(x**2 - 5)
>>> M = PowerBasis(U)
>>> e = M(DM([[1]], [1]], ZZ), denom=2)
>>> print(e)
[1, 1]/2
>>> print(e.module)
PowerBasis(x**2 - 5)

```

The [PowerBasisElement](#) (page 2732) class is a subclass of [ModuleElement](#) (page 2729) that represents elements of a [PowerBasis](#) (page 2725), and adds functionality pertinent to elements represented directly over powers of the primitive element  $\theta$ .

## Arithmetic with module elements

While a [ModuleElement](#) (page 2729) represents a linear combination over the generators of a particular module, recall that every module is either a [PowerBasis](#) (page 2725) or a descendant (along a chain of [Submodule](#) (page 2726) objects) thereof, so that in fact every [ModuleElement](#) (page 2729) represents an algebraic number in some field  $\mathbb{Q}(\theta)$ , where  $\theta$  is the defining element of some [PowerBasis](#) (page 2725). It thus makes sense to talk about the number field to which a given [ModuleElement](#) (page 2729) belongs.

This means that any two [ModuleElement](#) (page 2729) instances can be added, subtracted, multiplied, or divided, provided they belong to the same number field. Similarly, since  $\mathbb{Q}$  is a subfield of every number field, any [ModuleElement](#) (page 2729) may be added, multiplied, etc. by any rational number.

```

>>> from sympy import QQ
>>> from sympy.polys.numberfields.modules import to_col
>>> T = Poly(cyclotomic_poly(5))
>>> A = PowerBasis(T)
>>> C = A.submodule_from_matrix(3 * DomainMatrix.eye(4, ZZ))

```

(continues on next page)

(continued from previous page)

```

>>> e = A(to_col([0, 2, 0, 0]), denom=3)
>>> f = A(to_col([0, 0, 0, 7]), denom=5)
>>> g = C(to_col([1, 1, 1, 1]))
>>> e + f
[0, 10, 0, 21]/15
>>> e - f
[0, 10, 0, -21]/15
>>> e - g
[-9, -7, -9, -9]/3
>>> e + QQ(7, 10)
[21, 20, 0, 0]/30
>>> e * f
[-14, -14, -14, -14]/15
>>> e ** 2
[0, 0, 4, 0]/9
>>> f // g
[7, 7, 7, 7]/15
>>> f * QQ(2, 3)
[0, 0, 0, 14]/15

```

However, care must be taken with arithmetic operations on *ModuleElement* (page 2729), because the module *C* to which the result will belong will be the nearest common ancestor (NCA) of the modules *A*, *B* to which the two operands belong, and *C* may be different from either or both of *A* and *B*.

```

>>> A = PowerBasis(T)
>>> B = A.submodule_from_matrix(2 * DomainMatrix.eye(4, ZZ))
>>> C = A.submodule_from_matrix(3 * DomainMatrix.eye(4, ZZ))
>>> print((B(0) * C(0)).module == A)
True

```

Before the arithmetic operation is performed, copies of the two operands are automatically converted into elements of the NCA (the operands themselves are not modified). This upward conversion along an ancestor chain is easy: it just requires the successive multiplication by the defining matrix of each *Submodule* (page 2726).

Conversely, downward conversion, i.e. representing a given *ModuleElement* (page 2729) in a submodule, is also supported – namely by the *represent()* (page 2729) method – but is not guaranteed to succeed in general, since the given element may not belong to the submodule. The main circumstance in which this issue tends to arise is with multiplication, since modules, while closed under addition, need not be closed under multiplication.

## Multiplication

Generally speaking, a module need not be closed under multiplication, i.e. need not form a ring. However, many of the modules we work with in the context of number fields are in fact rings, and our classes do support multiplication.

Specifically, any *Module* (page 2719) can attempt to compute its own multiplication table, but this does not happen unless an attempt is made to multiply two *ModuleElement* (page 2729) instances belonging to it.

```

>>> A = PowerBasis(T)
>>> print(A._mult_tab is None)
True
>>> a = A(0)*A(1)
>>> print(A._mult_tab is None)
False

```

Every *PowerBasis* (page 2725) is, by its nature, closed under multiplication, so instances of *PowerBasis* (page 2725) can always successfully compute their multiplication table.

When a *Submodule* (page 2726) attempts to compute its multiplication table, it converts each of its own generators into elements of its parent module, multiplies them there, in every possible pairing, and then tries to represent the results in itself, i.e. as  $\mathbb{Z}$ -linear combinations over its own generators. This will succeed if and only if the submodule is in fact closed under multiplication.

## Module Homomorphisms

Many important number theoretic algorithms require the calculation of the kernel of one or more module homomorphisms. Accordingly we have several lightweight classes, *ModuleHomomorphism* (page 2733), *ModuleEndomorphism* (page 2734), *InnerEndomorphism* (page 2734), and *EndomorphismRing* (page 2734), which provide the minimal necessary machinery to support this.

## Class Reference

**class** sympy.polys.numberfields.modules.**Module**

Generic finitely-generated module.

This is an abstract base class, and should not be instantiated directly. The two concrete subclasses are *PowerBasis* (page 2725) and *Submodule* (page 2726).

Every *Submodule* (page 2726) is derived from another module, referenced by its parent attribute. If *S* is a submodule, then we refer to *S.parent*, *S.parent.parent*, and so on, as the “ancestors” of *S*. Thus, every *Module* (page 2719) is either a *PowerBasis* (page 2725) or a *Submodule* (page 2726), some ancestor of which is a *PowerBasis* (page 2725).

**\_\_call\_\_**(*spec*, *denom*=1)

Generate a *ModuleElement* (page 2729) belonging to this module.

### Parameters

**spec** : *DomainMatrix* (page 2671), int

Specifies the numerators of the coefficients of the *ModuleElement* (page 2729). Can be either a column vector over *ZZ* (page 2525), whose length must equal the number *n* of generators of this module, or else an integer *j*,  $0 \leq j < n$ , which is a shorthand for column *j* of *I<sub>n</sub>*, the  $n \times n$  identity matrix.

**denom** : int, optional (default=1)

Denominator for the coefficients of the *ModuleElement* (page 2729).

### Returns

*ModuleElement* (page 2729)

The coefficients are the entries of the *spec* vector, divided by *denom*.

### Examples

```
>>> from sympy.polys import Poly, cyclotomic_poly
>>> from sympy.polys.numberfields.modules import PowerBasis, to_col
>>> T = Poly(cyclotomic_poly(5))
>>> A = PowerBasis(T)
>>> e = A(to_col([1, 2, 3, 4]), denom=3)
>>> print(e)
[1, 2, 3, 4]/3
>>> f = A(2)
>>> print(f)
[0, 0, 1, 0]
```

**ancestors**(*include\_self=False*)

Return the list of ancestor modules of this module, from the foundational *PowerBasis* (page 2725) downward, optionally including *self*.

**See also:**

*Module* (page 2719)

**basis\_elements**()

Get list of *ModuleElement* (page 2729) being the generators of this module.

**element\_from\_rational**(*a*)

Return a *ModuleElement* (page 2729) representing a rational number.

**Parameters**

**a** : int, *ZZ* (page 2525), *QQ* (page 2529)

**Returns**

*ModuleElement* (page 2729)

### Explanation

The returned *ModuleElement* (page 2729) will belong to the first module on this module's ancestor chain (including this module itself) that starts with unity.

### Examples

```
>>> from sympy.polys import Poly, cyclotomic_poly, QQ
>>> from sympy.polys.numberfields.modules import PowerBasis
>>> T = Poly(cyclotomic_poly(5))
>>> A = PowerBasis(T)
>>> a = A.element_from_rational(QQ(2, 3))
>>> print(a)
[2, 0, 0, 0]/3
```

**endomorphism\_ring**()

Form the *EndomorphismRing* (page 2734) for this module.

**is\_compat\_col**(*col*)

Say whether *col* is a suitable column vector for this module.

**mult\_tab**()

Get the multiplication table for this module (if closed under mult).

**Returns**

dict of dict of lists

**Raises**

**ClosureFailure**

If the module is not closed under multiplication.

## Explanation

Computes a dictionary *M* of dictionaries of lists, representing the upper triangular half of the multiplication table.

In other words, if  $0 \leq i \leq j < \text{self.n}$ , then *M*[*i*][*j*] is the list *c* of coefficients such that  $g[i] * g[j] == \sum(c[k]*g[k], k \text{ in range}(\text{self.n}))$ , where *g* is the list of generators of this module.

If  $j < i$  then *M*[*i*][*j*] is undefined.

## Examples

```
>>> from sympy.polys import Poly, cyclotomic_poly
>>> from sympy.polys.numberfields.modules import PowerBasis
>>> T = Poly(cyclotomic_poly(5))
>>> A = PowerBasis(T)
>>> print(A.mult_tab())
{0: {0: [1, 0, 0, 0], 1: [0, 1, 0, 0], 2: [0, 0, 1, 0], 3: [0, 0, 0, 1],
 ↪ 0, 1]},
 1: {1: [0, 0, 1, 0], 2: [0, 0, 0, 1], 3: [-1, -1, -1, -1]},
 ↪ 1, -1, -1]},
 2: {2: [-1, -1, -1, -1], 3: [1, 0, 0, 1]},
 ↪ 0, 0]},
 3: {3: [0, 1, 0, 1], 0: [1, 0, 0, 0], 1: [0, 1, 0, 0], 2: [0, 0, 1, 0]},
 ↪ 0, 0]}}
```

**property n**

The number of generators of this module.

**nearest\_common\_ancestor**(*other*)

Locate the nearest common ancestor of this module and another.

**Returns**

[Module](#) (page 2719), None

**See also:**

[Module](#) (page 2719)

**property number\_field**

Return the associated *AlgebraicField* (page 2539), if any.

**Returns**

*AlgebraicField* (page 2539), None

**Explanation**

A *PowerBasis* (page 2725) can be constructed on a *Poly* (page 2378)  $f$  or on an *AlgebraicField* (page 2539)  $K$ . In the latter case, the *PowerBasis* (page 2725) and all its descendant modules will return  $K$  as their `.number_field` property, while in the former case they will all return None.

**one()**

Return a *ModuleElement* (page 2729) representing unity, and belonging to the first ancestor of this module (including itself) that starts with unity.

**property parent**

The parent module, if any, for this module.

**Returns**

*Module* (page 2719), None

**Explanation**

For a *Submodule* (page 2726) this is its parent attribute; for a *PowerBasis* (page 2725) this is None.

**See also:**

*Module* (page 2719)

**power\_basis\_ancestor()**

Return the *PowerBasis* (page 2725) that is an ancestor of this module.

**See also:**

*Module* (page 2719)

**represent(elt)**

Represent a module element as an integer-linear combination over the generators of this module.

**Parameters**

**elt** : *ModuleElement* (page 2729)

The module element to be represented. Must belong to some ancestor module of this module (including this module itself).

**Returns**

*DomainMatrix* (page 2671) over *ZZ* (page 2525)

This will be a column vector, representing the coefficients of a linear combination of this module's generators, which equals the given element.

**Raises**

**ClosureFailure**

If the given element cannot be represented as a [ZZ](#) (page 2525)-linear combination over this module.

### Explanation

In our system, to “represent” always means to write a [ModuleElement](#) (page 2729) as a [ZZ](#) (page 2525)-linear combination over the generators of the present [Module](#) (page 2719). Furthermore, the incoming [ModuleElement](#) (page 2729) must belong to an ancestor of the present [Module](#) (page 2719) (or to the present [Module](#) (page 2719) itself).

The most common application is to represent a [ModuleElement](#) (page 2729) in a [Submodule](#) (page 2726). For example, this is involved in computing multiplication tables.

On the other hand, representing in a [PowerBasis](#) (page 2725) is an odd case, and one which tends not to arise in practice, except for example when using a [ModuleEndomorphism](#) (page 2734) on a [PowerBasis](#) (page 2725).

In such a case, (1) the incoming [ModuleElement](#) (page 2729) must belong to the [PowerBasis](#) (page 2725) itself (since the latter has no proper ancestors) and (2) it is “representable” iff it belongs to  $\mathbb{Z}[\theta]$  (although generally a [PowerBasisElement](#) (page 2732) may represent any element of  $\mathbb{Q}(\theta)$ , i.e. any algebraic number).

### Examples

```
>>> from sympy import Poly, cyclotomic_poly
>>> from sympy.polys.numberfields.modules import PowerBasis, to_col
>>> from sympy.abc import zeta
>>> T = Poly(cyclotomic_poly(5))
>>> A = PowerBasis(T)
>>> a = A(to_col([2, 4, 6, 8]))
```

The [ModuleElement](#) (page 2729) `a` has all even coefficients. If we represent `a` in the submodule `B = 2*A`, the coefficients in the column vector will be halved:

```
>>> B = A.submodule_from_gens([2*A(i) for i in range(4)])
>>> b = B.represent(a)
>>> print(b.transpose())
DomainMatrix([[1, 2, 3, 4]], (1, 4), ZZ)
```

However, the element of `B` so defined still represents the same algebraic number:

```
>>> print(a.poly(zeta).as_expr())
8*zeta**3 + 6*zeta**2 + 4*zeta + 2
>>> print(B(b).over_power_basis().poly(zeta).as_expr())
8*zeta**3 + 6*zeta**2 + 4*zeta + 2
```

### See also:

[Submodule.represent](#) (page 2729), [PowerBasis.represent](#) (page 2725)

### `starts_with_unity()`

Say whether the module’s first generator equals unity.

**submodule\_from\_gens**(*gens*, *hnf*=True, *hnf\_modulus*=None)

Form the submodule generated by a list of [ModuleElement](#) (page 2729) belonging to this module.

**Parameters**

**gens** : list of [ModuleElement](#) (page 2729) belonging to this module.

**hnf** : boolean, optional (default=True)

If True, we will reduce the matrix into Hermite Normal Form before forming the [Submodule](#) (page 2726).

**hnf\_modulus** : int, None, optional (default=None)

Modulus for use in the HNF reduction algorithm. See [hermite\\_normal\\_form\(\)](#) (page 2700).

**Returns**

[Submodule](#) (page 2726)

**Examples**

```
>>> from sympy.polys import Poly, cyclotomic_poly
>>> from sympy.polys.numberfields.modules import PowerBasis
>>> T = Poly(cyclotomic_poly(5))
>>> A = PowerBasis(T)
>>> gens = [A(0), 2*A(1), 3*A(2), 4*A(3)//5]
>>> B = A.submodule_from_gens(gens)
>>> print(B)
Submodule[[5, 0, 0, 0], [0, 10, 0, 0], [0, 0, 15, 0], [0, 0, 0, 4]]/5
```

**See also:**

[submodule\\_from\\_matrix](#) (page 2724)

**submodule\_from\_matrix**(*B*, *denom*=1)

Form the submodule generated by the elements of this module indicated by the columns of a matrix, with an optional denominator.

**Parameters**

**B** : [DomainMatrix](#) (page 2671) over [ZZ](#) (page 2525)

Each column gives the numerators of the coefficients of one generator of the submodule. Thus, the number of rows of *B* must equal the number of generators of the present module.

**denom** : int, optional (default=1)

Common denominator for all generators of the submodule.

**Returns**

[Submodule](#) (page 2726)

**Raises**

**ValueError**

If the given matrix *B* is not over [ZZ](#) (page 2525) or its number of rows does not equal the number of generators of the present module.

## Examples

```
>>> from sympy.polys import Poly, cyclotomic_poly, ZZ
>>> from sympy.polys.matrices import DM
>>> from sympy.polys.numberfields.modules import PowerBasis
>>> T = Poly(cyclotomic_poly(5))
>>> A = PowerBasis(T)
>>> B = A.submodule_from_matrix(DM([
... [0, 10, 0, 0],
... [0, 0, 7, 0],
...], ZZ).transpose(), denom=15)
>>> print(B)
Submodule[[0, 10, 0, 0], [0, 0, 7, 0]]/15
```

### See also:

[submodule\\_from\\_gens](#) (page 2723)

### `whole_submodule()`

Return a submodule equal to this entire module.

## Explanation

This is useful when you have a [PowerBasis](#) (page 2725) and want to turn it into a [Submodule](#) (page 2726) (in order to use methods belonging to the latter).

### `zero()`

Return a [ModuleElement](#) (page 2729) representing zero.

### `class sympy.polys.numberfields.modules.PowerBasis(T)`

The module generated by the powers of an algebraic integer.

### `__init__(T)`

#### Parameters

**T** : [Poly](#) (page 2378), [AlgebraicField](#) (page 2539)

Either (1) the monic, irreducible, univariate polynomial over [ZZ](#) (page 2525), a root of which is the generator of the power basis, or (2) an [AlgebraicField](#) (page 2539) whose primitive element is the generator of the power basis.

### `element_from_ANP(a)`

Convert an ANP into a PowerBasisElement.

### `element_from_alg_num(a)`

Convert an AlgebraicNumber into a PowerBasisElement.

### `element_from_poly(f)`

Produce an element of this module, representing  $f$  after reduction mod our defining minimal polynomial.

#### Parameters

**f** : [Poly](#) (page 2378) over [ZZ](#) (page 2525) in same var as our defining poly.

#### Returns

[PowerBasisElement](#) (page 2732)

**represent**(*elt*)

Represent a module element as an integer-linear combination over the generators of this module.

**See also:**

[Module.represent](#) (page 2722), [Submodule.represent](#) (page 2729)

**class** sympy.polys.numberfields.modules.**Submodule**(*parent, matrix, denom=1, mult\_tab=None*)

A submodule of another module.

**\_\_init\_\_**(*parent, matrix, denom=1, mult\_tab=None*)

**Parameters**

**parent** : [Module](#) (page 2719)

The module from which this one is derived.

**matrix** : [DomainMatrix](#) (page 2671) over [ZZ](#) (page 2525)

The matrix whose columns define this submodule's generators as linear combinations over the parent's generators.

**denom** : int, optional (default=1)

Denominator for the coefficients given by the matrix.

**mult\_tab** : dict, None, optional

If already known, the multiplication table for this module may be supplied.

**property QQ\_matrix**

[DomainMatrix](#) (page 2671) over [QQ](#) (page 2529), equal to `self.matrix / self.denom`, and guaranteed to be dense.

**Returns**

[DomainMatrix](#) (page 2671) over [QQ](#) (page 2529)

**Explanation**

Depending on how it is formed, a [DomainMatrix](#) (page 2671) may have an internal representation that is sparse or dense. We guarantee a dense representation here, so that tests for equivalence of submodules always come out as expected.

**Examples**

```
>>> from sympy.polys import Poly, cyclotomic_poly, ZZ
>>> from sympy.abc import x
>>> from sympy.polys.matrices import DomainMatrix
>>> from sympy.polys.numberfields.modules import PowerBasis
>>> T = Poly(cyclotomic_poly(5, x))
>>> A = PowerBasis(T)
>>> B = A.submodule_from_matrix(3*DomainMatrix.eye(4, ZZ), denom=6)
>>> C = A.submodule_from_matrix(DomainMatrix.eye(4, ZZ), denom=2)
```

(continues on next page)

(continued from previous page)

```
>>> print(B.QQ_matrix == C.QQ_matrix)
True
```

**add**(*other*, *hnf*=True, *hnf\_modulus*=None)

Add this [Submodule](#) (page 2726) to another.

**Parameters**

**other** : [Submodule](#) (page 2726)

**hnf** : boolean, optional (default=True)

If True, reduce the matrix of the combined module to its Hermite Normal Form.

**hnf\_modulus** : [ZZ](#) (page 2525), None, optional

If a positive integer is provided, use this as modulus in the HNF reduction. See [hermite\\_normal\\_form\(\)](#) (page 2700).

**Returns**

[Submodule](#) (page 2726)

**Explanation**

This represents the module generated by the union of the two modules' sets of generators.

**basis\_element\_pullbacks()**

Return list of this submodule's basis elements as elements of the submodule's parent module.

**discard\_before(r)**

Produce a new module by discarding all generators before a given index *r*.

**mul**(*other*, *hnf*=True, *hnf\_modulus*=None)

Multiply this [Submodule](#) (page 2726) by a rational number, a [ModuleElement](#) (page 2729), or another [Submodule](#) (page 2726).

**Parameters**

**other** : int, [ZZ](#) (page 2525), [QQ](#) (page 2529), [ModuleElement](#) (page 2729), [Submodule](#) (page 2726)

**hnf** : boolean, optional (default=True)

If True, reduce the matrix of the product module to its Hermite Normal Form.

**hnf\_modulus** : [ZZ](#) (page 2525), None, optional

If a positive integer is provided, use this as modulus in the HNF reduction. See [hermite\\_normal\\_form\(\)](#) (page 2700).

**Returns**

[Submodule](#) (page 2726)

### Explanation

To multiply by a rational number or [ModuleElement](#) (page 2729) means to form the submodule whose generators are the products of this quantity with all the generators of the present submodule.

To multiply by another [Submodule](#) (page 2726) means to form the submodule whose generators are all the products of one generator from the one submodule, and one generator from the other.

#### `reduce_element(elt)`

If this submodule  $B$  has defining matrix  $W$  in square, maximal-rank Hermite normal form, then, given an element  $x$  of the parent module  $A$ , we produce an element  $y \in A$  such that  $x - y \in B$ , and the  $i$ th coordinate of  $y$  satisfies  $0 \leq y_i < w_{i,i}$ . This representative  $y$  is unique, in the sense that every element of the coset  $x + B$  reduces to it under this procedure.

##### Parameters

**elt** : [ModuleElement](#) (page 2729)

An element of this submodule's parent module.

##### Returns

**elt** : [ModuleElement](#) (page 2729)

An element of this submodule's parent module.

##### Raises

###### **NotImplementedError**

If the given [ModuleElement](#) (page 2729) does not belong to this submodule's parent module.

###### **StructureError**

If this submodule's defining matrix is not in square, maximal-rank Hermite normal form.

### Explanation

In the special case where  $A$  is a power basis for a number field  $K$ , and  $B$  is a submodule representing an ideal  $I$ , this operation represents one of a few important ways of reducing an element of  $K$  modulo  $I$  to obtain a “small” representative. See [Cohen00] Section 1.4.3.

### Examples

```
>>> from sympy import QQ, Poly, symbols
>>> t = symbols('t')
>>> k = QQ.alg_field_from_poly(Poly(t**3 + t**2 - 2*t + 8))
>>> Zk = k.maximal_order()
>>> A = Zk.parent
>>> B = (A(2) - 3*A(0))*Zk
>>> B.reduce_element(A(2))
[3, 0, 0]
```

## References

[Cohen00]

### **reduced()**

Produce a reduced version of this submodule.

#### **Returns**

*Submodule* (page 2726)

## Explanation

In the reduced version, it is guaranteed that 1 is the only positive integer dividing both the submodule's denominator, and every entry in the submodule's matrix.

### **represent(elt)**

Represent a module element as an integer-linear combination over the generators of this module.

#### **See also:**

*Module.represent* (page 2722), *PowerBasis.represent* (page 2725)

**class** sympy.polys.numberfields.modules.**ModuleElement**(*module*, *col*, *denom*=1)

Represents an element of a *Module* (page 2719).

NOTE: Should not be constructed directly. Use the `__call__()` (page 2719) method or the `make_mod_elt()` (page 2733) factory function instead.

**\_\_init\_\_**(*module*, *col*, *denom*=1)

#### **Parameters**

**module** : *Module* (page 2719)

The module to which this element belongs.

**col** : *DomainMatrix* (page 2671) over *ZZ* (page 2525)

Column vector giving the numerators of the coefficients of this element.

**denom** : int, optional (default=1)

Denominator for the coefficients of this element.

**\_\_add\_\_**(*other*)

A *ModuleElement* (page 2729) can be added to a rational number, or to another *ModuleElement* (page 2729).

### Explanation

When the other summand is a rational number, it will be converted into a [ModuleElement](#) (page 2729) (belonging to the first ancestor of this module that starts with unity).

In all cases, the sum belongs to the nearest common ancestor (NCA) of the modules of the two summands. If the NCA does not exist, we return `NotImplemented`.

`__mul__(other)`

A [ModuleElement](#) (page 2729) can be multiplied by a rational number, or by another [ModuleElement](#) (page 2729).

### Explanation

When the multiplier is a rational number, the product is computed by operating directly on the coefficients of this [ModuleElement](#) (page 2729).

When the multiplier is another [ModuleElement](#) (page 2729), the product will belong to the nearest common ancestor (NCA) of the modules of the two operands, and that NCA must have a multiplication table. If the NCA does not exist, we return `NotImplemented`. If the NCA does not have a mult. table, `ClosureFailure` will be raised.

`__mod__(m)`

Reduce this [ModuleElement](#) (page 2729) mod a [Submodule](#) (page 2726).

#### Parameters

**m** : int, [ZZ](#) (page 2525), [QQ](#) (page 2529), [Submodule](#) (page 2726)

If a [Submodule](#) (page 2726), reduce `self` relative to this. If an integer or rational, reduce relative to the [Submodule](#) (page 2726) that is our own module times this constant.

#### See also:

[Submodule.reduce\\_element](#) (page 2728)

**property** `QQ_col`

[DomainMatrix](#) (page 2671) over [QQ](#) (page 2529), equal to `self.col / self.denom`, and guaranteed to be dense.

#### See also:

[Submodule.QQ\\_matrix](#) (page 2726)

**column**(*domain=None*)

Get a copy of this element's column, optionally converting to a domain.

**equiv**(*other*)

A [ModuleElement](#) (page 2729) may test as equivalent to a rational number or another [ModuleElement](#) (page 2729), if they represent the same algebraic number.

#### Parameters

**other** : int, [ZZ](#) (page 2525), [QQ](#) (page 2529), [ModuleElement](#) (page 2729)

#### Returns

bool

**Raises****UnificationFailed**

If `self` and `other` do not share a common [PowerBasis](#) (page 2725) ancestor.

**Explanation**

This method is intended to check equivalence only in those cases in which it is easy to test; namely, when `other` is either a [ModuleElement](#) (page 2729) that can be unified with this one (i.e. one which shares a common [PowerBasis](#) (page 2725) ancestor), or else a rational number (which is easy because every [PowerBasis](#) (page 2725) represents every rational number).

**classmethod** `from_int_list(module, coeffs, denom=1)`

Make a [ModuleElement](#) (page 2729) from a list of ints (instead of a column vector).

**is\_compat**(`other`)

Test whether `other` is another [ModuleElement](#) (page 2729) with same module.

**property** `n`

The length of this element's column.

**over\_power\_basis**()

Transform into a [PowerBasisElement](#) (page 2732) over our [PowerBasis](#) (page 2725) ancestor.

**reduced**()

Produce a reduced version of this [ModuleElement](#), i.e. one in which the gcd of the denominator together with all numerator coefficients is 1.

**reduced\_mod\_p**(`p`)

Produce a version of this [ModuleElement](#) (page 2729) in which all numerator coefficients have been reduced mod `p`.

**to\_ancestor**(`anc`)

Transform into a [ModuleElement](#) (page 2729) belonging to a given ancestor of this element's module.

**Parameters**

**anc** : [Module](#) (page 2719)

**to\_parent**()

Transform into a [ModuleElement](#) (page 2729) belonging to the parent of this element's module.

**unify**(`other`)

Try to make a compatible pair of [ModuleElement](#) (page 2729), one equivalent to this one, and one equivalent to the other.

**Returns**

Pair (`e1`, `e2`)

Each `ei` is a [ModuleElement](#) (page 2729), they belong to the same [Module](#) (page 2719), `e1` is equivalent to `self`, and `e2` is equivalent to `other`.

**Raises****UnificationFailed**

If self and other have no common ancestor module.

**Explanation**

We search for the nearest common ancestor module for the pair of elements, and represent each one there.

**class** sympy.polys.numberfields.modules.**PowerBasisElement**(*module, col, denom=1*)  
Subclass for *ModuleElement* (page 2729) instances whose module is a *PowerBasis* (page 2725).

**property T**

Access the defining polynomial of the *PowerBasis* (page 2725).

**as\_expr**(*x=None*)

Create a Basic expression from self.

**property generator**

Return a *Symbol* (page 976) to be used when expressing this element as a polynomial.

If we have an associated *AlgebraicField* (page 2539) whose primitive element has an alias symbol, we use that. Otherwise we use the variable of the minimal polynomial defining the power basis to which we belong.

**property is\_rational**

Say whether this element represents a rational number.

**norm**(*T=None*)

Compute the norm of this number.

**numerator**(*x=None*)

Obtain the numerator as a polynomial over *ZZ* (page 2525).

**poly**(*x=None*)

Obtain the number as a polynomial over *QQ* (page 2529).

**to\_ANP**()

Convert to an equivalent *ANP* (page 2568).

**to\_alg\_num**()

Try to convert to an equivalent *AlgebraicNumber* (page 988).

**Returns**

*AlgebraicNumber* (page 988)

**Raises****StructureError**

If the *PowerBasis* (page 2725) to which this element belongs does not have an associated *AlgebraicField* (page 2539).

## Explanation

In general, the conversion from an *AlgebraicNumber* (page 988) to a *PowerBasisElement* (page 2732) throws away information, because an *AlgebraicNumber* (page 988) specifies a complex embedding, while a *PowerBasisElement* (page 2732) does not. However, in some cases it is possible to convert a *PowerBasisElement* (page 2732) back into an *AlgebraicNumber* (page 988), namely when the associated *PowerBasis* (page 2725) has a reference to an *AlgebraicField* (page 2539).

`sympy.polys.numberfields.modules.make_mod_elt(module, col, denom=1)`

Factory function which builds a *ModuleElement* (page 2729), but ensures that it is a *PowerBasisElement* (page 2732) if the module is a *PowerBasis* (page 2725).

**class** `sympy.polys.numberfields.modules.ModuleHomomorphism(domain, codomain, mapping)`

A homomorphism from one module to another.

**\_\_init\_\_**(*domain*, *codomain*, *mapping*)

### Parameters

**domain** : *Module* (page 2719)

The domain of the mapping.

**codomain** : *Module* (page 2719)

The codomain of the mapping.

**mapping** : callable

An arbitrary callable is accepted, but should be chosen so as to represent an actual module homomorphism. In particular, should accept elements of *domain* and return elements of *codomain*.

## Examples

```
>>> from sympy import Poly, cyclotomic_poly
>>> from sympy.polys.numberfields.modules import PowerBasis, \
↳ ModuleHomomorphism
>>> T = Poly(cyclotomic_poly(5))
>>> A = PowerBasis(T)
>>> B = A.submodule_from_gens([2*A(j) for j in range(4)])
>>> phi = ModuleHomomorphism(A, B, lambda x: 6*x)
>>> print(phi.matrix())
DomainMatrix([[3, 0, 0, 0], [0, 3, 0, 0], [0, 0, 3, 0], [0, 0, 0, 3]],
↳ (4, 4), ZZ)
```

**kernel**(*modulus=None*)

Compute a Submodule representing the kernel of this homomorphism.

### Parameters

**modulus** : int, optional

A positive prime number  $p$  if the kernel should be computed mod  $p$ .

### Returns

*Submodule* (page 2726)

This submodule's generators span the kernel of this homomorphism over [ZZ](#) (page 2525), or else over [GF\(p\)](#) (page 2522) if a modulus was given.

**matrix**(*modulus=None*)

Compute the matrix of this homomorphism.

**Parameters**

**modulus** : int, optional

A positive prime number  $p$  if the matrix should be reduced mod  $p$ .

**Returns**

[DomainMatrix](#) (page 2671)

The matrix is over [ZZ](#) (page 2525), or else over [GF\(p\)](#) (page 2522) if a modulus was given.

**class** sympy.polys.numberfields.modules.**ModuleEndomorphism**(*domain, mapping*)

A homomorphism from one module to itself.

**\_\_init\_\_**(*domain, mapping*)

**Parameters**

**domain** : [Module](#) (page 2719)

The common domain and codomain of the mapping.

**mapping** : callable

An arbitrary callable is accepted, but should be chosen so as to represent an actual module endomorphism. In particular, should accept and return elements of *domain*.

**class** sympy.polys.numberfields.modules.**InnerEndomorphism**(*domain, multiplier*)

An inner endomorphism on a module, i.e. the endomorphism corresponding to multiplication by a fixed element.

**\_\_init\_\_**(*domain, multiplier*)

**Parameters**

**domain** : [Module](#) (page 2719)

The domain and codomain of the endomorphism.

**multiplier** : [ModuleElement](#) (page 2729)

The element  $a$  defining the mapping as  $x \mapsto ax$ .

**class** sympy.polys.numberfields.modules.**EndomorphismRing**(*domain*)

The ring of endomorphisms on a module.

**\_\_init\_\_**(*domain*)

**Parameters**

**domain** : [Module](#) (page 2719)

The domain and codomain of the endomorphisms.

**inner\_endomorphism**(*multiplier*)

Form an inner endomorphism belonging to this endomorphism ring.

**Parameters**

**multiplier** : [ModuleElement](#) (page 2729)

Element  $a$  defining the inner endomorphism  $x \mapsto ax$ .

### Returns

[\*InnerEndomorphism\*](#) (page 2734)

### `represent(element)`

Represent an element of this endomorphism ring, as a single column vector.

### Parameters

**element** : [\*ModuleEndomorphism\*](#) (page 2734) belonging to this ring.

### Returns

[\*DomainMatrix\*](#) (page 2671)

Column vector equalling the vertical stacking of all the columns of the matrix that represents the given *element* as a mapping.

## Explanation

Let  $M$  be a module, and  $E$  its ring of endomorphisms. Let  $N$  be another module, and consider a homomorphism  $\varphi : N \rightarrow E$ . In the event that  $\varphi$  is to be represented by a matrix  $A$ , each column of  $A$  must represent an element of  $E$ . This is possible when the elements of  $E$  are themselves representable as matrices, by stacking the columns of such a matrix into a single column.

This method supports calculating such matrices  $A$ , by representing an element of this endomorphism ring first as a matrix, and then stacking that matrix's columns into a single column.

## Examples

Note that in these examples we print matrix transposes, to make their columns easier to inspect.

```
>>> from sympy import Poly, cyclotomic_poly
>>> from sympy.polys.numberfields.modules import PowerBasis
>>> from sympy.polys.numberfields.modules import ModuleHomomorphism
>>> T = Poly(cyclotomic_poly(5))
>>> M = PowerBasis(T)
>>> E = M.endomorphism_ring()
```

Let  $\zeta$  be a primitive 5th root of unity, a generator of our field, and consider the inner endomorphism  $\tau$  on the ring of integers, induced by  $\zeta$ :

```
>>> zeta = M(1)
>>> tau = E.inner_endomorphism(zeta)
>>> tau.matrix().transpose()
DomainMatrix(
 [[0, 1, 0, 0], [0, 0, 1, 0], [0, 0, 0, 1], [-1, -1, -1, -1]],
 (4, 4), ZZ)
```

The matrix representation of  $\tau$  is as expected. The first column shows that multiplying by  $\zeta$  carries 1 to  $\zeta$ , the second column that it carries  $\zeta$  to  $\zeta^2$ , and so forth.

The `represent` method of the endomorphism ring  $E$  stacks these into a single column:

```
>>> E.represent(tau).transpose()
DomainMatrix(
 [[0, 1, 0, 0, 0, 0, 1, 0, 0, 0, 0, 1, -1, -1, -1, -1]],
 (1, 16), ZZ)
```

This is useful when we want to consider a homomorphism  $\varphi$  having  $E$  as codomain:

```
>>> phi = ModuleHomomorphism(M, E, lambda x: E.inner_endomorphism(x))
```

and we want to compute the matrix of such a homomorphism:

```
>>> phi.matrix().transpose()
DomainMatrix(
 [[1, 0, 0, 0, 0, 0, 1, 0, 0, 0, 0, 1, 0, 0, 0, 0, 1],
 [0, 1, 0, 0, 0, 0, 0, 1, 0, 0, 0, 0, 1, -1, -1, -1, -1],
 [0, 0, 1, 0, 0, 0, 0, 0, 1, -1, -1, -1, -1, 1, 0, 0, 0],
 [0, 0, 0, 1, -1, -1, -1, -1, 1, 0, 0, 0, 0, 1, 0, 0, 0]],
 (4, 16), ZZ)
```

Note that the stacked matrix of  $\tau$  occurs as the second column in this example. This is because  $\zeta$  is the second basis element of  $M$ , and  $\varphi(\zeta) = \tau$ .

`sympy.polys.numberfields.modules.find_min_poly(alpha, domain, x=None, powers=None)`

Find a polynomial of least degree (not necessarily irreducible) satisfied by an element of a finitely-generated ring with unity.

#### Parameters

**alpha** : *ModuleElement* (page 2729)

The element whose min poly is to be found, and whose module has multiplication and starts with unity.

**domain** : *Domain* (page 2504)

The desired domain of the polynomial.

**x** : *Symbol* (page 976), optional

The desired variable for the polynomial.

**powers** : list, optional

If desired, pass an empty list. The powers of *alpha* (as *ModuleElement* (page 2729) instances) from the zeroth up to the degree of the min poly will be recorded here, as we compute them.

#### Returns

*Poly* (page 2378), None

The minimal polynomial for *alpha*, or None if no polynomial could be found over the desired domain.

#### Raises

**MissingUnityError**

If the module to which *alpha* belongs does not start with unity.

**ClosureFailure**

If the module to which alpha belongs is not closed under multiplication.

## Examples

For the  $n$ th cyclotomic field,  $n$  an odd prime, consider the quadratic equation whose roots are the two periods of length  $(n-1)/2$ . Article 356 of Gauss tells us that we should get  $x^2 + x - (n-1)/4$  or  $x^2 + x + (n+1)/4$  according to whether  $n$  is 1 or 3 mod 4, respectively.

```
>>> from sympy import Poly, cyclotomic_poly, primitive_root, QQ
>>> from sympy.abc import x
>>> from sympy.polys.numberfields.modules import PowerBasis, find_min_
 poly
>>> n = 13
>>> g = primitive_root(n)
>>> C = PowerBasis(Poly(cyclotomic_poly(n, x)))
>>> ee = [g**(2*k+1) % n for k in range((n-1)//2)]
>>> eta = sum(C(e) for e in ee)
>>> print(find_min_poly(eta, QQ, x=x).as_expr())
x**2 + x - 3
>>> n = 19
>>> g = primitive_root(n)
>>> C = PowerBasis(Poly(cyclotomic_poly(n, x)))
>>> ee = [g**(2*k+2) % n for k in range((n-1)//2)]
>>> eta = sum(C(e) for e in ee)
>>> print(find_min_poly(eta, QQ, x=x).as_expr())
x**2 + x + 5
```

## Utilities

`sympy.polys.numberfields.utilities.is_rat(c)`

Test whether an argument is of an acceptable type to be used as a rational number.

### Explanation

Returns True on any argument of type `int`, `ZZ` (page 2525), or `QQ` (page 2529).

**See also:**

`is_int` (page 2737)

`sympy.polys.numberfields.utilities.is_int(c)`

Test whether an argument is of an acceptable type to be used as an integer.

### Explanation

Returns True on any argument of type int or [ZZ](#) (page 2525).

#### See also:

[is\\_rat](#) (page 2737)

`sympy.polys.numberfields.utilities.get_num_denom(c)`

Given any argument on which [is\\_rat\(\)](#) (page 2737) is True, return the numerator and denominator of this number.

#### See also:

[is\\_rat](#) (page 2737)

`sympy.polys.numberfields.utilities.extract_fundamental_discriminant(a)`

Extract a fundamental discriminant from an integer  $a$ .

#### Parameters

**a:** int, must be 0 or 1 mod 4

#### Returns

Pair (D, F) of dictionaries.

#### Raises

##### ValueError

If  $a$  is not 0 or 1 mod 4.

### Explanation

Given any rational integer  $a$  that is 0 or 1 mod 4, write  $a = df^2$ , where  $d$  is either 1 or a fundamental discriminant, and return a pair of dictionaries (D, F) giving the prime factorizations of  $d$  and  $f$  respectively, in the same format returned by [factorint\(\)](#) (page 1493).

A fundamental discriminant  $d$  is different from unity, and is either 1 mod 4 and squarefree, or is 0 mod 4 and such that  $d/4$  is squarefree and 2 or 3 mod 4. This is the same as being the discriminant of some quadratic field.

### Examples

```
>>> from sympy.polys.numberfields.utilities import extract_fundamental_
↪discriminant
>>> print(extract_fundamental_discriminant(-432))
({3: 1, -1: 1}, {2: 2, 3: 1})
```

For comparison:

```
>>> from sympy import factorint
>>> print(factorint(-432))
{2: 4, 3: 3, -1: 1}
```

## References

[R716]

**class** sympy.polys.numberfields.utilities.**AlgIntPowers**(*T*, *modulus=None*)

Compute the powers of an algebraic integer.

## Explanation

Given an algebraic integer  $\theta$  by its monic irreducible polynomial  $T$  over [ZZ](#) (page 2525), this class computes representations of arbitrarily high powers of  $\theta$ , as [ZZ](#) (page 2525)-linear combinations over  $\{1, \theta, \dots, \theta^{n-1}\}$ , where  $n = \deg(T)$ .

The representations are computed using the linear recurrence relations for powers of  $\theta$ , derived from the polynomial  $T$ . See [1], Sec. 4.2.2.

Optionally, the representations may be reduced with respect to a modulus.

## Examples

```
>>> from sympy import Poly, cyclotomic_poly
>>> from sympy.polys.numberfields.utilities import AlgIntPowers
>>> T = Poly(cyclotomic_poly(5))
>>> zeta_pow = AlgIntPowers(T)
>>> print(zeta_pow[0])
[1, 0, 0, 0]
>>> print(zeta_pow[1])
[0, 1, 0, 0]
>>> print(zeta_pow[4])
[-1, -1, -1, -1]
>>> print(zeta_pow[24])
[-1, -1, -1, -1]
```

## References

[R717]

**\_\_init\_\_**(*T*, *modulus=None*)

### Parameters

**T** : [Poly](#) (page 2378)

The monic irreducible polynomial over [ZZ](#) (page 2525) defining the algebraic integer.

**modulus** : int, None, optional

If not None, all representations will be reduced w.r.t. this.

sympy.polys.numberfields.utilities.**coeff\_search**(*m*, *R*)

Generate coefficients for searching through polynomials.

### Parameters

**m** : int

Length of coeff list.

**R** : int

Initial max abs val for coeffs (will increase as search proceeds).

**Returns**

generator

Infinite generator of lists of coefficients.

**Explanation**

Lead coeff is always non-negative. Explore all combinations with coeffs bounded in absolute value before increasing the bound. Skip the all-zero list, and skip any repeats. See examples.

**Examples**

```
>>> from sympy.polys.numberfields.utilities import coeff_search
>>> cs = coeff_search(2, 1)
>>> C = [next(cs) for i in range(13)]
>>> print(C)
[[1, 1], [1, 0], [1, -1], [0, 1], [2, 2], [2, 1], [2, 0], [2, -1], [2, -
-2],
 [1, 2], [1, -2], [0, 2], [3, 3]]
```

`sympy.polys.numberfields.utilities.supplement_a_subspace(M)`

Extend a basis for a subspace to a basis for the whole space.

**Parameters**

**M** : *DomainMatrix* (page 2671)

The columns give the basis for the subspace.

**Returns**

*DomainMatrix* (page 2671)

This matrix is invertible and its first  $r$  columns equal  $M$ .

**Raises**

**DMRankError**

If  $M$  was not of maximal rank.

**Explanation**

Given an  $n \times r$  matrix  $M$  of rank  $r$  (so  $r \leq n$ ), this function computes an invertible  $n \times n$  matrix  $B$  such that the first  $r$  columns of  $B$  equal  $M$ .

This operation can be interpreted as a way of extending a basis for a subspace, to give a basis for the whole space.

To be precise, suppose you have an  $n$ -dimensional vector space  $V$ , with basis  $\{v_1, v_2, \dots, v_n\}$ , and an  $r$ -dimensional subspace  $W$  of  $V$ , spanned by a basis  $\{w_1, w_2, \dots, w_r\}$ , where the  $w_j$  are given as linear combinations of the  $v_i$ . If the columns of  $M$  represent

the  $w_j$  as such linear combinations, then the columns of the matrix  $B$  computed by this function give a new basis  $\{u_1, u_2, \dots, u_n\}$  for  $V$ , again relative to the  $\{v_i\}$  basis, and such that  $u_j = w_j$  for  $1 \leq j \leq r$ .

## Examples

Note: The function works in terms of columns, so in these examples we print matrix transposes in order to make the columns easier to inspect.

```
>>> from sympy.polys.matrices import DM
>>> from sympy import QQ, FF
>>> from sympy.polys.numberfields.utilities import supplement_a_subspace
>>> M = DM([[1, 7, 0], [2, 3, 4]], QQ).transpose()
>>> print(supplement_a_subspace(M).to_Matrix().transpose())
Matrix([[1, 7, 0], [2, 3, 4], [1, 0, 0]])
```

```
>>> M2 = M.convert_to(FF(7))
>>> print(M2.to_Matrix().transpose())
Matrix([[1, 0, 0], [2, 3, -3]])
>>> print(supplement_a_subspace(M2).to_Matrix().transpose())
Matrix([[1, 0, 0], [2, 3, -3], [0, 1, 0]])
```

## References

[R718]

`sympy.polys.numberfields.utilities.isolate(alg, eps=None, fast=False)`

Find a rational isolating interval for a real algebraic number.

### Parameters

**alg** : str, int, *Expr* (page 947)

The algebraic number to be isolated. Must be a real number, to use this particular function. However, see also *Poly.intervals()* (page 2398), which isolates complex roots when you pass *all*=True.

**eps** : positive element of *QQ* (page 2529), None, optional (default=None)

Precision to be passed to *Poly.refine\_root()* (page 2412)

**fast** : boolean, optional (default=False)

Say whether fast refinement procedure should be used. (Will be passed to *Poly.refine\_root()* (page 2412).)

### Returns

Pair of rational numbers defining an isolating interval for the given algebraic number.

## Examples

```
>>> from sympy import isolate, sqrt, Rational
>>> print(isolate(sqrt(2)))
(1, 2)
>>> print(isolate(sqrt(2), eps=Rational(1, 100)))
(24/17, 17/12)
```

### See also:

*Poly.intervals* (page 2398)

## Category Theory

### Introduction

The category theory module for SymPy will allow manipulating diagrams within a single category, including drawing them in TikZ and deciding whether they are commutative or not.

The general reference work this module tries to follow is

The latest version of this book should be available for free download from

[katmat.math.uni-bremen.de/acc/acc.pdf](http://katmat.math.uni-bremen.de/acc/acc.pdf)

The module is still in its pre-embryonic stage.

### Base Class Reference

This section lists the classes which implement some of the basic notions in category theory: objects, morphisms, categories, and diagrams.

**class** sympy.categories.**Object**(*name*, *\*\*assumptions*)

The base class for any kind of object in an abstract category.

### Explanation

While technically any instance of *Basic* (page 927) will do, this class is the recommended way to create abstract objects in abstract categories.

**class** sympy.categories.**Morphism**(*domain*, *codomain*)

The base class for any morphism in an abstract category.

## Explanation

In abstract categories, a morphism is an arrow between two category objects. The object where the arrow starts is called the domain, while the object where the arrow ends is called the codomain.

Two morphisms between the same pair of objects are considered to be the same morphisms. To distinguish between morphisms between the same objects use *NamedMorphism* (page 2744).

It is prohibited to instantiate this class. Use one of the derived classes instead.

### See also:

*IdentityMorphism* (page 2746), *NamedMorphism* (page 2744), *CompositeMorphism* (page 2744)

### property codomain

Returns the codomain of the morphism.

## Examples

```
>>> from sympy.categories import Object, NamedMorphism
>>> A = Object("A")
>>> B = Object("B")
>>> f = NamedMorphism(A, B, "f")
>>> f.codomain
Object("B")
```

### compose(*other*)

Composes self with the supplied morphism.

The order of elements in the composition is the usual order, i.e., to construct  $g \circ f$  use `g.compose(f)`.

## Examples

```
>>> from sympy.categories import Object, NamedMorphism
>>> A = Object("A")
>>> B = Object("B")
>>> C = Object("C")
>>> f = NamedMorphism(A, B, "f")
>>> g = NamedMorphism(B, C, "g")
>>> g * f
CompositeMorphism((NamedMorphism(Object("A"), Object("B"), "f"),
NamedMorphism(Object("B"), Object("C"), "g")))
>>> (g * f).domain
Object("A")
>>> (g * f).codomain
Object("C")
```

### property domain

Returns the domain of the morphism.

### Examples

```
>>> from sympy.categories import Object, NamedMorphism
>>> A = Object("A")
>>> B = Object("B")
>>> f = NamedMorphism(A, B, "f")
>>> f.domain
Object("A")
```

**class** sympy.categories.NamedMorphism(*domain, codomain, name*)

Represents a morphism which has a name.

### Explanation

Names are used to distinguish between morphisms which have the same domain and codomain: two named morphisms are equal if they have the same domains, codomains, and names.

### Examples

```
>>> from sympy.categories import Object, NamedMorphism
>>> A = Object("A")
>>> B = Object("B")
>>> f = NamedMorphism(A, B, "f")
>>> f
NamedMorphism(Object("A"), Object("B"), "f")
>>> f.name
'f'
```

**See also:**

[\*Morphism\*](#) (page 2742)

**property name**

Returns the name of the morphism.

### Examples

```
>>> from sympy.categories import Object, NamedMorphism
>>> A = Object("A")
>>> B = Object("B")
>>> f = NamedMorphism(A, B, "f")
>>> f.name
'f'
```

**class** sympy.categories.CompositeMorphism(*\*components*)

Represents a morphism which is a composition of other morphisms.

## Explanation

Two composite morphisms are equal if the morphisms they were obtained from (components) are the same and were listed in the same order.

The arguments to the constructor for this class should be listed in diagram order: to obtain the composition  $g \circ f$  from the instances of *Morphism* (page 2742) *g* and *f* use `CompositeMorphism(f, g)`.

## Examples

```
>>> from sympy.categories import Object, NamedMorphism, CompositeMorphism
>>> A = Object("A")
>>> B = Object("B")
>>> C = Object("C")
>>> f = NamedMorphism(A, B, "f")
>>> g = NamedMorphism(B, C, "g")
>>> g * f
CompositeMorphism((NamedMorphism(Object("A"), Object("B"), "f"),
NamedMorphism(Object("B"), Object("C"), "g")))
>>> CompositeMorphism(f, g) == g * f
True
```

### property codomain

Returns the codomain of this composite morphism.

The codomain of the composite morphism is the codomain of its last component.

## Examples

```
>>> from sympy.categories import Object, NamedMorphism
>>> A = Object("A")
>>> B = Object("B")
>>> C = Object("C")
>>> f = NamedMorphism(A, B, "f")
>>> g = NamedMorphism(B, C, "g")
>>> (g * f).codomain
Object("C")
```

### property components

Returns the components of this composite morphism.

### Examples

```
>>> from sympy.categories import Object, NamedMorphism
>>> A = Object("A")
>>> B = Object("B")
>>> C = Object("C")
>>> f = NamedMorphism(A, B, "f")
>>> g = NamedMorphism(B, C, "g")
>>> (g * f).components
(NamedMorphism(Object("A"), Object("B"), "f"),
 NamedMorphism(Object("B"), Object("C"), "g"))
```

### property domain

Returns the domain of this composite morphism.

The domain of the composite morphism is the domain of its first component.

### Examples

```
>>> from sympy.categories import Object, NamedMorphism
>>> A = Object("A")
>>> B = Object("B")
>>> C = Object("C")
>>> f = NamedMorphism(A, B, "f")
>>> g = NamedMorphism(B, C, "g")
>>> (g * f).domain
Object("A")
```

### flatten(*new\_name*)

Forgets the composite structure of this morphism.

### Explanation

If *new\_name* is not empty, returns a [\*NamedMorphism\*](#) (page 2744) with the supplied name, otherwise returns a [\*Morphism\*](#) (page 2742). In both cases the domain of the new morphism is the domain of this composite morphism and the codomain of the new morphism is the codomain of this composite morphism.

### Examples

```
>>> from sympy.categories import Object, NamedMorphism
>>> A = Object("A")
>>> B = Object("B")
>>> C = Object("C")
>>> f = NamedMorphism(A, B, "f")
>>> g = NamedMorphism(B, C, "g")
>>> (g * f).flatten("h")
NamedMorphism(Object("A"), Object("C"), "h")
```

**class** sympy.categories.**IdentityMorphism**(*domain*)

Represents an identity morphism.

### Explanation

An identity morphism is a morphism with equal domain and codomain, which acts as an identity with respect to composition.

### Examples

```
>>> from sympy.categories import Object, NamedMorphism, IdentityMorphism
>>> A = Object("A")
>>> B = Object("B")
>>> f = NamedMorphism(A, B, "f")
>>> id_A = IdentityMorphism(A)
>>> id_B = IdentityMorphism(B)
>>> f * id_A == f
True
>>> id_B * f == f
True
```

**See also:**

[Morphism](#) (page 2742)

**class** sympy.categories.**Category**(*name*, *objects*=*EmptySet*,  
                                  *commutative\_diagrams*=*EmptySet*)

An (abstract) category.

### Explanation

A category [JoyOfCats] is a quadruple  $K = (O, \text{hom}, id, \circ)$  consisting of

- a (set-theoretical) class  $O$ , whose members are called  $K$ -objects,
- for each pair  $(A, B)$  of  $K$ -objects, a set  $\text{hom}(A, B)$  whose members are called  $K$ -morphisms from  $A$  to  $B$ ,
- for a each  $K$ -object  $A$ , a morphism  $id : A \rightarrow A$ , called the  $K$ -identity of  $A$ ,
- a composition law  $\circ$  associating with every  $K$ -morphisms  $f : A \rightarrow B$  and  $g : B \rightarrow C$  a  $K$ -morphism  $g \circ f : A \rightarrow C$ , called the composite of  $f$  and  $g$ .

Composition is associative,  $K$ -identities are identities with respect to composition, and the sets  $\text{hom}(A, B)$  are pairwise disjoint.

This class knows nothing about its objects and morphisms. Concrete cases of (abstract) categories should be implemented as classes derived from this one.

Certain instances of [Diagram](#) (page 2749) can be asserted to be commutative in a [Category](#) (page 2747) by supplying the argument `commutative_diagrams` in the constructor.

## Examples

```
>>> from sympy.categories import Object, NamedMorphism, Diagram, Category
>>> from sympy import FiniteSet
>>> A = Object("A")
>>> B = Object("B")
>>> C = Object("C")
>>> f = NamedMorphism(A, B, "f")
>>> g = NamedMorphism(B, C, "g")
>>> d = Diagram([f, g])
>>> K = Category("K", commutative_diagrams=[d])
>>> K.commutative_diagrams == FiniteSet(d)
True
```

### See also:

[Diagram](#) (page 2749)

### property `commutative_diagrams`

Returns the [FiniteSet](#) (page 1197) of diagrams which are known to be commutative in this category.

## Examples

```
>>> from sympy.categories import Object, NamedMorphism, Diagram, Category
>>> from sympy import FiniteSet
>>> A = Object("A")
>>> B = Object("B")
>>> C = Object("C")
>>> f = NamedMorphism(A, B, "f")
>>> g = NamedMorphism(B, C, "g")
>>> d = Diagram([f, g])
>>> K = Category("K", commutative_diagrams=[d])
>>> K.commutative_diagrams == FiniteSet(d)
True
```

### property `name`

Returns the name of this category.

## Examples

```
>>> from sympy.categories import Category
>>> K = Category("K")
>>> K.name
'K'
```

### property `objects`

Returns the class of objects of this category.

## Examples

```
>>> from sympy.categories import Object, Category
>>> from sympy import FiniteSet
>>> A = Object("A")
>>> B = Object("B")
>>> K = Category("K", FiniteSet(A, B))
>>> K.objects
Class({Object("A"), Object("B")})
```

**class** sympy.categories.**Diagram**(\*args)

Represents a diagram in a certain category.

## Explanation

Informally, a diagram is a collection of objects of a category and certain morphisms between them. A diagram is still a monoid with respect to morphism composition; i.e., identity morphisms, as well as all composites of morphisms included in the diagram belong to the diagram. For a more formal approach to this notion see [Pare1970].

The components of composite morphisms are also added to the diagram. No properties are assigned to such morphisms by default.

A commutative diagram is often accompanied by a statement of the following kind: “if such morphisms with such properties exist, then such morphisms which such properties exist and the diagram is commutative”. To represent this, an instance of *Diagram* (page 2749) includes a collection of morphisms which are the premises and another collection of conclusions. *premises* and *conclusions* associate morphisms belonging to the corresponding categories with the *FiniteSet* (page 1197)’s of their properties.

The set of properties of a composite morphism is the intersection of the sets of properties of its components. The domain and codomain of a conclusion morphism should be among the domains and codomains of the morphisms listed as the premises of a diagram.

No checks are carried out of whether the supplied object and morphisms do belong to one and the same category.

## Examples

```
>>> from sympy.categories import Object, NamedMorphism, Diagram
>>> from sympy import pprint, default_sort_key
>>> A = Object("A")
>>> B = Object("B")
>>> C = Object("C")
>>> f = NamedMorphism(A, B, "f")
>>> g = NamedMorphism(B, C, "g")
>>> d = Diagram([f, g])
>>> premises_keys = sorted(d.premises.keys(), key=default_sort_key)
>>> pprint(premises_keys, use_unicode=False)
[g*f:A-->C, id:A-->A, id:B-->B, id:C-->C, f:A-->B, g:B-->C]
>>> pprint(d.premises, use_unicode=False)
{g*f:A-->C: EmptySet, id:A-->A: EmptySet, id:B-->B: EmptySet, id:C-->C: }
```

(continues on next page)

(continued from previous page)

```

↳ EmptySet
et, f:A-->B: EmptySet, g:B-->C: EmptySet}
>>> d = Diagram([f, g], {g * f: "unique"})
>>> pprint(d.conclusions, use_unicode=False)
{g*f:A-->C: {unique}}

```

## References

[Pare1970] B. Pareigis: Categories and functors. Academic Press, 1970.

### property conclusions

Returns the conclusions of this diagram.

### Examples

```

>>> from sympy.categories import Object, NamedMorphism
>>> from sympy.categories import IdentityMorphism, Diagram
>>> from sympy import FiniteSet
>>> A = Object("A")
>>> B = Object("B")
>>> C = Object("C")
>>> f = NamedMorphism(A, B, "f")
>>> g = NamedMorphism(B, C, "g")
>>> d = Diagram([f, g])
>>> IdentityMorphism(A) in d.premises.keys()
True
>>> g * f in d.premises.keys()
True
>>> d = Diagram([f, g], {g * f: "unique"})
>>> d.conclusions[g * f] == FiniteSet("unique")
True

```

### hom(A, B)

Returns a 2-tuple of sets of morphisms between objects A and B: one set of morphisms listed as premises, and the other set of morphisms listed as conclusions.

### Examples

```

>>> from sympy.categories import Object, NamedMorphism, Diagram
>>> from sympy import pretty
>>> A = Object("A")
>>> B = Object("B")
>>> C = Object("C")
>>> f = NamedMorphism(A, B, "f")
>>> g = NamedMorphism(B, C, "g")
>>> d = Diagram([f, g], {g * f: "unique"})
>>> print(pretty(d.hom(A, C), use_unicode=False))
({g*f:A-->C}, {g*f:A-->C})

```

**See also:**

[Object](#) (page 2742), [Morphism](#) (page 2742)

**is\_subdiagram**(*diagram*)

Checks whether *diagram* is a subdiagram of *self*. Diagram  $D'$  is a subdiagram of  $D$  if all premises (conclusions) of  $D'$  are contained in the premises (conclusions) of  $D$ . The morphisms contained both in  $D'$  and  $D$  should have the same properties for  $D'$  to be a subdiagram of  $D$ .

**Examples**

```
>>> from sympy.categories import Object, NamedMorphism, Diagram
>>> A = Object("A")
>>> B = Object("B")
>>> C = Object("C")
>>> f = NamedMorphism(A, B, "f")
>>> g = NamedMorphism(B, C, "g")
>>> d = Diagram([f, g], {g * f: "unique"})
>>> d1 = Diagram([f])
>>> d.is_subdiagram(d1)
True
>>> d1.is_subdiagram(d)
False
```

**property objects**

Returns the [FiniteSet](#) (page 1197) of objects that appear in this diagram.

**Examples**

```
>>> from sympy.categories import Object, NamedMorphism, Diagram
>>> A = Object("A")
>>> B = Object("B")
>>> C = Object("C")
>>> f = NamedMorphism(A, B, "f")
>>> g = NamedMorphism(B, C, "g")
>>> d = Diagram([f, g])
>>> d.objects
{Object("A"), Object("B"), Object("C")}
```

**property premises**

Returns the premises of this diagram.

### Examples

```
>>> from sympy.categories import Object, NamedMorphism
>>> from sympy.categories import IdentityMorphism, Diagram
>>> from sympy import pretty
>>> A = Object("A")
>>> B = Object("B")
>>> f = NamedMorphism(A, B, "f")
>>> id_A = IdentityMorphism(A)
>>> id_B = IdentityMorphism(B)
>>> d = Diagram([f])
>>> print(pretty(d.premises, use_unicode=False))
{id:A-->A: EmptySet, id:B-->B: EmptySet, f:A-->B: EmptySet}
```

#### `subdiagram_from_objects(objects)`

If `objects` is a subset of the objects of `self`, returns a diagram which has as premises all those premises of `self` which have a domains and codomains in `objects`, likewise for conclusions. Properties are preserved.

### Examples

```
>>> from sympy.categories import Object, NamedMorphism, Diagram
>>> from sympy import FiniteSet
>>> A = Object("A")
>>> B = Object("B")
>>> C = Object("C")
>>> f = NamedMorphism(A, B, "f")
>>> g = NamedMorphism(B, C, "g")
>>> d = Diagram([f, g], {f: "unique", g*f: "veryunique"})
>>> d1 = d.subdiagram_from_objects(FiniteSet(A, B))
>>> d1 == Diagram([f], {f: "unique"})
True
```

### Diagram Drawing

This section lists the classes which allow automatic drawing of diagrams.

**class** `sympy.categories.diagram_drawing.DiagramGrid`(*diagram*, *groups=None*,  
\*\**hints*)

Constructs and holds the fitting of the diagram into a grid.

## Explanation

The mission of this class is to analyse the structure of the supplied diagram and to place its objects on a grid such that, when the objects and the morphisms are actually drawn, the diagram would be “readable”, in the sense that there will not be many intersections of morphisms. This class does not perform any actual drawing. It does strive nevertheless to offer sufficient metadata to draw a diagram.

Consider the following simple diagram.

```
>>> from sympy.categories import Object, NamedMorphism
>>> from sympy.categories import Diagram, DiagramGrid
>>> from sympy import pprint
>>> A = Object("A")
>>> B = Object("B")
>>> C = Object("C")
>>> f = NamedMorphism(A, B, "f")
>>> g = NamedMorphism(B, C, "g")
>>> diagram = Diagram([f, g])
```

The simplest way to have a diagram laid out is the following:

```
>>> grid = DiagramGrid(diagram)
>>> (grid.width, grid.height)
(2, 2)
>>> pprint(grid)
A B
 C
```

Sometimes one sees the diagram as consisting of logical groups. One can advise `DiagramGrid` as to such groups by employing the `groups` keyword argument.

Consider the following diagram:

```
>>> D = Object("D")
>>> f = NamedMorphism(A, B, "f")
>>> g = NamedMorphism(B, C, "g")
>>> h = NamedMorphism(D, A, "h")
>>> k = NamedMorphism(D, B, "k")
>>> diagram = Diagram([f, g, h, k])
```

Lay it out with generic layout:

```
>>> grid = DiagramGrid(diagram)
>>> pprint(grid)
A B D
 C
```

Now, we can group the objects *A* and *D* to have them near one another:

```
>>> grid = DiagramGrid(diagram, groups=[[A, D], B, C])
>>> pprint(grid)
B C
```

(continues on next page)

(continued from previous page)

```
A D
```

Note how the positioning of the other objects changes.

Further indications can be supplied to the constructor of *DiagramGrid* (page 2752) using keyword arguments. The currently supported hints are explained in the following paragraphs.

*DiagramGrid* (page 2752) does not automatically guess which layout would suit the supplied diagram better. Consider, for example, the following linear diagram:

```
>>> E = Object("E")
>>> f = NamedMorphism(A, B, "f")
>>> g = NamedMorphism(B, C, "g")
>>> h = NamedMorphism(C, D, "h")
>>> i = NamedMorphism(D, E, "i")
>>> diagram = Diagram([f, g, h, i])
```

When laid out with the generic layout, it does not get to look linear:

```
>>> grid = DiagramGrid(diagram)
>>> pprint(grid)
A B
 C D
 E
```

To get it laid out in a line, use `layout="sequential"`:

```
>>> grid = DiagramGrid(diagram, layout="sequential")
>>> pprint(grid)
A B C D E
```

One may sometimes need to transpose the resulting layout. While this can always be done by hand, *DiagramGrid* (page 2752) provides a hint for that purpose:

```
>>> grid = DiagramGrid(diagram, layout="sequential", transpose=True)
>>> pprint(grid)
A
B
C
D
E
```

Separate hints can also be provided for each group. For an example, refer to `tests/test_drawing.py`, and see the different ways in which the five lemma [FiveLemma] can be laid out.

**See also:**[Diagram](#) (page 2749)**References**[\[FiveLemma\]](#)**property height**

Returns the number of rows in this diagram layout.

**Examples**

```

>>> from sympy.categories import Object, NamedMorphism
>>> from sympy.categories import Diagram, DiagramGrid
>>> A = Object("A")
>>> B = Object("B")
>>> C = Object("C")
>>> f = NamedMorphism(A, B, "f")
>>> g = NamedMorphism(B, C, "g")
>>> diagram = Diagram([f, g])
>>> grid = DiagramGrid(diagram)
>>> grid.height
2

```

**property morphisms**

Returns those morphisms (and their properties) which are sufficiently meaningful to be drawn.

**Examples**

```

>>> from sympy.categories import Object, NamedMorphism
>>> from sympy.categories import Diagram, DiagramGrid
>>> A = Object("A")
>>> B = Object("B")
>>> C = Object("C")
>>> f = NamedMorphism(A, B, "f")
>>> g = NamedMorphism(B, C, "g")
>>> diagram = Diagram([f, g])
>>> grid = DiagramGrid(diagram)
>>> grid.morphisms
{NamedMorphism(Object("A"), Object("B"), "f"): EmptySet,
 NamedMorphism(Object("B"), Object("C"), "g"): EmptySet}

```

**property width**

Returns the number of columns in this diagram layout.

## Examples

```
>>> from sympy.categories import Object, NamedMorphism
>>> from sympy.categories import Diagram, DiagramGrid
>>> A = Object("A")
>>> B = Object("B")
>>> C = Object("C")
>>> f = NamedMorphism(A, B, "f")
>>> g = NamedMorphism(B, C, "g")
>>> diagram = Diagram([f, g])
>>> grid = DiagramGrid(diagram)
>>> grid.width
2
```

```
class sympy.categories.diagram_drawing.ArrowStringDescription(unit, curving,
 curving_amount,
 looping_start,
 looping_end, horizontal_direction,
 vertical_direction,
 label_position,
 label)
```

Stores the information necessary for producing an Xy-pic description of an arrow.

The principal goal of this class is to abstract away the string representation of an arrow and to also provide the functionality to produce the actual Xy-pic string.

`unit` sets the unit which will be used to specify the amount of curving and other distances. `horizontal_direction` should be a string of "r" or "l" specifying the horizontal offset of the target cell of the arrow relatively to the current one. `vertical_direction` should specify the vertical offset using a series of either "d" or "u". `label_position` should be either "^", "\_", or "|" to specify that the label should be positioned above the arrow, below the arrow or just over the arrow, in a break. Note that the notions "above" and "below" are relative to arrow direction. `label` stores the morphism label.

This works as follows (disregard the yet unexplained arguments):

```
>>> from sympy.categories.diagram_drawing import ArrowStringDescription
>>> astr = ArrowStringDescription(
... unit="mm", curving=None, curving_amount=None,
... looping_start=None, looping_end=None, horizontal_direction="d",
... vertical_direction="r", label_position="_", label="f")
>>> print(str(astr))
\ar[dr]_{f}
```

`curving` should be one of "^", "\_" to specify in which direction the arrow is going to curve. `curving_amount` is a number describing how many unit's the morphism is going to curve:

```
>>> astr = ArrowStringDescription(
... unit="mm", curving="^", curving_amount=12,
... looping_start=None, looping_end=None, horizontal_direction="d",
... vertical_direction="r", label_position="_", label="f")
>>> print(str(astr))
\ar@/^12mm/[dr]_{f}
```

looping\_start and looping\_end are currently only used for loop morphisms, those which have the same domain and codomain. These two attributes should store a valid Xy-pic direction and specify, correspondingly, the direction the arrow gets out into and the direction the arrow gets back from:

```
>>> astr = ArrowStringDescription(
... unit="mm", curving=None, curving_amount=None,
... looping_start="u", looping_end="l", horizontal_direction="",
... vertical_direction="", label_position="_", label="f")
>>> print(str(astr))
\ar@(u,l)[]_{f}
```

label\_displacement controls how far the arrow label is from the ends of the arrow. For example, to position the arrow label near the arrow head, use ">":

```
>>> astr = ArrowStringDescription(
... unit="mm", curving="^", curving_amount=12,
... looping_start=None, looping_end=None, horizontal_direction="d",
... vertical_direction="r", label_position="_", label="f")
>>> astr.label_displacement = ">"
>>> print(str(astr))
\ar@/^12mm/[dr]_{>f}
```

Finally, arrow\_style is used to specify the arrow style. To get a dashed arrow, for example, use "{->}" as arrow style:

```
>>> astr = ArrowStringDescription(
... unit="mm", curving="^", curving_amount=12,
... looping_start=None, looping_end=None, horizontal_direction="d",
... vertical_direction="r", label_position="_", label="f")
>>> astr.arrow_style = "{->}"
>>> print(str(astr))
\ar@/^12mm/@{->}[dr]_{f}
```

## Notes

Instances of *ArrowStringDescription* (page 2756) will be constructed by *XypicDiagramDrawer* (page 2758) and provided for further use in formatters. The user is not expected to construct instances of *ArrowStringDescription* (page 2756) themselves.

To be able to properly utilise this class, the reader is encouraged to checkout the Xy-pic user guide, available at [Xypic].

*XypicDiagramDrawer* (page 2758)

## References

[Xypic]

**class** sympy.categories.diagram\_drawing.XypicDiagramDrawer

Given a [Diagram](#) (page 2749) and the corresponding [DiagramGrid](#) (page 2752), produces the Xy-pic representation of the diagram.

The most important method in this class is `draw`. Consider the following triangle diagram:

```
>>> from sympy.categories import Object, NamedMorphism, Diagram
>>> from sympy.categories import DiagramGrid, XypicDiagramDrawer
>>> A = Object("A")
>>> B = Object("B")
>>> C = Object("C")
>>> f = NamedMorphism(A, B, "f")
>>> g = NamedMorphism(B, C, "g")
>>> diagram = Diagram([f, g], {g * f: "unique"})
```

To draw this diagram, its objects need to be laid out with a [DiagramGrid](#) (page 2752):

```
>>> grid = DiagramGrid(diagram)
```

Finally, the drawing:

```
>>> drawer = XypicDiagramDrawer()
>>> print(drawer.draw(diagram, grid))
\xymatrix{
A \ar[d]_{g\circ f} \ar[r]^{f} & B \ar[ld]^{g} \\
C & \\
}
```

For further details see the docstring of this method.

To control the appearance of the arrows, formatters are used. The dictionary `arrow_formatters` maps morphisms to formatter functions. A formatter accepts an [ArrowStringDescription](#) (page 2756) and is allowed to modify any of the arrow properties exposed thereby. For example, to have all morphisms with the property `unique` appear as dashed arrows, and to have their names prepended with  $\exists!$ , the following should be done:

```
>>> def formatter(astr):
... astr.label = r"\exists !" + astr.label
... astr.arrow_style = "{-->}"
>>> drawer.arrow_formatters["unique"] = formatter
>>> print(drawer.draw(diagram, grid))
\xymatrix{
A \ar@{->}[d]_{\exists !g\circ f} \ar[r]^{f} & B \ar[ld]^{g} \\
C & \\
}
```

To modify the appearance of all arrows in the diagram, set `default_arrow_formatter`. For example, to place all morphism labels a little bit farther from the arrow head so that they look more centred, do as follows:

```
>>> def default_formatter(astr):
... astr.label_displacement = "(0.45)"
>>> drawer.default_arrow_formatter = default_formatter
>>> print(drawer.draw(diagram, grid))
\xymatrix{
A \ar@{->}[d]_(0.45){\exists !g\circ f} \ar[r]^(0.45){f} & B \ar[l]^(0.
\rightarrow 45){g} \\
C &
}
```

In some diagrams some morphisms are drawn as curved arrows. Consider the following diagram:

```
>>> D = Object("D")
>>> E = Object("E")
>>> h = NamedMorphism(D, A, "h")
>>> k = NamedMorphism(D, B, "k")
>>> diagram = Diagram([f, g, h, k])
>>> grid = DiagramGrid(diagram)
>>> drawer = XypicDiagramDrawer()
>>> print(drawer.draw(diagram, grid))
\xymatrix{
A \ar[r]_f & B \ar[d]^g & D \ar[l]^{k} \ar@/_3mm/[ll]_h \\
& C &
}
```

To control how far the morphisms are curved by default, one can use the `unit` and `default_curving_amount` attributes:

```
>>> drawer.unit = "cm"
>>> drawer.default_curving_amount = 1
>>> print(drawer.draw(diagram, grid))
\xymatrix{
A \ar[r]_f & B \ar[d]^g & D \ar[l]^{k} \ar@/_1cm/[ll]_h \\
& C &
}
```

In some diagrams, there are multiple curved morphisms between the same two objects. To control by how much the curving changes between two such successive morphisms, use `default_curving_step`:

```
>>> drawer.default_curving_step = 1
>>> h1 = NamedMorphism(A, D, "h1")
>>> diagram = Diagram([f, g, h, k, h1])
>>> grid = DiagramGrid(diagram)
>>> print(drawer.draw(diagram, grid))
\xymatrix{
A \ar[r]_f \ar@/^1cm/[rr]^{h_1} & B \ar[d]^g & D \ar[l]^{k} \ar@/_
\rightarrow 2cm/[ll]_h \\
& C &
}
```

The default value of `default_curving_step` is 4 units.

See also:

[draw](#) (page 2760), [ArrowStringDescription](#) (page 2756)

**draw**(*diagram*, *grid*, *masked=None*, *diagram\_format=""*)

Returns the Xy-pic representation of diagram laid out in grid.

Consider the following simple triangle diagram.

```
>>> from sympy.categories import Object, NamedMorphism, Diagram
>>> from sympy.categories import DiagramGrid, XypicDiagramDrawer
>>> A = Object("A")
>>> B = Object("B")
>>> C = Object("C")
>>> f = NamedMorphism(A, B, "f")
>>> g = NamedMorphism(B, C, "g")
>>> diagram = Diagram([f, g], {g * f: "unique"})
```

To draw this diagram, its objects need to be laid out with a [DiagramGrid](#) (page 2752):

```
>>> grid = DiagramGrid(diagram)
```

Finally, the drawing:

```
>>> drawer = XypicDiagramDrawer()
>>> print(drawer.draw(diagram, grid))
\xymatrix{
A \ar[d]_{g\circ f} \ar[r]^{f} & B \ar[ld]^{g} \\
C & \\
}
```

The argument *masked* can be used to skip morphisms in the presentation of the diagram:

```
>>> print(drawer.draw(diagram, grid, masked=[g * f]))
\xymatrix{
A \ar[r]^{f} & B \ar[ld]^{g} \\
C & \\
}
```

Finally, the *diagram\_format* argument can be used to specify the format string of the diagram. For example, to increase the spacing by 1 cm, proceeding as follows:

```
>>> print(drawer.draw(diagram, grid, diagram_format="@+1cm"))
\xymatrix@+1cm{
A \ar[d]_{g\circ f} \ar[r]^{f} & B \ar[ld]^{g} \\
C & \\
}
```

`sympy.categories.diagram_drawing.xypic_draw_diagram`(*diagram*, *masked=None*,  
*diagram\_format=""*,  
*groups=None*, *\*\*hints*)

Provides a shortcut combining [DiagramGrid](#) (page 2752) and [XypicDiagramDrawer](#) (page 2758). Returns an Xy-pic presentation of diagram. The argument *masked* is a list of morphisms which will be not be drawn. The argument *diagram\_format* is the

format string inserted after “xymatrix”. groups should be a set of logical groups. The hints will be passed directly to the constructor of *DiagramGrid* (page 2752).

For more information about the arguments, see the docstrings of *DiagramGrid* (page 2752) and *XypicDiagramDrawer*.draw.

### Examples

```
>>> from sympy.categories import Object, NamedMorphism, Diagram
>>> from sympy.categories import xypic_draw_diagram
>>> A = Object("A")
>>> B = Object("B")
>>> C = Object("C")
>>> f = NamedMorphism(A, B, "f")
>>> g = NamedMorphism(B, C, "g")
>>> diagram = Diagram([f, g], {g * f: "unique"})
>>> print(xypic_draw_diagram(diagram))
\xymatrix{
A \ar[d]_{g \circ f} \ar[r]^{f} & B \ar[l]^{g} \\
C & \\
}
```

#### See also:

*XypicDiagramDrawer* (page 2758), *DiagramGrid* (page 2752)

```
sympy.categories.diagram_drawing.preview_diagram(diagram, masked=None,
 diagram_format="",
 groups=None, output='png',
 viewer=None, euler=True,
 **hints)
```

Combines the functionality of *xypic\_draw\_diagram* and *sympy.printing.preview*. The arguments *masked*, *diagram\_format*, *groups*, and *hints* are passed to *xypic\_draw\_diagram*, while *output*, *viewer*, and *euler* are passed to *preview*.

### Examples

```
>>> from sympy.categories import Object, NamedMorphism, Diagram
>>> from sympy.categories import preview_diagram
>>> A = Object("A")
>>> B = Object("B")
>>> C = Object("C")
>>> f = NamedMorphism(A, B, "f")
>>> g = NamedMorphism(B, C, "g")
>>> d = Diagram([f, g], {g * f: "unique"})
>>> preview_diagram(d)
```

*XypicDiagramDrawer* (page 2758)

## Cryptography

**Warning:** This module is intended for educational purposes only. Do not use the functions in this module for real cryptographic applications. If you wish to encrypt real data, we recommend using something like the [cryptography](#) module.

Encryption is the process of hiding a message and a cipher is a means of doing so. Included in this module are both block and stream ciphers:

- Shift cipher
- Affine cipher
- substitution ciphers
- Vigenere’s cipher
- Hill’s cipher
- Bifid ciphers
- RSA
- Kid RSA
- linear-feedback shift registers (for stream ciphers)
- ElGamal encryption

In a *substitution cipher* “units” (not necessarily single characters) of plaintext are replaced with ciphertext according to a regular system.

A *transposition cipher* is a method of encryption by which the positions held by “units” of plaintext are replaced by a permutation of the plaintext. That is, the order of the units is changed using a bijective function on the position of the characters to perform the encryption.

A *monoalphabetic cipher* uses fixed substitution over the entire message, whereas a *polyalphabetic cipher* uses a number of substitutions at different times in the message.

`sympy.crypto.crypto.AZ(s=None)`

Return the letters of `s` in uppercase. In case more than one string is passed, each of them will be processed and a list of upper case strings will be returned.

### Examples

```
>>> from sympy.crypto.crypto import AZ
>>> AZ('Hello, world!')
'HELLOWORLD'
>>> AZ('Hello, world!'.split())
['HELLO', 'WORLD']
```

### See also:

[check\\_and\\_join](#) (page 2763)

`sympy.crypto.crypto.padded_key(key, symbols)`

Return a string of the distinct characters of `symbols` with those of `key` appearing first. A `ValueError` is raised if a) there are duplicate characters in `symbols` or b) there are characters in `key` that are not in `symbols`.

### Examples

```
>>> from sympy.crypto.crypto import padded_key
>>> padded_key('PUPPY', 'OPQRSTUVWXYZ')
'PUYQIRSTVWX'
>>> padded_key('RSA', 'ARTIST')
Traceback (most recent call last):
...
ValueError: duplicate characters in symbols: T
```

`sympy.crypto.crypto.check_and_join(phrase, symbols=None, filter=None)`

Joins characters of `phrase` and if `symbols` is given, raises an error if any character in `phrase` is not in `symbols`.

#### Parameters

##### **phrase**

String or list of strings to be returned as a string.

##### **symbols**

Iterable of characters allowed in phrase.

If `symbols` is `None`, no checking is performed.

### Examples

```
>>> from sympy.crypto.crypto import check_and_join
>>> check_and_join('a phrase')
'a phrase'
>>> check_and_join('a phrase'.upper().split())
'APHRASE'
>>> check_and_join('a phrase!'.upper().split(), 'ARE', filter=True)
'ARAE'
>>> check_and_join('a phrase!'.upper().split(), 'ARE')
Traceback (most recent call last):
...
ValueError: characters in phrase but not symbols: "!HPS"
```

`sympy.crypto.crypto.cycle_list(k, n)`

Returns the elements of the list `range(n)` shifted to the left by `k` (so the list starts with `k (mod n)`).

## Examples

```
>>> from sympy.crypto.crypto import cycle_list
>>> cycle_list(3, 10)
[3, 4, 5, 6, 7, 8, 9, 0, 1, 2]
```

`sympy.crypto.crypto.encipher_shift(msg, key, symbols=None)`

Performs shift cipher encryption on plaintext msg, and returns the ciphertext.

### Parameters

**key** : int

The secret key.

**msg** : str

Plaintext of upper-case letters.

### Returns

str

Ciphertext of upper-case letters.

## Examples

```
>>> from sympy.crypto.crypto import encipher_shift, decipher_shift
>>> msg = "GONAVYBEATARMY"
>>> ct = encipher_shift(msg, 1); ct
'HPOBWZCFBUBSNZ'
```

To decipher the shifted text, change the sign of the key:

```
>>> encipher_shift(ct, -1)
'GONAVYBEATARMY'
```

There is also a convenience function that does this with the original key:

```
>>> decipher_shift(ct, 1)
'GONAVYBEATARMY'
```

## Notes

ALGORITHM:

### STEPS:

0. Number the letters of the alphabet from 0, ..., N
1. Compute from the string msg a list L1 of corresponding integers.
2. Compute from the list L1 a new list L2, given by adding  $(k \bmod 26)$  to each element in L1.
3. Compute from the list L2 a string ct of corresponding letters.

The shift cipher is also called the Caesar cipher, after Julius Caesar, who, according to Suetonius, used it with a shift of three to protect messages of military significance. Caesar's nephew Augustus reportedly used a similar cipher, but with a right shift of 1.

**See also:**

[\*decipher\\_shift\*](#) (page 2765)

## References

[R136], [R137]

`sympy.crypto.crypto.decipher_shift(msg, key, symbols=None)`

Return the text by shifting the characters of msg to the left by the amount given by key.

## Examples

```
>>> from sympy.crypto.crypto import encipher_shift, decipher_shift
>>> msg = "GONAVYBEATARMY"
>>> ct = encipher_shift(msg, 1); ct
'HPOBWZCFBUBSNZ'
```

To decipher the shifted text, change the sign of the key:

```
>>> encipher_shift(ct, -1)
'GONAVYBEATARMY'
```

Or use this function with the original key:

```
>>> decipher_shift(ct, 1)
'GONAVYBEATARMY'
```

`sympy.crypto.crypto.encipher_rot13(msg, symbols=None)`

Performs the ROT13 encryption on a given plaintext msg.

## Explanation

ROT13 is a substitution cipher which substitutes each letter in the plaintext message for the letter furthest away from it in the English alphabet.

Equivalently, it is just a Caesar (shift) cipher with a shift key of 13 (midway point of the alphabet).

**See also:**

[\*decipher\\_rot13\*](#) (page 2766), [\*encipher\\_shift\*](#) (page 2764)

## References

[R138]

`sympy.crypto.crypto.decipher_rot13(msg, symbols=None)`

Performs the ROT13 decryption on a given plaintext msg.

## Explanation

`decipher_rot13` is equivalent to `encipher_rot13` as both `decipher_shift` with a key of 13 and `encipher_shift` key with a key of 13 will return the same results. Nonetheless, `decipher_rot13` has nonetheless been explicitly defined here for consistency.

## Examples

```
>>> from sympy.crypto.crypto import encipher_rot13, decipher_rot13
>>> msg = 'GONAVYBEATARMY'
>>> ciphertext = encipher_rot13(msg);ciphertext
'TBANILORNGNEZL'
>>> decipher_rot13(ciphertext)
'GONAVYBEATARMY'
>>> encipher_rot13(msg) == decipher_rot13(msg)
True
>>> msg == decipher_rot13(ciphertext)
True
```

`sympy.crypto.crypto.encipher_affine(msg, key, symbols=None, _inverse=False)`

Performs the affine cipher encryption on plaintext msg, and returns the ciphertext.

### Parameters

**msg** : str

Characters that appear in symbols.

**a, b** : int, int

A pair integers, with  $\gcd(a, N) = 1$  (the secret key).

### symbols

String of characters (default = uppercase letters).

When no symbols are given, msg is converted to upper case letters and all other characters are ignored.

### Returns

ct

String of characters (the ciphertext message)

## Explanation

Encryption is based on the map  $x \rightarrow ax + b \pmod{N}$  where  $N$  is the number of characters in the alphabet. Decryption is based on the map  $x \rightarrow cx + d \pmod{N}$ , where  $c = a^{-1} \pmod{N}$  and  $d = -a^{-1}b \pmod{N}$ . In particular, for the map to be invertible, we need  $\gcd(a, N) = 1$  and an error will be raised if this is not true.

## Notes

ALGORITHM:

### STEPS:

0. Number the letters of the alphabet from 0, ...,  $N$
1. Compute from the string `msg` a list `L1` of corresponding integers.
2. Compute from the list `L1` a new list `L2`, given by replacing  $x$  by  $a*x + b \pmod{N}$ , for each element  $x$  in `L1`.
3. Compute from the list `L2` a string `ct` of corresponding letters.

This is a straightforward generalization of the shift cipher with the added complexity of requiring 2 characters to be deciphered in order to recover the key.

**See also:**

[`decipher\_affine`](#) (page 2767)

## References

[R139]

`sympy.crypto.crypto.decipher_affine(msg, key, symbols=None)`

Return the deciphered text that was made from the mapping,  $x \rightarrow ax + b \pmod{N}$ , where  $N$  is the number of characters in the alphabet. Deciphering is done by reciphering with a new key:  $x \rightarrow cx + d \pmod{N}$ , where  $c = a^{-1} \pmod{N}$  and  $d = -a^{-1}b \pmod{N}$ .

## Examples

```
>>> from sympy.crypto.crypto import encipher_affine, decipher_affine
>>> msg = "GO NAVY BEAT ARMY"
>>> key = (3, 1)
>>> encipher_affine(msg, key)
'TROBMVENBGBALV'
>>> decipher_affine(_, key)
'GONAVYBEATARMY'
```

**See also:**

[`encipher\_affine`](#) (page 2766)

`sympy.crypto.crypto.encipher_atbash(msg, symbols=None)`

Enciphers a given `msg` into its Atbash ciphertext and returns it.

### Explanation

Atbash is a substitution cipher originally used to encrypt the Hebrew alphabet. Atbash works on the principle of mapping each alphabet to its reverse / counterpart (i.e. a would map to z, b to y etc.)

Atbash is functionally equivalent to the affine cipher with  $a = 25$  and  $b = 25$

#### See also:

[\*decipher\\_atbash\*](#) (page 2768)

`sympy.crypto.crypto.decipher_atbash(msg, symbols=None)`

Deciphers a given msg using Atbash cipher and returns it.

### Explanation

`decipher_atbash` is functionally equivalent to `encipher_atbash`. However, it has still been added as a separate function to maintain consistency.

### Examples

```
>>> from sympy.crypto.crypto import encipher_atbash, decipher_atbash
>>> msg = 'GONAVYBEATARMY'
>>> encipher_atbash(msg)
'TLMZEBYVZGZINB'
>>> decipher_atbash(msg)
'TLMZEBYVZGZINB'
>>> encipher_atbash(msg) == decipher_atbash(msg)
True
>>> msg == encipher_atbash(encipher_atbash(msg))
True
```

#### See also:

[\*encipher\\_atbash\*](#) (page 2767)

### References

[R140]

`sympy.crypto.crypto.encipher_substitution(msg, old, new=None)`

Returns the ciphertext obtained by replacing each character that appears in `old` with the corresponding character in `new`. If `old` is a mapping, then `new` is ignored and the replacements defined by `old` are used.

## Explanation

This is a more general than the affine cipher in that the key can only be recovered by determining the mapping for each symbol. Though in practice, once a few symbols are recognized the mappings for other characters can be quickly guessed.

## Examples

```
>>> from sympy.crypto.crypto import encipher_substitution, AZ
>>> old = 'OEYAG'
>>> new = 'Q34^6'
>>> msg = AZ("go navy! beat army!")
>>> ct = encipher_substitution(msg, old, new); ct
'60N^V4B3^T^RM4'
```

To decrypt a substitution, reverse the last two arguments:

```
>>> encipher_substitution(ct, new, old)
'GONAVYBEATARMY'
```

In the special case where old and new are a permutation of order 2 (representing a transposition of characters) their order is immaterial:

```
>>> old = 'NAVY'
>>> new = 'ANYV'
>>> encipher = lambda x: encipher_substitution(x, old, new)
>>> encipher('NAVY')
'ANYV'
>>> encipher(_)
'NAVY'
```

The substitution cipher, in general, is a method whereby “units” (not necessarily single characters) of plaintext are replaced with ciphertext according to a regular system.

```
>>> ords = dict(zip('abc', ['\\%i' % ord(i) for i in 'abc']))
>>> print(encipher_substitution('abc', ords))
\97\98\99
```

## References

[R141]

`sympy.crypto.crypto.encipher_vigenere(msg, key, symbols=None)`

Performs the Vigenere cipher encryption on plaintext msg, and returns the ciphertext.

## Examples

```
>>> from sympy.crypto.crypto import encipher_vigenere, AZ
>>> key = "encrypt"
>>> msg = "meet me on monday"
>>> encipher_vigenere(msg, key)
'QRGKKTHRZQEBPR'
```

Section 1 of the Kryptos sculpture at the CIA headquarters uses this cipher and also changes the order of the alphabet [R143]. Here is the first line of that section of the sculpture:

```
>>> from sympy.crypto.crypto import decipher_vigenere, padded_key
>>> alp = padded_key('KRYPTOS', AZ())
>>> key = 'PALIMPSEST'
>>> msg = 'EMUFPHZLRFAXYUSDJKZLDKRNSHGNFIVJ'
>>> decipher_vigenere(msg, key, alp)
'BETWEENSUBTLESHADINGANDTHEABSENC'
```

## Explanation

The Vigenere cipher is named after Blaise de Vigenere, a sixteenth century diplomat and cryptographer, by a historical accident. Vigenere actually invented a different and more complicated cipher. The so-called *Vigenere cipher* was actually invented by Giovan Batista Belaso in 1553.

This cipher was used in the 1800's, for example, during the American Civil War. The Confederacy used a brass cipher disk to implement the Vigenere cipher (now on display in the NSA Museum in Fort Meade) [R142].

The Vigenere cipher is a generalization of the shift cipher. Whereas the shift cipher shifts each letter by the same amount (that amount being the key of the shift cipher) the Vigenere cipher shifts a letter by an amount determined by the key (which is a word or phrase known only to the sender and receiver).

For example, if the key was a single letter, such as "C", then the so-called Vigenere cipher is actually a shift cipher with a shift of 2 (since "C" is the 2nd letter of the alphabet, if you start counting at 0). If the key was a word with two letters, such as "CA", then the so-called Vigenere cipher will shift letters in even positions by 2 and letters in odd positions are left alone (shifted by 0, since "A" is the 0th letter, if you start counting at 0).

ALGORITHM:

INPUT:

msg: string of characters that appear in symbols (the plaintext)  
key: a string of characters that appear in symbols (the secret key)  
symbols: a string of letters defining the alphabet

OUTPUT:

ct: string of characters (the ciphertext message)

STEPS:

0. Number the letters of the alphabet from 0, ..., N

1. Compute from the string `key` a list `L1` of corresponding integers. Let `n1 = len(L1)`.
2. Compute from the string `msg` a list `L2` of corresponding integers. Let `n2 = len(L2)`.
3. Break `L2` up sequentially into sublists of size `n1`; the last sublist may be smaller than `n1`.
4. For each of these sublists `L` of `L2`, compute a new list `C` given by  $C[i] = L[i] + L1[i] \pmod{N}$  to the  $i$ -th element in the sublist, for each  $i$ .
5. Assemble these lists `C` by concatenation into a new list of length `n2`.
6. Compute from the new list a string `ct` of corresponding letters.

Once it is known that the key is, say,  $n$  characters long, frequency analysis can be applied to every  $n$ -th letter of the ciphertext to determine the plaintext. This method is called *Kasiski examination* (although it was first discovered by Babbage). If the key is as long as the message and is comprised of randomly selected characters – a one-time pad – the message is theoretically unbreakable.

The cipher Vigenere actually discovered is an “auto-key” cipher described as follows.

ALGORITHM:

INPUT:

key: a string of letters (the secret key)

msg: string of letters (the plaintext message)

OUTPUT:

ct: string of upper-case letters (the ciphertext message)

STEPS:

0. Number the letters of the alphabet from 0, ...,  $N$
1. Compute from the string `msg` a list `L2` of corresponding integers. Let `n2 = len(L2)`.
2. Let `n1` be the length of the key. Append to the string `key` the first `n2 - n1` characters of the plaintext message. Compute from this string (also of length `n2`) a list `L1` of integers corresponding to the letter numbers in the first step.
3. Compute a new list `C` given by  $C[i] = L1[i] + L2[i] \pmod{N}$ .
4. Compute from the new list a string `ct` of letters corresponding to the new integers.

To decipher the auto-key ciphertext, the key is used to decipher the first `n1` characters and then those characters become the key to decipher the next `n1` characters, etc...:

```
>>> m = AZ('go navy, beat army! yes you can'); m
'GONAVYBEATARMYYESYOU CAN'
>>> key = AZ('gold bug'); n1 = len(key); n2 = len(m)
>>> auto_key = key + m[:n2 - n1]; auto_key
'GOLDBUGGONAVYBEATARMYYE'
>>> ct = encipher_vigenere(m, auto_key); ct
```

(continues on next page)

(continued from previous page)

```
'MCYDWSHKOGAMKZCELYFGAYR'
>>> n1 = len(key)
>>> pt = []
>>> while ct:
... part, ct = ct[:n1], ct[n1:]
... pt.append(decipher_vigenere(part, key))
... key = pt[-1]
...
>>> ''.join(pt) == m
True
```

## References

[R142], [R143], [R144]

`sympy.crypto.crypto.decipher_vigenere(msg, key, symbols=None)`  
Decode using the Vigenere cipher.

## Examples

```
>>> from sympy.crypto.crypto import decipher_vigenere
>>> key = "encrypt"
>>> ct = "QRGK kt HRZQE BPR"
>>> decipher_vigenere(ct, key)
'MEETMEONMONDAY'
```

`sympy.crypto.crypto.encipher_hill(msg, key, symbols=None, pad='Q')`  
Return the Hill cipher encryption of msg.

### Parameters

#### **msg**

Plaintext message of  $n$  upper-case letters.

#### **key**

A  $k \times k$  invertible matrix  $K$ , all of whose entries are in  $Z_{26}$  (or whatever number of symbols are being used).

#### **pad**

Character (default "Q") to use to make length of text be a multiple of  $k$ .

### Returns

ct

Ciphertext of upper-case letters.

## Explanation

The Hill cipher [R145], invented by Lester S. Hill in the 1920's [R146], was the first polygraphic cipher in which it was practical (though barely) to operate on more than three symbols at once. The following discussion assumes an elementary knowledge of matrices.

First, each letter is first encoded as a number starting with 0. Suppose your message *msg* consists of  $n$  capital letters, with no spaces. This may be regarded an  $n$ -tuple  $M$  of elements of  $Z_{26}$  (if the letters are those of the English alphabet). A key in the Hill cipher is a  $k \times k$  matrix  $K$ , all of whose entries are in  $Z_{26}$ , such that the matrix  $K$  is invertible (i.e., the linear transformation  $K : Z_N^k \rightarrow Z_N^k$  is one-to-one).

## Notes

ALGORITHM:

### STEPS:

0. Number the letters of the alphabet from 0, ..., N
1. Compute from the string *msg* a list *L* of corresponding integers. Let  $n = \text{len}(L)$ .
2. Break the list *L* up into  $t = \text{ceiling}(n/k)$  sublists  $L_1, \dots, L_t$  of size  $k$  (with the last list "padded" to ensure its size is  $k$ ).
3. Compute new list  $C_1, \dots, C_t$  given by  $C[i] = K * L_i$  (arithmetic is done mod  $N$ ), for each  $i$ .
4. Concatenate these into a list  $C = C_1 + \dots + C_t$ .
5. Compute from *C* a string *ct* of corresponding letters. This has length  $k*t$ .

[\*decipher\\_hill\*](#) (page 2773)

## References

[R145], [R146]

`sympy.crypto.crypto.decipher_hill(msg, key, symbols=None)`

Deciphering is the same as enciphering but using the inverse of the key matrix.

## Examples

```
>>> from sympy.crypto.crypto import encipher_hill, decipher_hill
>>> from sympy import Matrix
```

```
>>> key = Matrix([[1, 2], [3, 5]])
>>> encipher_hill("meet me on monday", key)
'UEQDUEODOCTCWQ'
```

(continues on next page)

(continued from previous page)

```
>>> decipher_hill(_, key)
'MEETMEONMONDAY'
```

When the length of the plaintext (stripped of invalid characters) is not a multiple of the key dimension, extra characters will appear at the end of the enciphered and deciphered text. In order to decipher the text, those characters must be included in the text to be deciphered. In the following, the key has a dimension of 4 but the text is 2 short of being a multiple of 4 so two characters will be added.

```
>>> key = Matrix([[1, 1, 1, 2], [0, 1, 1, 0],
... [2, 2, 3, 4], [1, 1, 0, 1]])
>>> msg = "ST"
>>> encipher_hill(msg, key)
'HJEB'
>>> decipher_hill(_, key)
'STQQ'
>>> encipher_hill(msg, key, pad="Z")
'ISPK'
>>> decipher_hill(_, key)
'STZZ'
```

If the last two characters of the ciphertext were ignored in either case, the wrong plaintext would be recovered:

```
>>> decipher_hill("HD", key)
'ORMV'
>>> decipher_hill("IS", key)
'UIKY'
```

**See also:**

[\*encipher\\_hill\*](#) (page 2772)

`sympy.crypto.crypto.encipher_bifid(msg, key, symbols=None)`

Performs the Bifid cipher encryption on plaintext `msg`, and returns the ciphertext.

This is the version of the Bifid cipher that uses an  $n \times n$  Polybius square.

**Parameters****msg**

Plaintext string.

**key**

Short string for key.

Duplicate characters are ignored and then it is padded with the characters in `symbols` that were not in the short key.

**symbols**

$n \times n$  characters defining the alphabet.

(default is `string.printable`)

**Returns**

ciphertext

Ciphertext using Bifid5 cipher without spaces.

**See also:**

[`decipher\_bifid`](#) (page 2775), [`encipher\_bifid5`](#) (page 2776), [`encipher\_bifid6`](#) (page 2778)

## References

[R147]

`sympy.crypto.crypto.decipher_bifid(msg, key, symbols=None)`

Performs the Bifid cipher decryption on ciphertext `msg`, and returns the plaintext.

This is the version of the Bifid cipher that uses the  $n \times n$  Polybius square.

### Parameters

#### **msg**

Ciphertext string.

#### **key**

Short string for key.

Duplicate characters are ignored and then it is padded with the characters in `symbols` that were not in the short key.

#### **symbols**

$n \times n$  characters defining the alphabet.

(default=`string.printable`, a  $10 \times 10$  matrix)

### Returns

deciphered

Deciphered text.

## Examples

```
>>> from sympy.crypto.crypto import (
... encipher_bifid, decipher_bifid, AZ)
```

Do an encryption using the bifid5 alphabet:

```
>>> alp = AZ().replace('J', '')
>>> ct = AZ("meet me on monday!")
>>> key = AZ("gold bug")
>>> encipher_bifid(ct, key, alp)
'IEILHHFSTSFQYE'
```

When entering the text or ciphertext, spaces are ignored so it can be formatted as desired. Re-entering the ciphertext from the preceding, putting 4 characters per line and padding with an extra J, does not cause problems for the deciphering:

```
>>> decipher_bifid(''
... IEILH
... HFSTS
... FQYEJ'', key, alp)
'MEETMEONMONDAY'
```

When no alphabet is given, all 100 printable characters will be used:

```
>>> key = ''
>>> encipher_bifid('hello world!', key)
'bmtwmg-bIo*w'
>>> decipher_bifid(_, key)
'hello world!'
```

If the key is changed, a different encryption is obtained:

```
>>> key = 'gold bug'
>>> encipher_bifid('hello world!', 'gold_bug')
'hg2sfuei7t}w'
```

And if the key used to decrypt the message is not exact, the original text will not be perfectly obtained:

```
>>> decipher_bifid(_, 'gold pug')
'helldo~wor6d!'
```

`sympy.crypto.crypto.bifid5_square(key=None)`

5x5 Polybius square.

Produce the Polybius square for the  $5 \times 5$  Bifid cipher.

### Examples

```
>>> from sympy.crypto.crypto import bifid5_square
>>> bifid5_square("gold bug")
Matrix([
[G, O, L, D, B],
[U, A, C, E, F],
[H, I, K, M, N],
[P, Q, R, S, T],
[V, W, X, Y, Z]])
```

`sympy.crypto.crypto.encipher_bifid5(msg, key)`

Performs the Bifid cipher encryption on plaintext `msg`, and returns the ciphertext.

#### Parameters

**msg** : str

Plaintext string.

Converted to upper case and filtered of anything but all letters except J.

**key**

Short string for key; non-alphabetic letters, J and duplicated characters are ignored and then, if the length is less than 25 characters, it is padded with other letters of the alphabet (in alphabetical order).

### Returns

ct

Ciphertext (all caps, no spaces).

### Explanation

This is the version of the Bifid cipher that uses the  $5 \times 5$  Polybius square. The letter "J" is ignored so it must be replaced with something else (traditionally an "I") before encryption.

ALGORITHM: (5x5 case)

#### STEPS:

0. Create the  $5 \times 5$  Polybius square  $S$  associated to key as follows:
  - a) moving from left-to-right, top-to-bottom, place the letters of the key into a  $5 \times 5$  matrix,
  - b) if the key has less than 25 letters, add the letters of the alphabet not in the key until the  $5 \times 5$  square is filled.
1. Create a list  $P$  of pairs of numbers which are the coordinates in the Polybius square of the letters in  $msg$ .
2. Let  $L1$  be the list of all first coordinates of  $P$  (length of  $L1 = n$ ), let  $L2$  be the list of all second coordinates of  $P$  (so the length of  $L2$  is also  $n$ ).
3. Let  $L$  be the concatenation of  $L1$  and  $L2$  (length  $L = 2*n$ ), except that consecutive numbers are paired ( $L[2*i]$ ,  $L[2*i + 1]$ ). You can regard  $L$  as a list of pairs of length  $n$ .
4. Let  $C$  be the list of all letters which are of the form  $S[i, j]$ , for all  $(i, j)$  in  $L$ . As a string, this is the ciphertext of  $msg$ .

### Examples

```
>>> from sympy.crypto.crypto import (
... encipher_bifid5, decipher_bifid5)
```

"J" will be omitted unless it is replaced with something else:

```
>>> round_trip = lambda m, k: \
... decipher_bifid5(encipher_bifid5(m, k), k)
>>> key = 'a'
>>> msg = "JOSIE"
>>> round_trip(msg, key)
'OSIE'
>>> round_trip(msg.replace("J", "I"), key)
'IOSIE'
>>> j = "QIQ"
```

(continues on next page)

(continued from previous page)

```
>>> round_trip(msg.replace("J", j), key).replace(j, "J")
'JOSIE'
```

## Notes

The Bifid cipher was invented around 1901 by Felix Delastelle. It is a *fractional substitution* cipher, where letters are replaced by pairs of symbols from a smaller alphabet. The cipher uses a  $5 \times 5$  square filled with some ordering of the alphabet, except that “J” is replaced with “I” (this is a so-called Polybius square; there is a  $6 \times 6$  analog if you add back in “J” and also append onto the usual 26 letter alphabet, the digits 0, 1, ..., 9). According to Helen Gaines’ book *Cryptanalysis*, this type of cipher was used in the field by the German Army during World War I.

### See also:

[\*decipher\\_bifid5\*](#) (page 2778), [\*encipher\\_bifid\*](#) (page 2774)

`sympy.crypto.crypto.decipher_bifid5(msg, key)`

Return the Bifid cipher decryption of msg.

### Parameters

#### **msg**

Ciphertext string.

#### **key**

Short string for key; duplicated characters are ignored and if the length is less than 25 characters, it will be padded with other letters from the alphabet omitting “J”. Non-alphabetic characters are ignored.

### Returns

plaintext

Plaintext from Bifid5 cipher (all caps, no spaces).

## Explanation

This is the version of the Bifid cipher that uses the  $5 \times 5$  Polybius square; the letter “J” is ignored unless a key of length 25 is used.

## Examples

```
>>> from sympy.crypto.crypto import encipher_bifid5, decipher_bifid5
>>> key = "gold bug"
>>> encipher_bifid5('meet me on friday', key)
'IEILEHFSFSXEE'
>>> encipher_bifid5('meet me on monday', key)
'IEILHHFSFSFYE'
>>> decipher_bifid5(_, key)
'MEETMEONMONDAY'
```

`sympy.crypto.crypto.encipher_bifid6(msg, key)`

Performs the Bifid cipher encryption on plaintext `msg`, and returns the ciphertext.

This is the version of the Bifid cipher that uses the  $6 \times 6$  Polybius square.

#### Parameters

##### **msg**

Plaintext string (digits okay).

##### **key**

Short string for key (digits okay).

If key is less than 36 characters long, the square will be filled with letters A through Z and digits 0 through 9.

#### Returns

ciphertext

Ciphertext from Bifid cipher (all caps, no spaces).

#### See also:

[\*decipher\\_bifid6\*](#) (page 2779), [\*encipher\\_bifid\*](#) (page 2774)

`sympy.crypto.crypto.decipher_bifid6(msg, key)`

Performs the Bifid cipher decryption on ciphertext `msg`, and returns the plaintext.

This is the version of the Bifid cipher that uses the  $6 \times 6$  Polybius square.

#### Parameters

##### **msg**

Ciphertext string (digits okay); converted to upper case

##### **key**

Short string for key (digits okay).

If key is less than 36 characters long, the square will be filled with letters A through Z and digits 0 through 9. All letters are converted to uppercase.

#### Returns

plaintext

Plaintext from Bifid cipher (all caps, no spaces).

#### Examples

```
>>> from sympy.crypto.crypto import encipher_bifid6, decipher_bifid6
>>> key = "gold bug"
>>> encipher_bifid6('meet me on monday at 8am', key)
'KFKLJJHF5MMMKTFRGPL'
>>> decipher_bifid6(_, key)
'MEETMEONMONDAYAT8AM'
```

`sympy.crypto.crypto.bifid6_square(key=None)`

6x6 Polybius square.

Produces the Polybius square for the  $6 \times 6$  Bifid cipher. Assumes alphabet of symbols is "A", ..., "Z", "0", ..., "9".

### Examples

```
>>> from sympy.crypto.crypto import bifid6_square
>>> key = "gold bug"
>>> bifid6_square(key)
Matrix([
 [G, O, L, D, B, U],
 [A, C, E, F, H, I],
 [J, K, M, N, P, Q],
 [R, S, T, V, W, X],
 [Y, Z, 0, 1, 2, 3],
 [4, 5, 6, 7, 8, 9]])
```

`sympy.crypto.crypto.rsa_public_key(*args, **kwargs)`

Return the RSA *public* key pair,  $(n, e)$

#### Parameters

**args** : naturals

If specified as  $p, q, e$  where  $p$  and  $q$  are distinct primes and  $e$  is a desired public exponent of the RSA,  $n = pq$  and  $e$  will be verified against the totient  $\phi(n)$  (Euler totient) or  $\lambda(n)$  (Carmichael totient) to be  $\gcd(e, \phi(n)) = 1$  or  $\gcd(e, \lambda(n)) = 1$ .

If specified as  $p_1, p_2, \dots, p_n, e$  where  $p_1, p_2, \dots, p_n$  are specified as primes, and  $e$  is specified as a desired public exponent of the RSA, it will be able to form a multi-prime RSA, which is a more generalized form of the popular 2-prime RSA.

It can also be possible to form a single-prime RSA by specifying the argument as  $p, e$ , which can be considered a trivial case of a multi-prime RSA.

Furthermore, it can be possible to form a multi-power RSA by specifying two or more pairs of the primes to be same. However, unlike the two-distinct prime RSA or multi-prime RSA, not every numbers in the complete residue system  $(\mathbb{Z}_n)$  will be decryptable since the mapping  $\mathbb{Z}_n \rightarrow \mathbb{Z}_n$  will not be bijective. (Only except for the trivial case when  $e = 1$  or more generally,

$$e \in \{1 + k\lambda(n) \mid k \in \mathbb{Z} \wedge k \geq 0\}$$

when RSA reduces to the identity.) However, the RSA can still be decryptable for the numbers in the reduced residue system  $(\mathbb{Z}_n^\times)$ , since the mapping  $\mathbb{Z}_n^\times \rightarrow \mathbb{Z}_n^\times$  can still be bijective.

If you pass a non-prime integer to the arguments  $p_1, p_2, \dots, p_n$ , the particular number will be prime-factored and it will become either a multi-prime RSA or a multi-power RSA in its canonical form, depending on whether the product equals its radical or not.  $p_1 p_2 \dots p_n = \text{rad}(p_1 p_2 \dots p_n)$

**totient** : bool, optional

If 'Euler', it uses Euler's totient  $\phi(n)$  which is `sympy.ntheory.factor_.totient()` (page 1501) in SymPy.

If 'Carmichael', it uses Carmichael's totient  $\lambda(n)$  which is `sympy.ntheory.factor_.reduced_totient()` (page 1501) in SymPy.

Unlike private key generation, this is a trivial keyword for public key generation because  $\gcd(e, \phi(n)) = 1 \iff \gcd(e, \lambda(n)) = 1$ .

**index** : nonnegative integer, optional

Returns an arbitrary solution of a RSA public key at the index specified at 0, 1, 2, .... This parameter needs to be specified along with `totient='Carmichael'`.

Similarly to the non-uniqueness of a RSA private key as described in the `index` parameter documentation in `rsa_private_key()` (page 2782), RSA public key is also not unique and there is an infinite number of RSA public exponents which can behave in the same manner.

From any given RSA public exponent  $e$ , there can be another RSA public exponent  $e + k\lambda(n)$  where  $k$  is an integer,  $\lambda$  is a Carmichael's totient function.

However, considering only the positive cases, there can be a principal solution of a RSA public exponent  $e_0$  in  $0 < e_0 < \lambda(n)$ , and all the other solutions can be canonicalized in a form of  $e_0 + k\lambda(n)$ .

`index` specifies the  $k$  notation to yield any possible value an RSA public key can have.

An example of computing any arbitrary RSA public key:

```
>>> from sympy.crypto.crypto import rsa_public_key
>>> rsa_public_key(61, 53, 17, totient='Carmichael',
 ↪ index=0)
(3233, 17)
>>> rsa_public_key(61, 53, 17, totient='Carmichael',
 ↪ index=1)
(3233, 797)
>>> rsa_public_key(61, 53, 17, totient='Carmichael',
 ↪ index=2)
(3233, 1577)
```

**multipower** : bool, optional

Any pair of non-distinct primes found in the RSA specification will restrict the domain of the cryptosystem, as noted in the explanation of the parameter `args`.

SymPy RSA key generator may give a warning before dispatching it as a multi-power RSA, however, you can disable the warning if you pass `True` to this keyword.

## Returns

(**n**, **e**) : int, int

$n$  is a product of any arbitrary number of primes given as the argument.

$e$  is relatively prime (coprime) to the Euler totient  $\phi(n)$ .

False

Returned if less than two arguments are given, or  $e$  is not relatively prime to the modulus.

## Examples

```
>>> from sympy.crypto.crypto import rsa_public_key
```

A public key of a two-prime RSA:

```
>>> p, q, e = 3, 5, 7
>>> rsa_public_key(p, q, e)
(15, 7)
>>> rsa_public_key(p, q, 30)
False
```

A public key of a multiprime RSA:

```
>>> primes = [2, 3, 5, 7, 11, 13]
>>> e = 7
>>> args = primes + [e]
>>> rsa_public_key(*args)
(30030, 7)
```

## Notes

Although the RSA can be generalized over any modulus  $n$ , using two large primes had become the most popular specification because a product of two large primes is usually the hardest to factor relatively to the digits of  $n$  can have.

However, it may need further understanding of the time complexities of each prime-factoring algorithms to verify the claim.

### See also:

[rsa\\_private\\_key](#) (page 2782), [encipher\\_rsa](#) (page 2784), [decipher\\_rsa](#) (page 2785)

## References

[R148], [R149], [R150], [R151]

`sympy.crypto.crypto.rsa_private_key(*args, **kwargs)`

Return the RSA *private* key pair,  $(n, d)$

### Parameters

**args** : naturals

The keyword is identical to the args in [rsa\\_public\\_key\(\)](#) (page 2780).

**totient** : bool, optional

If 'Euler', it uses Euler's totient convention  $\phi(n)$  which is `sympy.ntheory.factor_.totient()` (page 1501) in SymPy.

If 'Carmichael', it uses Carmichael's totient convention  $\lambda(n)$  which is `sympy.ntheory.factor_.reduced_totient()` (page 1501) in SymPy.

There can be some output differences for private key generation as examples below.

Example using Euler's totient:

```
>>> from sympy.crypto.crypto import rsa_private_key
>>> rsa_private_key(61, 53, 17, totient='Euler')
(3233, 2753)
```

Example using Carmichael's totient:

```
>>> from sympy.crypto.crypto import rsa_private_key
>>> rsa_private_key(61, 53, 17, totient='Carmichael')
(3233, 413)
```

**index** : nonnegative integer, optional

Returns an arbitrary solution of a RSA private key at the index specified at 0,1,2,... This parameter needs to be specified along with `totient='Carmichael'`.

RSA private exponent is a non-unique solution of  $ed \bmod \lambda(n) = 1$  and it is possible in any form of  $d + k\lambda(n)$ , where  $d$  is an another already-computed private exponent, and  $\lambda$  is a Carmichael's totient function, and  $k$  is any integer.

However, considering only the positive cases, there can be a principal solution of a RSA private exponent  $d_0$  in  $0 < d_0 < \lambda(n)$ , and all the other solutions can be canonicalized in a form of  $d_0 + k\lambda(n)$ .

`index` specifies the  $k$  notation to yield any possible value an RSA private key can have.

An example of computing any arbitrary RSA private key:

```
>>> from sympy.crypto.crypto import rsa_private_key
>>> rsa_private_key(61, 53, 17, totient='Carmichael',
↪ index=0)
(3233, 413)
>>> rsa_private_key(61, 53, 17, totient='Carmichael',
↪ index=1)
(3233, 1193)
>>> rsa_private_key(61, 53, 17, totient='Carmichael',
↪ index=2)
(3233, 1973)
```

**multipower** : bool, optional

The keyword is identical to the `multipower` in `rsa_public_key()` (page 2780).

**Returns****(n, d)** : int, int

$n$  is a product of any arbitrary number of primes given as the argument.

$d$  is the inverse of  $e \pmod{\phi(n)}$  where  $e$  is the exponent given, and  $\phi$  is a Euler totient.

False

Returned if less than two arguments are given, or  $e$  is not relatively prime to the totient of the modulus.

**Examples**

```
>>> from sympy.crypto.crypto import rsa_private_key
```

A private key of a two-prime RSA:

```
>>> p, q, e = 3, 5, 7
>>> rsa_private_key(p, q, e)
(15, 7)
>>> rsa_private_key(p, q, 30)
False
```

A private key of a multiprime RSA:

```
>>> primes = [2, 3, 5, 7, 11, 13]
>>> e = 7
>>> args = primes + [e]
>>> rsa_private_key(*args)
(30030, 823)
```

**References**

[R152], [R153], [R154], [R155]

`sympy.crypto.crypto.encipher_rsa(i, key, factors=None)`

Encrypt the plaintext with RSA.

**Parameters****i** : integer

The plaintext to be encrypted for.

**key** : (n, e) where n, e are integers

$n$  is the modulus of the key and  $e$  is the exponent of the key. The encryption is computed by  $i^e \pmod n$ .

The key can either be a public key or a private key, however, the message encrypted by a public key can only be decrypted by a private key, and vice versa, as RSA is an asymmetric cryptography system.

**factors** : list of coprime integers

This is identical to the keyword `factors` in `decipher_rsa()` (page 2785).

## Notes

Some specifications may make the RSA not cryptographically meaningful.

For example, 0, 1 will remain always same after taking any number of exponentiation, thus, should be avoided.

Furthermore, if  $i^e < n$ ,  $i$  may easily be figured out by taking  $e$  th root.

And also, specifying the exponent as 1 or in more generalized form as  $1 + k\lambda(n)$  where  $k$  is an nonnegative integer,  $\lambda$  is a carmichael totient, the RSA becomes an identity mapping.

## Examples

```
>>> from sympy.crypto.crypto import encipher_rsa
>>> from sympy.crypto.crypto import rsa_public_key, rsa_private_key
```

Public Key Encryption:

```
>>> p, q, e = 3, 5, 7
>>> puk = rsa_public_key(p, q, e)
>>> msg = 12
>>> encipher_rsa(msg, puk)
3
```

Private Key Encryption:

```
>>> p, q, e = 3, 5, 7
>>> prk = rsa_private_key(p, q, e)
>>> msg = 12
>>> encipher_rsa(msg, prk)
3
```

Encryption using chinese remainder theorem:

```
>>> encipher_rsa(msg, prk, factors=[p, q])
3
```

`sympy.crypto.crypto.decipher_rsa(i, key, factors=None)`

Decrypt the ciphertext with RSA.

### Parameters

**i** : integer

The ciphertext to be decrypted for.

**key** : (*n*, *d*) where *n*, *d* are integers

*n* is the modulus of the key and *d* is the exponent of the key. The decryption is computed by  $i^d \bmod n$ .

The key can either be a public key or a private key, however, the message encrypted by a public key can only be decrypted by a private key, and vice versa, as RSA is an asymmetric cryptography system.

**factors** : list of coprime integers

As the modulus  $n$  created from RSA key generation is composed of arbitrary prime factors  $n = p_1^{k_1} p_2^{k_2} \dots p_n^{k_n}$  where  $p_1, p_2, \dots, p_n$  are distinct primes and  $k_1, k_2, \dots, k_n$  are positive integers, chinese remainder theorem can be used to compute  $i^d \bmod n$  from the fragmented modulo operations like

$$i^d \bmod p_1^{k_1}, i^d \bmod p_2^{k_2}, \dots, i^d \bmod p_n^{k_n}$$

or like

$$i^d \bmod p_1^{k_1} p_2^{k_2}, i^d \bmod p_3^{k_3}, \dots, i^d \bmod p_n^{k_n}$$

as long as every moduli does not share any common divisor each other.

The raw primes used in generating the RSA key pair can be a good option.

Note that the speed advantage of using this is only viable for very large cases (Like 2048-bit RSA keys) since the overhead of using pure Python implementation of [sympy.nttheory.modular.crt\(\)](#) (page 1509) may overcompensate the theoretical speed advantage.

## Notes

See the Notes section in the documentation of [encipher\\_rsa\(\)](#) (page 2784)

## Examples

```
>>> from sympy.crypto.crypto import decipher_rsa, encipher_rsa
>>> from sympy.crypto.crypto import rsa_public_key, rsa_private_key
```

Public Key Encryption and Decryption:

```
>>> p, q, e = 3, 5, 7
>>> prk = rsa_private_key(p, q, e)
>>> puk = rsa_public_key(p, q, e)
>>> msg = 12
>>> new_msg = encipher_rsa(msg, prk)
>>> new_msg
3
>>> decipher_rsa(new_msg, puk)
12
```

Private Key Encryption and Decryption:

```
>>> p, q, e = 3, 5, 7
>>> prk = rsa_private_key(p, q, e)
>>> puk = rsa_public_key(p, q, e)
>>> msg = 12
>>> new_msg = encipher_rsa(msg, puk)
>>> new_msg
3
>>> decipher_rsa(new_msg, prk)
12
```

Decryption using chinese remainder theorem:

```
>>> decipher_rsa(new_msg, prk, factors=[p, q])
12
```

**See also:**

[`encipher\_rsa`](#) (page 2784)

`sympy.crypto.crypto.kid_rsa_public_key(a, b, A, B)`

Kid RSA is a version of RSA useful to teach grade school children since it does not involve exponentiation.

### Explanation

Alice wants to talk to Bob. Bob generates keys as follows. Key generation:

- Select positive integers  $a, b, A, B$  at random.
- Compute  $M = ab - 1$ ,  $e = AM + a$ ,  $d = BM + b$ ,  $n = (ed - 1)/M$ .
- The *public key* is  $(n, e)$ . Bob sends these to Alice.
- The *private key* is  $(n, d)$ , which Bob keeps secret.

Encryption: If  $p$  is the plaintext message then the ciphertext is  $c = pe \pmod{n}$ .

Decryption: If  $c$  is the ciphertext message then the plaintext is  $p = cd \pmod{n}$ .

### Examples

```
>>> from sympy.crypto.crypto import kid_rsa_public_key
>>> a, b, A, B = 3, 4, 5, 6
>>> kid_rsa_public_key(a, b, A, B)
(369, 58)
```

`sympy.crypto.crypto.kid_rsa_private_key(a, b, A, B)`

Compute  $M = ab - 1$ ,  $e = AM + a$ ,  $d = BM + b$ ,  $n = (ed - 1)/M$ . The *private key* is  $d$ , which Bob keeps secret.

### Examples

```
>>> from sympy.crypto.crypto import kid_rsa_private_key
>>> a, b, A, B = 3, 4, 5, 6
>>> kid_rsa_private_key(a, b, A, B)
(369, 70)
```

`sympy.crypto.crypto.encipher_kid_rsa(msg, key)`  
Here msg is the plaintext and key is the public key.

### Examples

```
>>> from sympy.crypto.crypto import (
... encipher_kid_rsa, kid_rsa_public_key)
>>> msg = 200
>>> a, b, A, B = 3, 4, 5, 6
>>> key = kid_rsa_public_key(a, b, A, B)
>>> encipher_kid_rsa(msg, key)
161
```

`sympy.crypto.crypto.decipher_kid_rsa(msg, key)`  
Here msg is the plaintext and key is the private key.

### Examples

```
>>> from sympy.crypto.crypto import (
... kid_rsa_public_key, kid_rsa_private_key,
... decipher_kid_rsa, encipher_kid_rsa)
>>> a, b, A, B = 3, 4, 5, 6
>>> d = kid_rsa_private_key(a, b, A, B)
>>> msg = 200
>>> pub = kid_rsa_public_key(a, b, A, B)
>>> pri = kid_rsa_private_key(a, b, A, B)
>>> ct = encipher_kid_rsa(msg, pub)
>>> decipher_kid_rsa(ct, pri)
200
```

`sympy.crypto.crypto.encode_morse(msg, sep='|', mapping=None)`  
Encodes a plaintext into popular Morse Code with letters separated by sep and words by a double sep.

## Examples

```
>>> from sympy.crypto.crypto import encode_morse
>>> msg = 'ATTACK RIGHT FLANK'
>>> encode_morse(msg)
'.-|-|-|. -|. -..|. -..|.|..|..|...|-||...|. -..|. -|. -|. -..'
```

## References

[R156]

`sympy.crypto.crypto.decode_morse(msg, sep='|', mapping=None)`

Decodes a Morse Code with letters separated by `sep` (default is '|') and words by `word_sep` (default is '||') into plaintext.

## Examples

```
>>> from sympy.crypto.crypto import decode_morse
>>> mc = '-.-|---|...|.|||.|-|...|-'
>>> decode_morse(mc)
'MOVE EAST'
```

## References

[R157]

`sympy.crypto.crypto.lfsr_sequence(key, fill, n)`

This function creates an LFSR sequence.

### Parameters

**key** : list

A list of finite field elements,  $[c_0, c_1, \dots, c_k]$ .

**fill** : list

The list of the initial terms of the LFSR sequence,  $[x_0, x_1, \dots, x_k]$ .

**n**

Number of terms of the sequence that the function returns.

### Returns

L

The LFSR sequence defined by  $x_{n+1} = c_k x_n + \dots + c_0 x_{n-k}$ , for  $n \leq k$ .

## Notes

S. Golomb [G157] gives a list of three statistical properties a sequence of numbers  $a = \{a_n\}_{n=1}^{\infty}$ ,  $a_n \in \{0, 1\}$ , should display to be considered “random”. Define the autocorrelation of  $a$  to be

$$C(k) = C(k, a) = \lim_{N \rightarrow \infty} \frac{1}{N} \sum_{n=1}^N (-1)^{a_n + a_{n+k}}.$$

In the case where  $a$  is periodic with period  $P$  then this reduces to

$$C(k) = \frac{1}{P} \sum_{n=1}^P (-1)^{a_n + a_{n+k}}.$$

Assume  $a$  is periodic with period  $P$ .

- balance:

$$\left| \sum_{n=1}^P (-1)^{a_n} \right| \leq 1.$$

- low autocorrelation:

$$C(k) = \begin{cases} 1, & k = 0, \\ \epsilon, & k \neq 0. \end{cases}$$

(For sequences satisfying these first two properties, it is known that  $\epsilon = -1/P$  must hold.)

- proportional runs property: In each period, half the runs have length 1, one-fourth have length 2, etc. Moreover, there are as many runs of 1’s as there are of 0’s.

## Examples

```
>>> from sympy.crypto.crypto import lfsr_sequence
>>> from sympy.polys.domains import FF
>>> F = FF(2)
>>> fill = [F(1), F(1), F(0), F(1)]
>>> key = [F(1), F(0), F(0), F(1)]
>>> lfsr_sequence(key, fill, 10)
[1 mod 2, 1 mod 2, 0 mod 2, 1 mod 2, 0 mod 2,
1 mod 2, 1 mod 2, 0 mod 2, 0 mod 2, 1 mod 2]
```

## References

[G157]

`sympy.crypto.crypto.lfsr_autocorrelation(L, P, k)`

This function computes the LFSR autocorrelation function.

**Parameters****L**

A periodic sequence of elements of  $GF(2)$ . L must have length larger than P.

**P**

The period of L.

**k** : int

An integer  $k$  ( $0 < k < P$ ).

**Returns**

autocorrelation

The k-th value of the autocorrelation of the LFSR L.

**Examples**

```
>>> from sympy.crypto.crypto import (
... lfsr_sequence, lfsr_autocorrelation)
>>> from sympy.polys.domains import FF
>>> F = FF(2)
>>> fill = [F(1), F(1), F(0), F(1)]
>>> key = [F(1), F(0), F(0), F(1)]
>>> s = lfsr_sequence(key, fill, 20)
>>> lfsr_autocorrelation(s, 15, 7)
-1/15
>>> lfsr_autocorrelation(s, 15, 0)
1
```

`sympy.crypto.crypto.lfsr_connection_polynomial(s)`

This function computes the LFSR connection polynomial.

**Parameters****s**

A sequence of elements of even length, with entries in a finite field.

**Returns**

$C(x)$

The connection polynomial of a minimal LFSR yielding s.

This implements the algorithm in section 3 of J. L. Massey's article [\[M158\]](#).

## Examples

```
>>> from sympy.crypto.crypto import (
... lfsr_sequence, lfsr_connection_polynomial)
>>> from sympy.polys.domains import FF
>>> F = FF(2)
>>> fill = [F(1), F(1), F(0), F(1)]
>>> key = [F(1), F(0), F(0), F(1)]
>>> s = lfsr_sequence(key, fill, 20)
>>> lfsr_connection_polynomial(s)
x**4 + x + 1
>>> fill = [F(1), F(0), F(0), F(1)]
>>> key = [F(1), F(1), F(0), F(1)]
>>> s = lfsr_sequence(key, fill, 20)
>>> lfsr_connection_polynomial(s)
x**3 + 1
>>> fill = [F(1), F(0), F(1)]
>>> key = [F(1), F(1), F(0)]
>>> s = lfsr_sequence(key, fill, 20)
>>> lfsr_connection_polynomial(s)
x**3 + x**2 + 1
>>> fill = [F(1), F(0), F(1)]
>>> key = [F(1), F(0), F(1)]
>>> s = lfsr_sequence(key, fill, 20)
>>> lfsr_connection_polynomial(s)
x**3 + x + 1
```

## References

[M158]

`sympy.crypto.crypto.elgamal_public_key(key)`

Return three number tuple as public key.

### Parameters

**key** : (p, r, e)

Tuple generated by `elgamal_private_key`.

### Returns

**tuple** : (p, r, e)

$e = r ** d \bmod p$

$d$  is a random number in private key.

## Examples

```
>>> from sympy.crypto.crypto import elgamal_public_key
>>> elgamal_public_key((1031, 14, 636))
(1031, 14, 212)
```

`sympy.crypto.crypto.elgamal_private_key(digit=10, seed=None)`

Return three number tuple as private key.

### Parameters

**digit** : int

Minimum number of binary digits for key.

### Returns

**tuple** : (p, r, d)

p = prime number.

r = primitive root.

d = random number.

## Explanation

Elgamal encryption is based on the mathematical problem called the Discrete Logarithm Problem (DLP). For example,

$$a^b \equiv c \pmod{p}$$

In general, if a and b are known, ct is easily calculated. If b is unknown, it is hard to use a and ct to get b.

## Notes

For testing purposes, the seed parameter may be set to control the output of this routine. See `sympy.core.random._randrange`.

## Examples

```
>>> from sympy.crypto.crypto import elgamal_private_key
>>> from sympy.ntheory import is_primitive_root, isprime
>>> a, b, _ = elgamal_private_key()
>>> isprime(a)
True
>>> is_primitive_root(b, a)
True
```

`sympy.crypto.crypto.encipher_elgamal(i, key, seed=None)`

Encrypt message with public key.

### Parameters

**msg**

int of encoded message.

**key**

Public key.

**Returns**

**tuple** : (c1, c2)

Encipher into two number.

**Explanation**

i is a plaintext message expressed as an integer. key is public key (p, r, e). In order to encrypt a message, a random number a in `range(2, p)` is generated and the encrypted message is returned as  $c_1$  and  $c_2$  where:

$$c_1 \equiv r^a \pmod{p}$$

$$c_2 \equiv me^a \pmod{p}$$

**Notes**

For testing purposes, the seed parameter may be set to control the output of this routine. See `sympy.core.random._randrange`.

**Examples**

```
>>> from sympy.crypto.crypto import encipher_elgamal, elgamal_private_
 ↪key, elgamal_public_key
>>> pri = elgamal_private_key(5, seed=[3]); pri
(37, 2, 3)
>>> pub = elgamal_public_key(pri); pub
(37, 2, 8)
>>> msg = 36
>>> encipher_elgamal(msg, pub, seed=[3])
(8, 6)
```

`sympy.crypto.crypto.decipher_elgamal(msg, key)`

Decrypt message with private key.

$$msg = (c_1, c_2)$$

$$key = (p, r, d)$$

According to extended Eucliden theorem,  $uc_1^d + pn = 1$

$$u \equiv 1/c_1^d \pmod{p}$$

$$uc_2 \equiv \frac{1}{c_1^d} c_2 \equiv \frac{1}{r^{ad}} c_2 \pmod{p}$$

$$\frac{1}{r^{ad}} me^a \equiv \frac{1}{r^{ad}} mr^{da} \equiv m \pmod{p}$$

## Examples

```
>>> from sympy.crypto.crypto import decipher_elgamal
>>> from sympy.crypto.crypto import encipher_elgamal
>>> from sympy.crypto.crypto import elgamal_private_key
>>> from sympy.crypto.crypto import elgamal_public_key

>>> pri = elgamal_private_key(5, seed=[3])
>>> pub = elgamal_public_key(pri); pub
(37, 2, 8)
>>> msg = 17
>>> decipher_elgamal(encipher_elgamal(msg, pub), pri) == msg
True
```

`sympy.crypto.crypto.dh_public_key(key)`

Return three number tuple as public key.

This is the tuple that Alice sends to Bob.

### Parameters

**key** : (p, g, a)

A tuple generated by `dh_private_key`.

### Returns

**tuple** : int, int, int

A tuple of  $(p, g, g^a \bmod p)$  with  $p$ ,  $g$  and  $a$  given as parameters.s

## Examples

```
>>> from sympy.crypto.crypto import dh_private_key, dh_public_key
>>> p, g, a = dh_private_key();
>>> _p, _g, x = dh_public_key((p, g, a))
>>> p == _p and g == _g
True
>>> x == pow(g, a, p)
True
```

`sympy.crypto.crypto.dh_private_key(digit=10, seed=None)`

Return three integer tuple as private key.

### Parameters

**digit**

Minimum number of binary digits required in key.

### Returns

**tuple** : (p, g, a)

p = prime number.

g = primitive root of p.

a = random number from 2 through p - 1.

## Explanation

Diffie-Hellman key exchange is based on the mathematical problem called the Discrete Logarithm Problem (see ElGamal).

Diffie-Hellman key exchange is divided into the following steps:

- Alice and Bob agree on a base that consist of a prime  $p$  and a primitive root of  $p$  called  $g$
- Alice choses a number  $a$  and Bob choses a number  $b$  where  $a$  and  $b$  are random numbers in range  $[2, p)$ . These are their private keys.
- Alice then publicly sends Bob  $g^a \pmod{p}$  while Bob sends Alice  $g^b \pmod{p}$
- They both raise the received value to their secretly chosen number ( $a$  or  $b$ ) and now have both as their shared key  $g^{ab} \pmod{p}$

## Notes

For testing purposes, the seed parameter may be set to control the output of this routine. See `sympy.core.random._randrange`.

## Examples

```
>>> from sympy.crypto.crypto import dh_private_key
>>> from sympy.ntheory import isprime, is_primitive_root
>>> p, g, _ = dh_private_key()
>>> isprime(p)
True
>>> is_primitive_root(g, p)
True
>>> p, g, _ = dh_private_key(5)
>>> isprime(p)
True
>>> is_primitive_root(g, p)
True
```

`sympy.crypto.crypto.dh_shared_key(key, b)`

Return an integer that is the shared key.

This is what Bob and Alice can both calculate using the public keys they received from each other and their private keys.

### Parameters

**key** :  $(p, g, x)$

Tuple  $(p, g, x)$  generated by `dh_public_key`.

**b**

Random number in the range of 2 to  $p - 1$  (Chosen by second key exchange member (Bob)).

### Returns

int

A shared key.

## Examples

```
>>> from sympy.crypto.crypto import (
... dh_private_key, dh_public_key, dh_shared_key)
>>> prk = dh_private_key();
>>> p, g, x = dh_public_key(prk);
>>> sk = dh_shared_key((p, g, x), 1000)
>>> sk == pow(x, 1000, p)
True
```

`sympy.crypto.crypto.gm_public_key(p, q, a=None, seed=None)`

Compute public keys for p and q. Note that in Goldwasser-Micali Encryption, public keys are randomly selected.

### Parameters

**p, q, a** : int, int, int

Initialization variables.

### Returns

**tuple** : (a, N)

a is the input a if it is not None otherwise some random integer co-prime to p and q.

N is the product of p and q.

`sympy.crypto.crypto.gm_private_key(p, q, a=None)`

Check if p and q can be used as private keys for the Goldwasser-Micali encryption. The method works roughly as follows.

### Parameters

**p, q, a**

Initialization variables.

### Returns

**tuple** : (p, q)

The input value p and q.

### Raises

#### ValueError

If p and q are not distinct odd primes.

**Explanation**

1. Pick two large primes  $p$  and  $q$ .
2. Call their product  $N$ .
3. Given a message as an integer  $i$ , write  $i$  in its bit representation  $b_0, \dots, b_n$ .
4. For each  $k$ ,  
  
    **if**  $b_k = 0$ :  
        let  $a_k$  be a random square (quadratic residue) modulo  $pq$  such that  
        `jacobi_symbol(a, p*q) = 1`  
  
    **if**  $b_k = 1$ :  
        let  $a_k$  be a random non-square (non-quadratic residue) modulo  $pq$  such that  
        `jacobi_symbol(a, p*q) = -1`

returns  $[a_1, a_2, \dots]$

$b_k$  can be recovered by checking whether or not  $a_k$  is a residue. And from the  $b_k$ 's, the message can be reconstructed.

The idea is that, while `jacobi_symbol(a, p*q)` can be easily computed (and when it is equal to  $-1$  will tell you that  $a$  is not a square mod  $pq$ ), quadratic residuosity modulo a composite number is hard to compute without knowing its factorization.

Moreover, approximately half the numbers coprime to  $pq$  have `jacobi_symbol()` (page 1522) equal to 1. And among those, approximately half are residues and approximately half are not. This maximizes the entropy of the code.

`sympy.crypto.crypto.encipher_gm(i, key, seed=None)`

Encrypt integer 'i' using public\_key 'key' Note that gm uses random encryption.

**Parameters**

**i** : int

The message to encrypt.

**key** : (a, N)

The public key.

**Returns**

**list** : list of int

The randomized encrypted message.

`sympy.crypto.crypto.decipher_gm(message, key)`

Decrypt message 'message' using public\_key 'key'.

**Parameters**

**message** : list of int

The randomized encrypted message.

**key** : (p, q)

The private key.

**Returns**

int

The encrypted message.

`sympy.crypto.crypto.encipher_railfence(message, rails)`

Performs Railfence Encryption on plaintext and returns ciphertext

**Parameters**

**message** : string, the message to encrypt.

**rails** : int, the number of rails.

**Returns**

The Encrypted string message.

**Examples**

```
>>> from sympy.crypto.crypto import encipher_railfence
>>> message = "hello world"
>>> encipher_railfence(message,3)
'horel ollwd'
```

**References**

[R160]

`sympy.crypto.crypto.decipher_railfence(ciphertext, rails)`

Decrypt the message using the given rails

**Parameters**

**message** : string, the message to encrypt.

**rails** : int, the number of rails.

**Returns**

The Decrypted string message.

**Examples**

```
>>> from sympy.crypto.crypto import decipher_railfence
>>> decipher_railfence("horel ollwd",3)
'hello world'
```

## Differential Geometry

### Introduction

### Base Class Reference

`class sympy.diffgeom.Manifold(name, dim, **kwargs)`

A mathematical manifold.

**Parameters**

**name** : str

The name of the manifold.

**dim** : int

The dimension of the manifold.

### Explanation

A manifold is a topological space that locally resembles Euclidean space near each point [1]. This class does not provide any means to study the topological characteristics of the manifold that it represents, though.

### Examples

```
>>> from sympy.diffgeom import Manifold
>>> m = Manifold('M', 2)
>>> m
M
>>> m.dim
2
```

### References

[R161]

**class** sympy.diffgeom.**Patch**(*name*, *manifold*, *\*\*kwargs*)

A patch on a manifold.

#### Parameters

**name** : str

The name of the patch.

**manifold** : Manifold

The manifold on which the patch is defined.

### Explanation

Coordinate patch, or patch in short, is a simply-connected open set around a point in the manifold [1]. On a manifold one can have many patches that do not always include the whole manifold. On these patches coordinate charts can be defined that permit the parameterization of any point on the patch in terms of a tuple of real numbers (the coordinates).

This class does not provide any means to study the topological characteristics of the patch that it represents.

## Examples

```
>>> from sympy.diffgeom import Manifold, Patch
>>> m = Manifold('M', 2)
>>> p = Patch('P', m)
>>> p
P
>>> p.dim
2
```

## References

[R162]

```
class sympy.diffgeom.CoordSystem(name, patch, symbols=None, relations={},
 **kwargs)
```

A coordinate system defined on the patch.

### Parameters

**name** : str

The name of the coordinate system.

**patch** : Patch

The patch where the coordinate system is defined.

**symbols** : list of Symbols, optional

Defines the names and assumptions of coordinate symbols.

**relations** : dict, optional

Key is a tuple of two strings, who are the names of the systems where the coordinates transform from and transform to. Value is a tuple of the symbols before transformation and a tuple of the expressions after transformation.

## Explanation

Coordinate system is a system that uses one or more coordinates to uniquely determine the position of the points or other geometric elements on a manifold [1].

By passing Symbols to *symbols* parameter, user can define the name and assumptions of coordinate symbols of the coordinate system. If not passed, these symbols are generated automatically and are assumed to be real valued.

By passing *relations* parameter, user can define the tranform relations of coordinate systems. Inverse transformation and indirect transformation can be found automatically. If this parameter is not passed, coordinate transformation cannot be done.

## Examples

We define two-dimensional Cartesian coordinate system and polar coordinate system.

```
>>> from sympy import symbols, pi, sqrt, atan2, cos, sin
>>> from sympy.diffgeom import Manifold, Patch, CoordSystem
>>> m = Manifold('M', 2)
>>> p = Patch('P', m)
>>> x, y = symbols('x y', real=True)
>>> r, theta = symbols('r theta', nonnegative=True)
>>> relation_dict = {
... ('Car2D', 'Pol'): [(x, y), (sqrt(x**2 + y**2), atan2(y, x))],
... ('Pol', 'Car2D'): [(r, theta), (r*cos(theta), r*sin(theta))]
... }
>>> Car2D = CoordSystem('Car2D', p, (x, y), relation_dict)
>>> Pol = CoordSystem('Pol', p, (r, theta), relation_dict)
```

`symbols` property returns `CoordinateSymbol` instances. These symbols are not same with the symbols used to construct the coordinate system.

```
>>> Car2D
Car2D
>>> Car2D.dim
2
>>> Car2D.symbols
(x, y)
>>> _[0].func
<class 'sympy.diffgeom.diffgeom.CoordinateSymbol'>
```

`transformation()` method returns the transformation function from one coordinate system to another. `transform()` method returns the transformed coordinates.

```
>>> Car2D.transformation(Pol)
Lambda((x, y), Matrix([
[sqrt(x**2 + y**2)],
[atan2(y, x)]]))
>>> Car2D.transform(Pol)
Matrix([
[sqrt(x**2 + y**2)],
[atan2(y, x)]])
>>> Car2D.transform(Pol, [1, 2])
Matrix([
[sqrt(5)],
[atan(2)]])
```

`jacobian()` method returns the Jacobian matrix of coordinate transformation between two systems. `jacobian_determinant()` method returns the Jacobian determinant of coordinate transformation between two systems.

```
>>> Pol.jacobian(Car2D)
Matrix([
[cos(theta), -r*sin(theta)],
[sin(theta), r*cos(theta)]]
>>> Pol.jacobian(Car2D, [1, pi/2])
```

(continues on next page)

(continued from previous page)

```

Matrix([
[0, -1],
[1, 0]])
>>> Car2D.jacobian_determinant(Pol)
1/sqrt(x**2 + y**2)
>>> Car2D.jacobian_determinant(Pol, [1,0])
1

```

## References

[R163]

**base\_oneform**(*coord\_index*)

Return a basis 1-form field. The basis one-form field for this coordinate system. It is also an operator on vector fields.

**base\_oneforms**()

Returns a list of all base oneforms. For more details see the `base_oneform` method of this class.

**base\_scalar**(*coord\_index*)

Return `BaseScalarField` that takes a point and returns one of the coordinates.

**base\_scalars**()

Returns a list of all coordinate functions. For more details see the `base_scalar` method of this class.

**base\_vector**(*coord\_index*)

Return a basis vector field. The basis vector field for this coordinate system. It is also an operator on scalar fields.

**base\_vectors**()

Returns a list of all base vectors. For more details see the `base_vector` method of this class.

**coord\_function**(*coord\_index*)

Return `BaseScalarField` that takes a point and returns one of the coordinates.

**coord\_functions**()

Returns a list of all coordinate functions. For more details see the `base_scalar` method of this class.

**coord\_tuple\_transform\_to**(*to\_sys, coords*)

Transform *coords* to coord system *to\_sys*.

**jacobian**(*sys, coordinates=None*)

Return the jacobian matrix of a transformation on given coordinates. If coordinates are not given, coordinate symbols of *self* are used.

### Parameters

**sys** : `CoordSystem`

**coordinates** : Any iterable, optional.

### Returns

`sympy.ImmutableDenseMatrix`

## Examples

```
>>> from sympy.diffgeom.rn import R2_r, R2_p
>>> R2_p.jacobian(R2_r)
Matrix([
[cos(theta), -rho*sin(theta)],
[sin(theta), rho*cos(theta)]]
>>> R2_p.jacobian(R2_r, [1, 0])
Matrix([
[1, 0],
[0, 1]])
```

**jacobian\_determinant**(*sys*, *coordinates=None*)

Return the jacobian determinant of a transformation on given coordinates. If coordinates are not given, coordinate symbols of *self* are used.

### Parameters

**sys** : CoordSystem

**coordinates** : Any iterable, optional.

### Returns

sympy.Expr

## Examples

```
>>> from sympy.diffgeom.rn import R2_r, R2_p
>>> R2_r.jacobian_determinant(R2_p)
1/sqrt(x**2 + y**2)
>>> R2_r.jacobian_determinant(R2_p, [1, 0])
1
```

**jacobian\_matrix**(*sys*, *coordinates=None*)

Return the jacobian matrix of a transformation on given coordinates. If coordinates are not given, coordinate symbols of *self* are used.

### Parameters

**sys** : CoordSystem

**coordinates** : Any iterable, optional.

### Returns

sympy.ImmutableDenseMatrix

## Examples

```
>>> from sympy.diffgeom.rn import R2_r, R2_p
>>> R2_p.jacobian(R2_r)
Matrix([
[cos(theta), -rho*sin(theta)],
[sin(theta), rho*cos(theta)]]
>>> R2_p.jacobian(R2_r, [1, 0])
```

(continues on next page)

(continued from previous page)

```
Matrix([
[1, 0],
[0, 1]])
```

**point**(*coords*)

Create a Point with coordinates given in this coord system.

**point\_to\_coords**(*point*)

Calculate the coordinates of a point in this coord system.

**transform**(*sys*, *coordinates=None*)

Return the result of coordinate transformation from *self* to *sys*. If coordinates are not given, coordinate symbols of *self* are used.

**Parameters**

**sys** : CoordSystem

**coordinates** : Any iterable, optional.

**Returns**

sympy.ImmutableDenseMatrix containing CoordinateSymbol

### Examples

```
>>> from sympy.diffgeom.rn import R2_r, R2_p
>>> R2_r.transform(R2_p)
Matrix([
[sqrt(x**2 + y**2)],
[atan2(y, x)]]))
>>> R2_r.transform(R2_p, [0, 1])
Matrix([
[1],
[pi/2]])
```

**transformation**(*sys*)

Return coordinate transformation function from *self* to *sys*.

**Parameters**

**sys** : CoordSystem

**Returns**

sympy.Lambda

### Examples

```
>>> from sympy.diffgeom.rn import R2_r, R2_p
>>> R2_r.transformation(R2_p)
Lambda((x, y), Matrix([
[sqrt(x**2 + y**2)],
[atan2(y, x)]]))
```

**class** sympy.diffgeom.CoordinateSymbol(*coord\_sys*, *index*, *\*\*assumptions*)

A symbol which denotes an abstract value of *i*-th coordinate of the coordinate system with given context.

**Parameters**

**coord\_sys** : CoordSystem

**index** : integer

**Explanation**

Each coordinates in coordinate system are represented by unique symbol, such as *x*, *y*, *z* in Cartesian coordinate system.

You may not construct this class directly. Instead, use *symbols* method of CoordSystem.

**Examples**

```
>>> from sympy import symbols, Lambda, Matrix, sqrt, atan2, cos, sin
>>> from sympy.diffgeom import Manifold, Patch, CoordSystem
>>> m = Manifold('M', 2)
>>> p = Patch('P', m)
>>> x, y = symbols('x y', real=True)
>>> r, theta = symbols('r theta', nonnegative=True)
>>> relation_dict = {
... ('Car2D', 'Pol'): Lambda((x, y), Matrix([sqrt(x**2 + y**2), atan2(y,
↳ x)])),
... ('Pol', 'Car2D'): Lambda((r, theta), Matrix([r*cos(theta),
↳ r*sin(theta)]))
... }
>>> Car2D = CoordSystem('Car2D', p, [x, y], relation_dict)
>>> Pol = CoordSystem('Pol', p, [r, theta], relation_dict)
>>> x, y = Car2D.symbols
```

CoordinateSymbol contains its coordinate symbol and index.

```
>>> x.name
'x'
>>> x.coord_sys == Car2D
True
>>> x.index
0
>>> x.is_real
True
```

You can transform CoordinateSymbol into other coordinate system using *rewrite()* method.

```
>>> x.rewrite(Pol)
r*cos(theta)
>>> sqrt(x**2 + y**2).rewrite(Pol).simplify()
r
```

**class** sympy.diffgeom.**Point**(*coord\_sys*, *coords*, **\*\*kwargs**)

Point defined in a coordinate system.

**Parameters**

**coord\_sys** : CoordSystem

**coords** : list

The coordinates of the point.

## Explanation

Mathematically, point is defined in the manifold and does not have any coordinates by itself. Coordinate system is what imbues the coordinates to the point by coordinate chart. However, due to the difficulty of realizing such logic, you must supply a coordinate system and coordinates to define a Point here.

The usage of this object after its definition is independent of the coordinate system that was used in order to define it, however due to limitations in the simplification routines you can arrive at complicated expressions if you use inappropriate coordinate systems.

## Examples

```
>>> from sympy import pi
>>> from sympy.diffgeom import Point
>>> from sympy.diffgeom.rn import R2, R2_r, R2_p
>>> rho, theta = R2_p.symbols
```

```
>>> p = Point(R2_p, [rho, 3*pi/4])
```

```
>>> p.manifold == R2
True
```

```
>>> p.coords()
Matrix([
[rho],
[3*pi/4]])
>>> p.coords(R2_r)
Matrix([
[-sqrt(2)*rho/2],
[sqrt(2)*rho/2]])
```

**coords**(*sys=None*)

Coordinates of the point in given coordinate system. If coordinate system is not passed, it returns the coordinates in the coordinate system in which the poin was defined.

**class** sympy.diffgeom.**BaseScalarField**(*coord\_sys*, *index*, **\*\*kwargs**)

Base scalar field over a manifold for a given coordinate system.

**Parameters**

**coord\_sys** : CoordSystem

**index** : integer

## Explanation

A scalar field takes a point as an argument and returns a scalar. A base scalar field of a coordinate system takes a point and returns one of the coordinates of that point in the coordinate system in question.

To define a scalar field you need to choose the coordinate system and the index of the coordinate.

The use of the scalar field after its definition is independent of the coordinate system in which it was defined, however due to limitations in the simplification routines you may arrive at more complicated expression if you use unappropriate coordinate systems. You can build complicated scalar fields by just building up SymPy expressions containing BaseScalarField instances.

## Examples

```
>>> from sympy import Function, pi
>>> from sympy.diffgeom import BaseScalarField
>>> from sympy.diffgeom.rn import R2_r, R2_p
>>> rho, _ = R2_p.symbols
>>> point = R2_p.point([rho, 0])
>>> fx, fy = R2_r.base_scalars()
>>> ftheta = BaseScalarField(R2_r, 1)
```

```
>>> fx(point)
rho
>>> fy(point)
0
```

```
>>> (fx**2+fy**2).rcall(point)
rho**2
```

```
>>> g = Function('g')
>>> fg = g(ftheta-pi)
>>> fg.rcall(point)
g(-pi)
```

**class** sympy.diffgeom.BaseVectorField(*coord\_sys*, *index*, *\*\*kwargs*)

Base vector field over a manifold for a given coordinate system.

### Parameters

**coord\_sys** : CoordSystem

**index** : integer

## Explanation

A vector field is an operator taking a scalar field and returning a directional derivative (which is also a scalar field). A base vector field is the same type of operator, however the derivation is specifically done with respect to a chosen coordinate.

To define a base vector field you need to choose the coordinate system and the index of the coordinate.

The use of the vector field after its definition is independent of the coordinate system in which it was defined, however due to limitations in the simplification routines you may arrive at more complicated expression if you use inappropriate coordinate systems.

## Examples

```
>>> from sympy import Function
>>> from sympy.diffgeom.rn import R2_p, R2_r
>>> from sympy.diffgeom import BaseVectorField
>>> from sympy import pprint
```

```
>>> x, y = R2_r.symbols
>>> rho, theta = R2_p.symbols
>>> fx, fy = R2_r.base_scalars()
>>> point_p = R2_p.point([rho, theta])
>>> point_r = R2_r.point([x, y])
```

```
>>> g = Function('g')
>>> s_field = g(fx, fy)
```

```
>>> v = BaseVectorField(R2_r, 1)
>>> pprint(v(s_field))
/ d \
|---(g(x, xi))|
\dx /xi=y
>>> pprint(v(s_field).rcall(point_r).doit())
d
--(g(x, y))
dy
>>> pprint(v(s_field).rcall(point_p))
/ d \
|---(g(rho*cos(theta), xi))|
\dx /xi=rho*sin(theta)
```

**class** sympy.diffgeom.Commutator(v1, v2)  
Commutator of two vector fields.

### Explanation

The commutator of two vector fields  $v_1$  and  $v_2$  is defined as the vector field  $[v_1, v_2]$  that evaluated on each scalar field  $f$  is equal to  $v_1(v_2(f)) - v_2(v_1(f))$ .

### Examples

```
>>> from sympy.diffgeom.rn import R2_p, R2_r
>>> from sympy.diffgeom import Commutator
>>> from sympy import simplify
```

```
>>> fx, fy = R2_r.base_scalars()
>>> e_x, e_y = R2_r.base_vectors()
>>> e_r = R2_p.base_vector(0)
```

```
>>> c_xy = Commutator(e_x, e_y)
>>> c_xr = Commutator(e_x, e_r)
>>> c_xy
0
```

Unfortunately, the current code is not able to compute everything:

```
>>> c_xr
Commutator(e_x, e_rho)
>>> simplify(c_xr(fy**2))
-2*cos(theta)*y**2/(x**2 + y**2)
```

**class** sympy.diffgeom.Differential(*form\_field*)

Return the differential (exterior derivative) of a form field.

### Explanation

The differential of a form (i.e. the exterior derivative) has a complicated definition in the general case. The differential  $df$  of the 0-form  $f$  is defined for any vector field  $v$  as  $df(v) = v(f)$ .

### Examples

```
>>> from sympy import Function
>>> from sympy.diffgeom.rn import R2_r
>>> from sympy.diffgeom import Differential
>>> from sympy import pprint
```

```
>>> fx, fy = R2_r.base_scalars()
>>> e_x, e_y = R2_r.base_vectors()
>>> g = Function('g')
>>> s_field = g(fx, fy)
>>> dg = Differential(s_field)
```

```

>>> dg
d(g(x, y))
>>> pprint(dg(e_x))
/ d \
|---(g(xi, y))|
\dx /|xi=x
>>> pprint(dg(e_y))
/ d \
|---(g(x, xi))|
\dx /|xi=y

```

Applying the exterior derivative operator twice always results in:

```

>>> Differential(dg)
0

```

**class** `sympy.diffgeom.TensorProduct(*args)`

Tensor product of forms.

### Explanation

The tensor product permits the creation of multilinear functionals (i.e. higher order tensors) out of lower order fields (e.g. 1-forms and vector fields). However, the higher tensors thus created lack the interesting features provided by the other type of product, the wedge product, namely they are not antisymmetric and hence are not form fields.

### Examples

```

>>> from sympy.diffgeom.rn import R2_r
>>> from sympy.diffgeom import TensorProduct

```

```

>>> fx, fy = R2_r.base_scalars()
>>> e_x, e_y = R2_r.base_vectors()
>>> dx, dy = R2_r.base_oneforms()

```

```

>>> TensorProduct(dx, dy)(e_x, e_y)
1
>>> TensorProduct(dx, dy)(e_y, e_x)
0
>>> TensorProduct(dx, fx*dy)(fx*e_x, e_y)
x**2
>>> TensorProduct(e_x, e_y)(fx**2, fy**2)
4*x*y
>>> TensorProduct(e_y, dx)(fy)
dx

```

You can nest tensor products.

```
>>> tp1 = TensorProduct(dx, dy)
>>> TensorProduct(tp1, dx)(e_x, e_y, e_x)
1
```

You can make partial contraction for instance when ‘raising an index’. Putting `None` in the second argument of `rcall` means that the respective position in the tensor product is left as it is.

```
>>> TP = TensorProduct
>>> metric = TP(dx, dx) + 3*TP(dy, dy)
>>> metric.rcall(e_y, None)
3*dy
```

Or automatically pad the args with `None` without specifying them.

```
>>> metric.rcall(e_y)
3*dy
```

**class** `sympy.diffgeom.WedgeProduct(*args)`

Wedge product of forms.

### Explanation

In the context of integration only completely antisymmetric forms make sense. The wedge product permits the creation of such forms.

### Examples

```
>>> from sympy.diffgeom.rn import R2_r
>>> from sympy.diffgeom import WedgeProduct
```

```
>>> fx, fy = R2_r.base_scalars()
>>> e_x, e_y = R2_r.base_vectors()
>>> dx, dy = R2_r.base_oneforms()
```

```
>>> WedgeProduct(dx, dy)(e_x, e_y)
1
>>> WedgeProduct(dx, dy)(e_y, e_x)
-1
>>> WedgeProduct(dx, fx*dy)(fx*e_x, e_y)
x**2
>>> WedgeProduct(e_x, e_y)(fy, None)
-e_x
```

You can nest wedge products.

```
>>> wp1 = WedgeProduct(dx, dy)
>>> WedgeProduct(wp1, dx)(e_x, e_y, e_x)
0
```

**class** `sympy.diffgeom.LieDerivative(v_field, expr)`  
 Lie derivative with respect to a vector field.

### Explanation

The transport operator that defines the Lie derivative is the pushforward of the field to be derived along the integral curve of the field with respect to which one derives.

### Examples

```
>>> from sympy.diffgeom.rn import R2_r, R2_p
>>> from sympy.diffgeom import (LieDerivative, TensorProduct)
```

```
>>> fx, fy = R2_r.base_scalars()
>>> e_x, e_y = R2_r.base_vectors()
>>> e_rho, e_theta = R2_p.base_vectors()
>>> dx, dy = R2_r.base_oneforms()
```

```
>>> LieDerivative(e_x, fy)
0
>>> LieDerivative(e_x, fx)
1
>>> LieDerivative(e_x, e_x)
0
```

The Lie derivative of a tensor field by another tensor field is equal to their commutator:

```
>>> LieDerivative(e_x, e_rho)
Commutator(e_x, e_rho)
>>> LieDerivative(e_x + e_y, fx)
1
```

```
>>> tp = TensorProduct(dx, dy)
>>> LieDerivative(e_x, tp)
LieDerivative(e_x, TensorProduct(dx, dy))
>>> LieDerivative(e_x, tp)
LieDerivative(e_x, TensorProduct(dx, dy))
```

**class** `sympy.diffgeom.BaseCovarDerivativeOp(coord_sys, index, christoffel)`  
 Covariant derivative operator with respect to a base vector.

### Examples

```
>>> from sympy.diffgeom.rn import R2_r
>>> from sympy.diffgeom import BaseCovarDerivativeOp
>>> from sympy.diffgeom import metric_to_Christoffel_2nd, TensorProduct
```

```
>>> TP = TensorProduct
>>> fx, fy = R2_r.base_scalars()
>>> e_x, e_y = R2_r.base_vectors()
>>> dx, dy = R2_r.base_oneforms()
```

```
>>> ch = metric_to_Christoffel_2nd(TP(dx, dx) + TP(dy, dy))
>>> ch
[[[0, 0], [0, 0]], [[0, 0], [0, 0]]]
>>> cvd = BaseCovarDerivativeOp(R2_r, 0, ch)
>>> cvd(fx)
1
>>> cvd(fx*e_x)
e_x
```

**class** sympy.diffgeom.CovarDerivativeOp(*wrt, christoffel*)  
Covariant derivative operator.

### Examples

```
>>> from sympy.diffgeom.rn import R2_r
>>> from sympy.diffgeom import CovarDerivativeOp
>>> from sympy.diffgeom import metric_to_Christoffel_2nd, TensorProduct
>>> TP = TensorProduct
>>> fx, fy = R2_r.base_scalars()
>>> e_x, e_y = R2_r.base_vectors()
>>> dx, dy = R2_r.base_oneforms()
>>> ch = metric_to_Christoffel_2nd(TP(dx, dx) + TP(dy, dy))
```

```
>>> ch
[[[0, 0], [0, 0]], [[0, 0], [0, 0]]]
>>> cvd = CovarDerivativeOp(fx*e_x, ch)
>>> cvd(fx)
x
>>> cvd(fx*e_x)
x*e_x
```

sympy.diffgeom.intcurve\_series(*vector\_field, param, start\_point, n=6, coord\_sys=None, coeffs=False*)

Return the series expansion for an integral curve of the field.

#### Parameters

##### **vector\_field**

the vector field for which an integral curve will be given

##### **param**

the argument of the function  $\gamma$  from  $R$  to the curve

**start\_point**

the point which corresponds to  $\gamma(0)$

**n**

the order to which to expand

**coord\_sys**

the coordinate system in which to expand coeffs (default False) - if True return a list of elements of the expansion

## Explanation

Integral curve is a function  $\gamma$  taking a parameter in  $R$  to a point in the manifold. It verifies the equation:

$$V(f)(\gamma(t)) = \frac{d}{dt}f(\gamma(t))$$

where the given `vector_field` is denoted as  $V$ . This holds for any value  $t$  for the parameter and any scalar field  $f$ .

This equation can also be decomposed of a basis of coordinate functions  $V(f_i)(\gamma(t)) = \frac{d}{dt}f_i(\gamma(t)) \quad \forall i$

This function returns a series expansion of  $\gamma(t)$  in terms of the coordinate system `coord_sys`. The equations and expansions are necessarily done in coordinate-system-dependent way as there is no other way to represent movement between points on the manifold (i.e. there is no such thing as a difference of points for a general manifold).

## Examples

Use the predefined  $R^2$  manifold:

```
>>> from sympy.abc import t, x, y
>>> from sympy.diffgeom.rn import R2_p, R2_r
>>> from sympy.diffgeom import intcurve_series
```

Specify a starting point and a vector field:

```
>>> start_point = R2_r.point([x, y])
>>> vector_field = R2_r.e_x
```

Calculate the series:

```
>>> intcurve_series(vector_field, t, start_point, n=3)
Matrix([
[t + x],
[y]])
```

Or get the elements of the expansion in a list:

```
>>> series = intcurve_series(vector_field, t, start_point, n=3,
 ↪ coeffs=True)
>>> series[0]
Matrix([
[x],
[y]])
>>> series[1]
Matrix([
[t],
[0]])
>>> series[2]
Matrix([
[0],
[0]])
```

The series in the polar coordinate system:

```
>>> series = intcurve_series(vector_field, t, start_point,
... n=3, coord_sys=R2_p, coeffs=True)
>>> series[0]
Matrix([
[sqrt(x**2 + y**2)],
[atan2(y, x)]]
>>> series[1]
Matrix([
[t*x/sqrt(x**2 + y**2)],
[-t*y/(x**2 + y**2)]]
>>> series[2]
Matrix([
[t**2*(-x**2/(x**2 + y**2)**(3/2) + 1/sqrt(x**2 + y**2))/2],
[t**2*x*y/(x**2 + y**2)**2]])
```

**See also:**

[\*intcurve\\_diffegu\*](#) (page 2816)

`sympy.diffgeom.intcurve_diffegu(vector_field, param, start_point, coord_sys=None)`

Return the differential equation for an integral curve of the field.

**Parameters**

**vector\_field**

the vector field for which an integral curve will be given

**param**

the argument of the function  $\gamma$  from  $\mathbb{R}$  to the curve

**start\_point**

the point which corresponds to  $\gamma(0)$

**coord\_sys**

the coordinate system in which to give the equations

**Returns**

a tuple of (equations, initial conditions)

## Explanation

Integral curve is a function  $\gamma$  taking a parameter in  $R$  to a point in the manifold. It verifies the equation:

$$V(f)(\gamma(t)) = \frac{d}{dt}f(\gamma(t))$$

where the given `vector_field` is denoted as  $V$ . This holds for any value  $t$  for the parameter and any scalar field  $f$ .

This function returns the differential equation of  $\gamma(t)$  in terms of the coordinate system `coord_sys`. The equations and expansions are necessarily done in coordinate-system-dependent way as there is no other way to represent movement between points on the manifold (i.e. there is no such thing as a difference of points for a general manifold).

## Examples

Use the predefined R2 manifold:

```
>>> from sympy.abc import t
>>> from sympy.diffgeom.rn import R2, R2_p, R2_r
>>> from sympy.diffgeom import intcurve_diffequ
```

Specify a starting point and a vector field:

```
>>> start_point = R2_r.point([0, 1])
>>> vector_field = -R2.y*R2.e_x + R2.x*R2.e_y
```

Get the equation:

```
>>> equations, init_cond = intcurve_diffequ(vector_field, t, start_point)
>>> equations
[f_1(t) + Derivative(f_0(t), t), -f_0(t) + Derivative(f_1(t), t)]
>>> init_cond
[f_0(0), f_1(0) - 1]
```

The series in the polar coordinate system:

```
>>> equations, init_cond = intcurve_diffequ(vector_field, t, start_point,
→ R2_p)
>>> equations
[Derivative(f_0(t), t), Derivative(f_1(t), t) - 1]
>>> init_cond
[f_0(0) - 1, f_1(0) - pi/2]
```

### See also:

[`intcurve\_series`](#) (page 2814)

`sympy.diffgeom.vectors_in_basis(expr, to_sys)`

Transform all base vectors in base vectors of a specified coord basis. While the new base vectors are in the new coordinate system basis, any coefficients are kept in the old system.

### Examples

```
>>> from sympy.diffgeom import vectors_in_basis
>>> from sympy.diffgeom.rn import R2_r, R2_p
```

```
>>> vectors_in_basis(R2_r.e_x, R2_p)
-y*e_theta/(x**2 + y**2) + x*e_rho/sqrt(x**2 + y**2)
>>> vectors_in_basis(R2_p.e_r, R2_r)
sin(theta)*e_y + cos(theta)*e_x
```

`sympy.diffgeom.twoform_to_matrix(expr)`

Return the matrix representing the twoform.

For the twoform  $w$  return the matrix  $M$  such that  $M[i, j] = w(e_i, e_j)$ , where  $e_i$  is the  $i$ -th base vector field for the coordinate system in which the expression of  $w$  is given.

### Examples

```
>>> from sympy.diffgeom.rn import R2
>>> from sympy.diffgeom import twoform_to_matrix, TensorProduct
>>> TP = TensorProduct
```

```
>>> twoform_to_matrix(TP(R2.dx, R2.dx) + TP(R2.dy, R2.dy))
Matrix([
[1, 0],
[0, 1]])
>>> twoform_to_matrix(R2.x*TP(R2.dx, R2.dx) + TP(R2.dy, R2.dy))
Matrix([
[x, 0],
[0, 1]])
>>> twoform_to_matrix(TP(R2.dx, R2.dx) + TP(R2.dy, R2.dy) - TP(R2.dx, R2.
→dy)/2)
Matrix([
[1, 0],
[-1/2, 1]])
```

`sympy.diffgeom.metric_to_Christoffel_1st(expr)`

Return the nested list of Christoffel symbols for the given metric. This returns the Christoffel symbol of first kind that represents the Levi-Civita connection for the given metric.

### Examples

```
>>> from sympy.diffgeom.rn import R2
>>> from sympy.diffgeom import metric_to_Christoffel_1st, TensorProduct
>>> TP = TensorProduct
```

```
>>> metric_to_Christoffel_1st(TP(R2.dx, R2.dx) + TP(R2.dy, R2.dy))
[[[0, 0], [0, 0]], [[0, 0], [0, 0]]]
```

(continues on next page)

(continued from previous page)

```
>>> metric_to_Christoffel_1st(R2.x*TP(R2.dx, R2.dx) + TP(R2.dy, R2.dy))
[[[1/2, 0], [0, 0]], [[0, 0], [0, 0]]]
```

`sympy.diffgeom.metric_to_Christoffel_2nd(expr)`

Return the nested list of Christoffel symbols for the given metric. This returns the Christoffel symbol of second kind that represents the Levi-Civita connection for the given metric.

### Examples

```
>>> from sympy.diffgeom.rn import R2
>>> from sympy.diffgeom import metric_to_Christoffel_2nd, TensorProduct
>>> TP = TensorProduct
```

```
>>> metric_to_Christoffel_2nd(TP(R2.dx, R2.dx) + TP(R2.dy, R2.dy))
[[[0, 0], [0, 0]], [[0, 0], [0, 0]]]
>>> metric_to_Christoffel_2nd(R2.x*TP(R2.dx, R2.dx) + TP(R2.dy, R2.dy))
[[[1/(2*x), 0], [0, 0]], [[0, 0], [0, 0]]]
```

`sympy.diffgeom.metric_to_Riemann_components(expr)`

Return the components of the Riemann tensor expressed in a given basis.

Given a metric it calculates the components of the Riemann tensor in the canonical basis of the coordinate system in which the metric expression is given.

### Examples

```
>>> from sympy import exp
>>> from sympy.diffgeom.rn import R2
>>> from sympy.diffgeom import metric_to_Riemann_components,
↳ TensorProduct
>>> TP = TensorProduct
```

```
>>> metric_to_Riemann_components(TP(R2.dx, R2.dx) + TP(R2.dy, R2.dy))
[[[[0, 0], [0, 0]], [[0, 0], [0, 0]]], [[[[0, 0], [0, 0]], [[0, 0], [0,
↳ 0]]]]]
>>> non_trivial_metric = exp(2*R2.r)*TP(R2.dr, R2.dr) + R2.
↳ r**2*TP(R2.dtheta, R2.dtheta)
>>> non_trivial_metric
exp(2*rho)*TensorProduct(drho, drho) + rho**2*TensorProduct(dtheta,
↳ dtheta)
>>> riemann = metric_to_Riemann_components(non_trivial_metric)
>>> riemann[0, :, :, :]
[[[0, 0], [0, 0]], [[0, exp(-2*rho)*rho], [-exp(-2*rho)*rho, 0]]]
>>> riemann[1, :, :, :]
[[[0, -1/rho], [1/rho, 0]], [[0, 0], [0, 0]]]
```

`sympy.diffgeom.metric_to_Ricci_components(expr)`

Return the components of the Ricci tensor expressed in a given basis.

Given a metric it calculates the components of the Ricci tensor in the canonical basis of the coordinate system in which the metric expression is given.

### Examples

```
>>> from sympy import exp
>>> from sympy.diffgeom.Rn import R2
>>> from sympy.diffgeom import metric_to_Ricci_components, TensorProduct
>>> TP = TensorProduct
```

```
>>> metric_to_Ricci_components(TP(R2.dx, R2.dx) + TP(R2.dy, R2.dy))
[[0, 0], [0, 0]]
>>> non_trivial_metric = exp(2*R2.r)*TP(R2.dr, R2.dr) +
→ R2.r**2*TP(R2.dtheta, R2.dtheta)
>>> non_trivial_metric
exp(2*rho)*TensorProduct(drho, drho) + rho**2*TensorProduct(dtheta,
→dtheta)
>>> metric_to_Ricci_components(non_trivial_metric)
[[1/rho, 0], [0, exp(-2*rho)*rho]]
```

## Plotting

### Introduction

The plotting module allows you to make 2-dimensional and 3-dimensional plots. Presently the plots are rendered using `matplotlib` as a backend. It is also possible to plot 2-dimensional plots using a *TextBackend* (page 2869) if you do not have `matplotlib`.

The plotting module has the following functions:

- `plot()` (page 2825): Plots 2D line plots.
- `plot_parametric()` (page 2828): Plots 2D parametric plots.
- `plot_implicit()` (page 2847): Plots 2D implicit and region plots.
- `plot3d()` (page 2838): Plots 3D plots of functions in two variables.
- `plot3d_parametric_line()` (page 2839): Plots 3D line plots, defined by a parameter.
- `plot3d_parametric_surface()` (page 2846): Plots 3D parametric surface plots.

The above functions are only for convenience and ease of use. It is possible to plot any plot by passing the corresponding *Series* class to *Plot* (page 2821) as argument.

## Plot Class

```
class sympy.plotting.plot.Plot(*args, title=None, xlabel=None, ylabel=None,
 ylabel=None, aspect_ratio='auto', xlim=None,
 ylim=None, axis_center='auto', axis=True,
 xscale='linear', yscale='linear', legend=False,
 autoscale=True, margin=0, annotations=None,
 markers=None, rectangles=None, fill=None,
 backend='default', size=None, **kwargs)
```

The central class of the plotting module.

## Explanation

For interactive work the function `plot()` (page 2825) is better suited.

This class permits the plotting of SymPy expressions using numerous backends (`matplotlib`, `textplot`, the old `pyglet` module for SymPy, Google charts api, etc).

The figure can contain an arbitrary number of plots of SymPy expressions, lists of coordinates of points, etc. Plot has a private attribute `_series` that contains all data series to be plotted (expressions for lines or surfaces, lists of points, etc (all subclasses of `BaseSeries`)). Those data series are instances of classes not imported by `from sympy import *`.

The customization of the figure is on two levels. Global options that concern the figure as a whole (e.g. title, xlabel, scale, etc) and per-data series options (e.g. name) and aesthetics (e.g. color, point shape, line type, etc.).

The difference between options and aesthetics is that an aesthetic can be a function of the coordinates (or parameters in a parametric plot). The supported values for an aesthetic are:

- None (the backend uses default values)
- a constant
- a function of one variable (the first coordinate or parameter)
- a function of two variables (the first and second coordinate or parameters)
- a function of three variables (only in nonparametric 3D plots)

Their implementation depends on the backend so they may not work in some backends.

If the plot is parametric and the arity of the aesthetic function permits it the aesthetic is calculated over parameters and not over coordinates. If the arity does not permit calculation over parameters the calculation is done over coordinates.

Only cartesian coordinates are supported for the moment, but you can use the parametric plots to plot in polar, spherical and cylindrical coordinates.

The arguments for the constructor `Plot` must be subclasses of `BaseSeries`.

Any global option can be specified as a keyword argument.

The global options for a figure are:

- title : str
- xlabel : str or Symbol

- `ylabel` : str or Symbol
- `zlabel` : str or Symbol
- `legend` : bool
- `xscale` : {'linear', 'log'}
- `yscale` : {'linear', 'log'}
- `axis` : bool
- `axis_center` : tuple of two floats or {'center', 'auto'}
- `xlim` : tuple of two floats
- `ylim` : tuple of two floats
- `aspect_ratio` : tuple of two floats or {'auto'}
- `autoscale` : bool
- `margin` : float in [0, 1]
- `backend` : {'default', 'matplotlib', 'text'} or a subclass of BaseBackend
- `size` : optional tuple of two floats, (width, height); default: None

The per data series options and aesthetics are: There are none in the base series. See below for options for subclasses.

Some data series support additional aesthetics or options:

[LineOver1DRangeSeries](#) (page 2866), [Parametric2DLineSeries](#) (page 2866), and [Parametric3DLineSeries](#) (page 2867) support the following:

Aesthetics:

- **line\_color**  
[string, or float, or function, optional] Specifies the color for the plot, which depends on the backend being used.

For example, if MatplotlibBackend is being used, then Matplotlib string colors are acceptable ("red", "r", "cyan", "c", ...). Alternatively, we can use a float number,  $0 < \text{color} < 1$ , wrapped in a string (for example, `line_color="0.5"`) to specify grayscale colors. Alternatively, We can specify a function returning a single float value: this will be used to apply a color-loop (for example, `line_color=lambda x: math.cos(x)`).

Note that by setting `line_color`, it would be applied simultaneously to all the series.

Options:

- `label` : str
- `steps` : bool
- `integers_only` : bool

[SurfaceOver2DRangeSeries](#) (page 2867) and [ParametricSurfaceSeries](#) (page 2867) support the following:

Aesthetics:

- `surface_color` : function which returns a float.

**append(*arg*)**

Adds an element from a plot's series to an existing plot.

**Examples**

Consider two Plot objects, p1 and p2. To add the second plot's first series object to the first, use the append method, like so:

```
>>> from sympy import symbols
>>> from sympy.plotting import plot
>>> x = symbols('x')
>>> p1 = plot(x*x, show=False)
>>> p2 = plot(x, show=False)
>>> p1.append(p2[0])
>>> p1
Plot object containing:
[0]: cartesian line: x**2 for x over (-10.0, 10.0)
[1]: cartesian line: x for x over (-10.0, 10.0)
>>> p1.show()
```

**See also:**

[extend](#) (page 2823)

**extend(*arg*)**

Adds all series from another plot.

**Examples**

Consider two Plot objects, p1 and p2. To add the second plot to the first, use the extend method, like so:

```
>>> from sympy import symbols
>>> from sympy.plotting import plot
>>> x = symbols('x')
>>> p1 = plot(x**2, show=False)
>>> p2 = plot(x, -x, show=False)
>>> p1.extend(p2)
>>> p1
Plot object containing:
[0]: cartesian line: x**2 for x over (-10.0, 10.0)
[1]: cartesian line: x for x over (-10.0, 10.0)
[2]: cartesian line: -x for x over (-10.0, 10.0)
>>> p1.show()
```

## Plotting Function Reference

`sympy.plotting.plot.plot(*args, show=True, **kwargs)`

Plots a function of a single variable as a curve.

### Parameters

#### **args :**

The first argument is the expression representing the function of single variable to be plotted.

The last argument is a 3-tuple denoting the range of the free variable. e.g.  $(x, 0, 5)$

Typical usage examples are in the followings:

- **Plotting a single expression with a single range.**  
`plot(expr, range, **kwargs)`
- **Plotting a single expression with the default range (-10, 10).**  
`plot(expr, **kwargs)`
- **Plotting multiple expressions with a single range.**  
`plot(expr1, expr2, ..., range, **kwargs)`
- **Plotting multiple expressions with multiple ranges.**  
`plot((expr1, range1), (expr2, range2), ..., **kwargs)`

It is best practice to specify range explicitly because default range may change in the future if a more advanced default range detection algorithm is implemented.

**show** : bool, optional

The default value is set to True. Set show to False and the function will not display the plot. The returned instance of the Plot class can then be used to save or display the plot by calling the `save()` and `show()` methods respectively.

**line\_color** : string, or float, or function, optional

Specifies the color for the plot. See Plot to see how to set color for the plots. Note that by setting `line_color`, it would be applied simultaneously to all the series.

**title** : str, optional

Title of the plot. It is set to the latex representation of the expression, if the plot has only one expression.

**label** : str, optional

The label of the expression in the plot. It will be used when called with `legend`. Default is the name of the expression. e.g.  $\sin(x)$

**xlabel** : str or expression, optional

Label for the x-axis.

**ylabel** : str or expression, optional

Label for the y-axis.

**xscale** : 'linear' or 'log', optional

Sets the scaling of the x-axis.

**yscale** : 'linear' or 'log', optional

Sets the scaling of the y-axis.

**axis\_center** : (float, float), optional

Tuple of two floats denoting the coordinates of the center or {'center', 'auto'}

**xlim** : (float, float), optional

Denotes the x-axis limits, (min, max)`.

**ylim** : (float, float), optional

Denotes the y-axis limits, (min, max)`.

**annotations** : list, optional

A list of dictionaries specifying the type of annotation required. The keys in the dictionary should be equivalent to the arguments of the `matplotlib`'s `annotate()` method.

**markers** : list, optional

A list of dictionaries specifying the type the markers required. The keys in the dictionary should be equivalent to the arguments of the `matplotlib`'s `plot()` function along with the marker related key-worded arguments.

**rectangles** : list, optional

A list of dictionaries specifying the dimensions of the rectangles to be plotted. The keys in the dictionary should be equivalent to the arguments of the `matplotlib`'s `Rectangle` class.

**fill** : dict, optional

A dictionary specifying the type of color filling required in the plot. The keys in the dictionary should be equivalent to the arguments of the `matplotlib`'s `fill_between()` method.

**adaptive** : bool, optional

The default value is set to True. Set adaptive to False and specify `nb_of_points` if uniform sampling is required.

The plotting uses an adaptive algorithm which samples recursively to accurately plot. The adaptive algorithm uses a random point near the midpoint of two points that has to be further sampled. Hence the same plots can appear slightly different.

**depth** : int, optional

Recursion depth of the adaptive algorithm. A depth of value  $n$  samples a maximum of  $2^n$  points.

If the adaptive flag is set to False, this will be ignored.

**nb\_of\_points** : int, optional

Used when the adaptive is set to False. The function is uniformly sampled at `nb_of_points` number of points.

If the adaptive flag is set to True, this will be ignored.

**size** : (float, float), optional

A tuple in the form (width, height) in inches to specify the size of the overall figure. The default value is set to None, meaning the size will be set by the default backend.

## Examples

```
>>> from sympy import symbols
>>> from sympy.plotting import plot
>>> x = symbols('x')
```

Single Plot

```
>>> plot(x**2, (x, -5, 5))
Plot object containing:
[0]: cartesian line: x**2 for x over (-5.0, 5.0)
```

Multiple plots with single range.

```
>>> plot(x, x**2, x**3, (x, -5, 5))
Plot object containing:
[0]: cartesian line: x for x over (-5.0, 5.0)
[1]: cartesian line: x**2 for x over (-5.0, 5.0)
[2]: cartesian line: x**3 for x over (-5.0, 5.0)
```

Multiple plots with different ranges.

```
>>> plot((x**2, (x, -6, 6)), (x, (x, -5, 5)))
Plot object containing:
[0]: cartesian line: x**2 for x over (-6.0, 6.0)
[1]: cartesian line: x for x over (-5.0, 5.0)
```

No adaptive sampling.

```
>>> plot(x**2, adaptive=False, nb_of_points=400)
Plot object containing:
[0]: cartesian line: x**2 for x over (-10.0, 10.0)
```

**See also:**

[Plot](#) (page 2821), [LineOver1DRangeSeries](#) (page 2866)

`sympy.plotting.plot.plot_parametric(*args, show=True, **kwargs)`

Plots a 2D parametric curve.

**Parameters****args**

Common specifications are:

- **Plotting a single parametric curve with a range**  
`plot_parametric((expr_x, expr_y), range)`
- **Plotting multiple parametric curves with the same range**  
`plot_parametric((expr_x, expr_y), ..., range)`
- **Plotting multiple parametric curves with different ranges**  
`plot_parametric((expr_x, expr_y, range), ...)`

`expr_x` is the expression representing  $x$  component of the parametric function.

`expr_y` is the expression representing  $y$  component of the parametric function.

`range` is a 3-tuple denoting the parameter symbol, start and stop. For example, `(u, 0, 5)`.

If the range is not specified, then a default range of `(-10, 10)` is used.

However, if the arguments are specified as `(expr_x, expr_y, range), ...,` you must specify the ranges for each expressions manually.

Default range may change in the future if a more advanced algorithm is implemented.

**adaptive** : bool, optional

Specifies whether to use the adaptive sampling or not.

The default value is set to `True`. Set `adaptive` to `False` and specify `nb_of_points` if uniform sampling is required.

**depth** : int, optional

The recursion depth of the adaptive algorithm. A depth of value  $n$  samples a maximum of  $2^n$  points.

**nb\_of\_points** : int, optional

Used when the `adaptive` flag is set to `False`.

Specifies the number of the points used for the uniform sampling.

**line\_color** : string, or float, or function, optional

Specifies the color for the plot. See `Plot` to see how to set color for the plots. Note that by setting `line_color`, it would be applied simultaneously to all the series.

**label** : str, optional

The label of the expression in the plot. It will be used when called with `legend`. Default is the name of the expression. e.g. `sin(x)`

**xlabel** : str, optional

Label for the x-axis.

**ylabel** : str, optional

Label for the y-axis.

**xscale** : 'linear' or 'log', optional

Sets the scaling of the x-axis.

**yscale** : 'linear' or 'log', optional

Sets the scaling of the y-axis.

**axis\_center** : (float, float), optional

Tuple of two floats denoting the coordinates of the center or {'center', 'auto'}

**xlim** : (float, float), optional

Denotes the x-axis limits, (min, max)`.

**ylim** : (float, float), optional

Denotes the y-axis limits, (min, max)`.

**size** : (float, float), optional

A tuple in the form (width, height) in inches to specify the size of the overall figure. The default value is set to None, meaning the size will be set by the default backend.

## Examples

```
>>> from sympy import plot_parametric, symbols, cos, sin
>>> u = symbols('u')
```

A parametric plot with a single expression:

```
>>> plot_parametric((cos(u), sin(u)), (u, -5, 5))
Plot object containing:
[0]: parametric cartesian line: (cos(u), sin(u)) for u over (-5.0, 5.0)
```

A parametric plot with multiple expressions with the same range:

```
>>> plot_parametric((cos(u), sin(u)), (u, cos(u)), (u, -10, 10))
Plot object containing:
[0]: parametric cartesian line: (cos(u), sin(u)) for u over (-10.0, 10.0)
[1]: parametric cartesian line: (u, cos(u)) for u over (-10.0, 10.0)
```

A parametric plot with multiple expressions with different ranges for each curve:

```
>>> plot_parametric((cos(u), sin(u), (u, -5, 5)),
... (cos(u), u, (u, -5, 5)))
Plot object containing:
[0]: parametric cartesian line: (cos(u), sin(u)) for u over (-5.0, 5.0)
[1]: parametric cartesian line: (cos(u), u) for u over (-5.0, 5.0)
```

## Notes

The plotting uses an adaptive algorithm which samples recursively to accurately plot the curve. The adaptive algorithm uses a random point near the midpoint of two points that has to be further sampled. Hence, repeating the same plot command can give slightly different results because of the random sampling.

If there are multiple plots, then the same optional arguments are applied to all the plots drawn in the same canvas. If you want to set these options separately, you can index the returned Plot object and set it.

For example, when you specify `line_color` once, it would be applied simultaneously to both series.

```
>>> from sympy import pi
>>> expr1 = (u, cos(2*pi*u)/2 + 1/2)
>>> expr2 = (u, sin(2*pi*u)/2 + 1/2)
>>> p = plot_parametric(expr1, expr2, (u, 0, 1), line_color='blue')
```

If you want to specify the line color for the specific series, you should index each item and apply the property manually.

```
>>> p[0].line_color = 'red'
>>> p.show()
```

**See also:**

[Plot](#) (page 2821), [Parametric2DLineSeries](#) (page 2866)

`sympy.plotting.plot.plot3d(*args, show=True, **kwargs)`

Plots a 3D surface plot.

**Usage**

Single plot

`plot3d(expr, range_x, range_y, **kwargs)`

If the ranges are not specified, then a default range of (-10, 10) is used.

Multiple plot with the same range.

`plot3d(expr1, expr2, range_x, range_y, **kwargs)`

If the ranges are not specified, then a default range of (-10, 10) is used.

Multiple plots with different ranges.

`plot3d((expr1, range_x, range_y), (expr2, range_x, range_y), ..., **kwargs)`

Ranges have to be specified for every expression.

Default range may change in the future if a more advanced default range detection algorithm is implemented.

**Arguments**

`expr` : Expression representing the function along x.

**`range_x`**

[[Symbol](#) (page 976), float, float)] A 3-tuple denoting the range of the x variable, e.g. (x, 0, 5).

**`range_y`**

[[Symbol](#) (page 976), float, float)] A 3-tuple denoting the range of the y variable, e.g. (y, 0, 5).

**Keyword Arguments**

Arguments for `SurfaceOver2DRangeSeries` class:

**`nb_of_points_x`**

[int] The x range is sampled uniformly at `nb_of_points_x` of points.

**`nb_of_points_y`**

[int] The y range is sampled uniformly at `nb_of_points_y` of points.

Aesthetics:

**`surface_color`**

[Function which returns a float] Specifies the color for the surface of the plot. See [Plot](#) (page 2821) for more details.

If there are multiple plots, then the same series arguments are applied to all the plots. If you want to set these options separately, you can index the returned Plot object and set it.

Arguments for Plot class:

**title**

[str] Title of the plot.

**size**

[(float, float), optional] A tuple in the form (width, height) in inches to specify the size of the overall figure. The default value is set to None, meaning the size will be set by the default backend.

## Examples

```
>>> from sympy import symbols
>>> from sympy.plotting import plot3d
>>> x, y = symbols('x y')
```

Single plot

```
>>> plot3d(x*y, (x, -5, 5), (y, -5, 5))
Plot object containing:
[0]: cartesian surface: x*y for x over (-5.0, 5.0) and y over (-5.0, 5.0)
```

Multiple plots with same range

```
>>> plot3d(x*y, -x*y, (x, -5, 5), (y, -5, 5))
Plot object containing:
[0]: cartesian surface: x*y for x over (-5.0, 5.0) and y over (-5.0, 5.0)
[1]: cartesian surface: -x*y for x over (-5.0, 5.0) and y over (-5.0, 5.0)
→0)
```

Multiple plots with different ranges.

```
>>> plot3d((x**2 + y**2, (x, -5, 5), (y, -5, 5)),
... (x*y, (x, -3, 3), (y, -3, 3)))
Plot object containing:
[0]: cartesian surface: x**2 + y**2 for x over (-5.0, 5.0) and y over (-5.0, 5.0)
→5.0, 5.0)
[1]: cartesian surface: x*y for x over (-3.0, 3.0) and y over (-3.0, 3.0)
```

**See also:**

[Plot](#) (page 2821), [SurfaceOver2DRangeSeries](#) (page 2867)

`sympy.plotting.plot.plot3d_parametric_line(*args, show=True, **kwargs)`

Plots a 3D parametric line plot.

## Usage

Single plot:

```
plot3d_parametric_line(expr_x, expr_y, expr_z, range, **kwargs)
```

If the range is not specified, then a default range of (-10, 10) is used.

Multiple plots.

```
plot3d_parametric_line((expr_x, expr_y, expr_z, range), ..., **kwargs)
```

Ranges have to be specified for every expression.

Default range may change in the future if a more advanced default range detection algorithm is implemented.

## Arguments

`expr_x` : Expression representing the function along x.

`expr_y` : Expression representing the function along y.

`expr_z` : Expression representing the function along z.

### **range**

`[(Symbol (page 976), float, float)]` A 3-tuple denoting the range of the parameter variable, e.g., (u, 0, 5).

## Keyword Arguments

Arguments for Parametric3DLineSeries class.

`nb_of_points` : The range is uniformly sampled at `nb_of_points` number of points.

Aesthetics:

### **line\_color**

`[string, or float, or function, optional]` Specifies the color for the plot. See Plot to see how to set color for the plots. Note that by setting `line_color`, it would be applied simultaneously to all the series.

### **label**

`[str]` The label to the plot. It will be used when called with `legend=True` to denote the function with the given label in the plot.

If there are multiple plots, then the same series arguments are applied to all the plots. If you want to set these options separately, you can index the returned Plot object and set it.

Arguments for Plot class.

### **title**

`[str]` Title of the plot.

### **size**

`[(float, float), optional]` A tuple in the form (width, height) in inches to specify the size of the overall figure. The default value is set to None, meaning the size will be set by the default backend.

## Examples

```
>>> from sympy import symbols, cos, sin
>>> from sympy.plotting import plot3d_parametric_line
>>> u = symbols('u')
```

Single plot.

```
>>> plot3d_parametric_line(cos(u), sin(u), u, (u, -5, 5))
Plot object containing:
[0]: 3D parametric cartesian line: (cos(u), sin(u), u) for u over (-5.0, 5.0)
```

Multiple plots.

```
>>> plot3d_parametric_line((cos(u), sin(u), u, (u, -5, 5)),
... (sin(u), u**2, u, (u, -5, 5)))
Plot object containing:
[0]: 3D parametric cartesian line: (cos(u), sin(u), u) for u over (-5.0, 5.0)
[1]: 3D parametric cartesian line: (sin(u), u**2, u) for u over (-5.0, 5.0)
```

**See also:**

[Plot](#) (page 2821), [Parametric3DLineSeries](#) (page 2867)

`sympy.plotting.plot.plot3d_parametric_surface(*args, show=True, **kwargs)`

Plots a 3D parametric surface plot.

**Explanation**

Single plot.

```
plot3d_parametric_surface(expr_x, expr_y, expr_z, range_u, range_v,
**kwargs)
```

If the ranges is not specified, then a default range of (-10, 10) is used.

Multiple plots.

```
plot3d_parametric_surface((expr_x, expr_y, expr_z, range_u, range_v), ...
, **kwargs)
```

Ranges have to be specified for every expression.

Default range may change in the future if a more advanced default range detection algorithm is implemented.

**Arguments**

`expr_x` : Expression representing the function along x.

`expr_y` : Expression representing the function along y.

`expr_z` : Expression representing the function along z.

**`range_u`**

[Symbol](#) (page 976), float, float)] A 3-tuple denoting the range of the u variable, e.g. (u, 0, 5).

**`range_v`**

[Symbol](#) (page 976), float, float)] A 3-tuple denoting the range of the v variable, e.g. (v, 0, 5).

**Keyword Arguments**

Arguments for ParametricSurfaceSeries class:

**`nb_of_points_u`**

[int] The u range is sampled uniformly at nb\_of\_points\_v of points

**`nb_of_points_y`**

[int] The v range is sampled uniformly at nb\_of\_points\_y of points

Aesthetics:

**`surface_color`**

[Function which returns a float] Specifies the color for the surface of the plot. See [Plot](#) (page 2821) for more details.

If there are multiple plots, then the same series arguments are applied for all the plots. If you want to set these options separately, you can index the returned Plot object and set it.

Arguments for Plot class:

#### title

[str] Title of the plot.

#### size

[(float, float), optional] A tuple in the form (width, height) in inches to specify the size of the overall figure. The default value is set to None, meaning the size will be set by the default backend.

### Examples

```
>>> from sympy import symbols, cos, sin
>>> from sympy.plotting import plot3d_parametric_surface
>>> u, v = symbols('u v')
```

Single plot.

```
>>> plot3d_parametric_surface(cos(u + v), sin(u - v), u - v,
... (u, -5, 5), (v, -5, 5))
Plot object containing:
[0]: parametric cartesian surface: (cos(u + v), sin(u - v), u - v) for u
→ over (-5.0, 5.0) and v over (-5.0, 5.0)
```

#### See also:

[Plot](#) (page 2821), [ParametricSurfaceSeries](#) (page 2867)

```
sympy.plotting.plot_implicit.plot_implicit(expr, x_var=None, y_var=None,
 adaptive=True, depth=0, points=300,
 line_color='blue', show=True, **kwargs)
```

A plot function to plot implicit equations / inequalities.

### Arguments

- `expr` : The equation / inequality that is to be plotted.
- `x_var` (optional) : symbol to plot on x-axis or tuple giving symbol and range as (symbol, xmin, xmax)
- `y_var` (optional) : symbol to plot on y-axis or tuple giving symbol and range as (symbol, ymin, ymax)

If neither `x_var` nor `y_var` are given then the free symbols in the expression will be assigned in the order they are sorted.

The following keyword arguments can also be used:

- **adaptive Boolean. The default value is set to True. It has to be** set to False if you want to use a mesh grid.
- **depth integer. The depth of recursion for adaptive mesh grid.** Default value is 0. Takes value in the range (0, 4).

- **points integer.** The number of points if adaptive mesh grid is not used. Default value is 300.
- **show Boolean.** Default value is True. If set to False, the plot will not be shown. See Plot for further information.
- **title string.** The title for the plot.
- **xlabel string.** The label for the x-axis
- **ylabel string.** The label for the y-axis

Aesthetics options:

- **line\_color: float or string.** Specifies the color for the plot.  
See Plot to see how to set color for the plots. Default value is “Blue”

plot\_implicit, by default, uses interval arithmetic to plot functions. If the expression cannot be plotted using interval arithmetic, it defaults to a generating a contour using a mesh grid of fixed number of points. By setting adaptive to False, you can force plot\_implicit to use the mesh grid. The mesh grid method can be effective when adaptive plotting using interval arithmetic, fails to plot with small line width.

## Examples

Plot expressions:

```
>>> from sympy import plot_implicit, symbols, Eq, And
>>> x, y = symbols('x y')
```

Without any ranges for the symbols in the expression:

```
>>> p1 = plot_implicit(Eq(x**2 + y**2, 5))
```

With the range for the symbols:

```
>>> p2 = plot_implicit(
... Eq(x**2 + y**2, 3), (x, -3, 3), (y, -3, 3))
```

With depth of recursion as argument:

```
>>> p3 = plot_implicit(
... Eq(x**2 + y**2, 5), (x, -4, 4), (y, -4, 4), depth = 2)
```

Using mesh grid and not using adaptive meshing:

```
>>> p4 = plot_implicit(
... Eq(x**2 + y**2, 5), (x, -5, 5), (y, -2, 2),
... adaptive=False)
```

Using mesh grid without using adaptive meshing with number of points specified:

```
>>> p5 = plot_implicit(
... Eq(x**2 + y**2, 5), (x, -5, 5), (y, -2, 2),
... adaptive=False, points=400)
```

Plotting regions:

```
>>> p6 = plot_implicit(y > x**2)
```

Plotting Using boolean conjunctions:

```
>>> p7 = plot_implicit(And(y > x, y > -x))
```

When plotting an expression with a single variable ( $y - 1$ , for example), specify the  $x$  or the  $y$  variable explicitly:

```
>>> p8 = plot_implicit(y - 1, y_var=y)
>>> p9 = plot_implicit(x - 1, x_var=x)
```

## PlotGrid Class

```
class sympy.plotting.plot.PlotGrid(nrows, ncolumns, *args, show=True, size=None,
 **kwargs)
```

This class helps to plot subplots from already created SymPy plots in a single figure.

## Examples

```
>>> from sympy import symbols
>>> from sympy.plotting import plot, plot3d, PlotGrid
>>> x, y = symbols('x, y')
>>> p1 = plot(x, x**2, x**3, (x, -5, 5))
>>> p2 = plot((x**2, (x, -6, 6)), (x, (x, -5, 5)))
>>> p3 = plot(x**3, (x, -5, 5))
>>> p4 = plot3d(x*y, (x, -5, 5), (y, -5, 5))
```

Plotting vertically in a single line:

```
>>> PlotGrid(2, 1, p1, p2)
PlotGrid object containing:
Plot[0]:Plot object containing:
[0]: cartesian line: x for x over (-5.0, 5.0)
[1]: cartesian line: x**2 for x over (-5.0, 5.0)
[2]: cartesian line: x**3 for x over (-5.0, 5.0)
Plot[1]:Plot object containing:
[0]: cartesian line: x**2 for x over (-6.0, 6.0)
[1]: cartesian line: x for x over (-5.0, 5.0)
```

Plotting horizontally in a single line:

```
>>> PlotGrid(1, 3, p2, p3, p4)
PlotGrid object containing:
Plot[0]:Plot object containing:
[0]: cartesian line: x^2 for x over $(-6.0, 6.0)$
[1]: cartesian line: x for x over $(-5.0, 5.0)$
Plot[1]:Plot object containing:
[0]: cartesian line: x^3 for x over $(-5.0, 5.0)$
Plot[2]:Plot object containing:
[0]: cartesian surface: $x*y$ for x over $(-5.0, 5.0)$ and y over $(-5.0, 5.0)$
```

Plotting in a grid form:

```
>>> PlotGrid(2, 2, p1, p2, p3, p4)
PlotGrid object containing:
Plot[0]:Plot object containing:
[0]: cartesian line: x for x over $(-5.0, 5.0)$
[1]: cartesian line: x^2 for x over $(-5.0, 5.0)$
[2]: cartesian line: x^3 for x over $(-5.0, 5.0)$
Plot[1]:Plot object containing:
[0]: cartesian line: x^2 for x over $(-6.0, 6.0)$
[1]: cartesian line: x for x over $(-5.0, 5.0)$
Plot[2]:Plot object containing:
[0]: cartesian line: x^3 for x over $(-5.0, 5.0)$
```

(continues on next page)

(continued from previous page)

```
Plot[3]:Plot object containing:
[0]: cartesian surface: x*y for x over (-5.0, 5.0) and y over (-5.0, 5.0)
```

## Series Classes

**class** sympy.plotting.plot.BaseSeries

Base class for the data objects containing stuff to be plotted.

## Explanation

The backend should check if it supports the data series that is given. (e.g. TextBackend supports only LineOver1DRangeSeries). It is the backend responsibility to know how to use the class of data series that is given.

Some data series classes are grouped (using a class attribute like `is_2Dline`) according to the api they present (based only on convention). The backend is not obliged to use that api (e.g. `LineOver1DRangeSeries` belongs to the `is_2Dline` group and presents the `get_points` method, but the `TextBackend` does not use the `get_points` method).

**class** sympy.plotting.plot.Line2DBaseSeries

A base class for 2D lines.

- adding the label, steps and only\_integers options
- making is\_2Dline true
- defining get\_segments and get\_color\_array

**get\_data()**

Return lists of coordinates for plotting the line.

**Returns**

**x** : list

List of x-coordinates

**y**

[list] List of y-coordinates

**z**

[list] List of z-coordinates in case of Parametric3DLineSeries

**class** sympy.plotting.plot.LineOver1DRangeSeries(*expr, var\_start\_end, \*\*kwargs*)

Representation for a line consisting of a SymPy expression over a range.

**get\_points()**

Return lists of coordinates for plotting. Depending on the `adaptive` option, this function will either use an adaptive algorithm or it will uniformly sample the expression over the provided range.

**Returns**

**x** : list

List of x-coordinates

**y**

[list] List of y-coordinates

**Explanation**

The adaptive sampling is done by recursively checking if three points are almost collinear. If they are not collinear, then more points are added between those points.

**References**

[R692]

**class** sympy.plotting.plot.Parametric2DLineSeries(*expr\_x, expr\_y, var\_start\_end, \*\*kwargs*)

Representation for a line consisting of two parametric SymPy expressions over a range.

**get\_points()**

Return lists of coordinates for plotting. Depending on the `adaptive` option, this function will either use an adaptive algorithm or it will uniformly sample the expression over the provided range.

**Returns**

**x** : list

List of x-coordinates

**y**

[list] List of y-coordinates

**Explanation**

The adaptive sampling is done by recursively checking if three points are almost collinear. If they are not collinear, then more points are added between those points.

**References**

[R693]

**class** `sympy.plotting.plot.Line3DBaseSeries`

A base class for 3D lines.

Most of the stuff is derived from `Line2DBaseSeries`.

**class** `sympy.plotting.plot.Parametric3DLineSeries(expr_x, expr_y, expr_z, var_start_end, **kwargs)`

Representation for a 3D line consisting of three parametric SymPy expressions and a range.

**class** `sympy.plotting.plot.SurfaceBaseSeries`

A base class for 3D surfaces.

**class** `sympy.plotting.plot.SurfaceOver2DRangeSeries(expr, var_start_end_x, var_start_end_y, **kwargs)`

Representation for a 3D surface consisting of a SymPy expression and 2D range.

**class** `sympy.plotting.plot.ParametricSurfaceSeries(expr_x, expr_y, expr_z, var_start_end_u, var_start_end_v, **kwargs)`

Representation for a 3D surface consisting of three parametric SymPy expressions and a range.

**class** `sympy.plotting.plot_implicit.ImplicitSeries(expr, var_start_end_x, var_start_end_y, has_equality, use_interval_math, depth, nb_of_points, line_color)`

Representation for Implicit plot

## Backends

**class** `sympy.plotting.plot.BaseBackend(parent)`

Base class for all backends. A backend represents the plotting library, which implements the necessary functionalities in order to use SymPy plotting functions.

How the plotting module works:

1. **Whenever a plotting function is called, the provided expressions are** processed and a list of instances of the [BaseSeries](#) (page 2865) class is created, containing the necessary information to plot the expressions (e.g. the expression, ranges, series name, ...). Eventually, these objects will generate the numerical data to be plotted.
2. **A [Plot](#) (page 2821) object is instantiated, which stores the list of** series and the main attributes of the plot (e.g. axis labels, title, ...).
3. **When the show command is executed, a new backend is instantiated,** which loops through each series object to generate and plot the numerical data. The backend is also going to set the axis labels, title, ..., according to the values stored in the Plot instance.

The backend should check if it supports the data series that it is given (e.g. [TextBackend](#) (page 2869) supports only [LineOver1DRangeSeries](#) (page 2866)).

It is the backend responsibility to know how to use the class of data series that it's given. Note that the current implementation of the \*Series classes is "matplotlib-centric": the numerical data returned by the `get_points` and `get_meshes` methods is meant to be used directly by Matplotlib. Therefore, the new backend will have to pre-process the numerical data to make it compatible with the chosen plotting library. Keep in mind that future SymPy versions may improve the \*Series classes in order to return numerical data "non-matplotlib-centric", hence if you code a new backend you have the responsibility to check if its working on each SymPy release.

Please explore the [MatplotlibBackend](#) (page 2868) source code to understand how a backend should be coded.

**See also:**

[MatplotlibBackend](#) (page 2868)

**class** `sympy.plotting.plot.MatplotlibBackend(parent)`

This class implements the functionalities to use Matplotlib with SymPy plotting functions.

**static** `get_segments(x, y, z=None)`

Convert two list of coordinates to a list of segments to be used with Matplotlib's [LineCollection](#).

**Parameters**

**x** : list

List of x-coordinates

**y**

[list] List of y-coordinates

**z**

[list] List of z-coordinates for a 3D line.

**process\_series()**

Iterates over every Plot object and further calls `_process_series()`

**class** `sympy.plotting.plot.TextBackend(parent)`

**Pyglet Plotting**

This is the documentation for the old plotting module that uses pyglet. This module has some limitations and is not actively developed anymore. For an alternative you can look at the new plotting module.

The pyglet plotting module can do nice 2D and 3D plots that can be controlled by console commands as well as keyboard and mouse, with the only dependency being [pyglet](#).

Here is the simplest usage:

```
>>> from sympy import var
>>> from sympy.plotting.pygletplot import PygletPlot as Plot
>>> var('x y z')
>>> Plot(x*y**3-y*x**3)
```

To see lots of plotting examples, see `examples/pyglet_plotting.py` and try running it in interactive mode (`python -i plotting.py`):

```
$ python -i examples/pyglet_plotting.py
```

And type for instance `example(7)` or `example(11)`.

See also the [Plotting Module](#) wiki page for screenshots.

**Plot Window Controls**

| Camera                 | Keys                                      |
|------------------------|-------------------------------------------|
| Sensitivity Modifier   | SHIFT                                     |

The mouse can be used to rotate, zoom, and translate by dragging the left, middle, and right mouse buttons respectively.

## Coordinate Modes

Plot supports several curvilinear coordinate modes, and they are independent for each plotted function. You can specify a coordinate mode explicitly with the 'mode' named argument, but it can be automatically determined for cartesian or parametric plots, and therefore must only be specified for polar, cylindrical, and spherical modes.

Specifically, `Plot(function arguments)` and `Plot.__setitem__(i, function arguments)` (accessed using array-index syntax on the Plot instance) will interpret your arguments as a cartesian plot if you provide one function and a parametric plot if you provide two or three functions. Similarly, the arguments will be interpreted as a curve if one variable is used, and a surface if two are used.

Supported mode names by number of variables:

- 1 (curves): parametric, cartesian, polar
- 2 (surfaces): parametric, cartesian, cylindrical, spherical

```
>>> Plot(1, 'mode=spherical; color=zfade4')
```

Note that function parameters are given as option strings of the form "key1=value1; key2 = value2" (spaces are truncated). Keyword arguments given directly to plot apply to the plot itself.

## Specifying Intervals for Variables

The basic format for variable intervals is [var, min, max, steps]. However, the syntax is quite flexible, and arguments not specified are taken from the defaults for the current coordinate mode:

```
>>> Plot(x**2) # implies [x, -5, 5, 100]
>>> Plot(x**2, [], []) # [x, -1, 1, 40], [y, -1, 1, 40]
>>> Plot(x**2-y**2, [100], [100]) # [x, -1, 1, 100], [y, -1, 1, 100]
>>> Plot(x**2, [x, -13, 13, 100])
>>> Plot(x**2, [-13, 13]) # [x, -13, 13, 100]
>>> Plot(x**2, [x, -13, 13]) # [x, -13, 13, 100]
>>> Plot(1*x, [], [x], 'mode=cylindrical') # [unbound_theta, 0, 2*Pi, 40], [x, -1,
↪ 1, 20]
```

## Using the Interactive Interface

```
>>> p = Plot(visible=False)
>>> f = x**2
>>> p[1] = f
>>> p[2] = f.diff(x)
>>> p[3] = f.diff(x).diff(x)
>>> p
[1]: x**2, 'mode=cartesian'
[2]: 2*x, 'mode=cartesian'
[3]: 2, 'mode=cartesian'
>>> p.show()
>>> p.clear()
>>> p
<blank plot>
>>> p[1] = x**2+y**2
>>> p[1].style = 'solid'
>>> p[2] = -x**2-y**2
>>> p[2].style = 'wireframe'
>>> p[1].color = z, (0.4,0.4,0.9), (0.9,0.4,0.4)
>>> p[1].style = 'both'
>>> p[2].style = 'both'
>>> p.close()
```

## Using Custom Color Functions

The following code plots a saddle and color it by the magnitude of its gradient:

```
>>> fz = x**2-y**2
>>> Fx, Fy, Fz = fz.diff(x), fz.diff(y), 0
>>> p[1] = fz, 'style=solid'
>>> p[1].color = (Fx**2 + Fy**2 + Fz**2)**(0.5)
```

The coloring algorithm works like this:

1. Evaluate the color function(s) across the curve or surface.
2. Find the minimum and maximum value of each component.
3. Scale each component to the color gradient.

When not specified explicitly, the default color gradient is  $f(0.0) = (0.4, 0.4, 0.4) \rightarrow f(1.0) = (0.9, 0.9, 0.9)$ . In our case, everything is gray-scale because we have applied the default color gradient uniformly for each color component. When defining a color scheme in this way, you might want to supply a color gradient as well:

```
>>> p[1].color = (Fx**2 + Fy**2 + Fz**2)**(0.5), (0.1,0.1,0.9), (0.9,0.1,0.1)
```

Here's a color gradient with four steps:

```
>>> gradient = [0.0, (0.1,0.1,0.9), 0.3, (0.1,0.9,0.1),
... 0.7, (0.9,0.9,0.1), 1.0, (1.0,0.0,0.0)]
>>> p[1].color = (Fx**2 + Fy**2 + Fz**2)**(0.5), gradient
```

The other way to specify a color scheme is to give a separate function for each component r, g, b. With this syntax, the default color scheme is defined:

```
>>> p[1].color = z,y,x, (0.4,0.4,0.4), (0.9,0.9,0.9)
```

This maps z->red, y->green, and x->blue. In some cases, you might prefer to use the following alternative syntax:

```
>>> p[1].color = z,(0.4,0.9), y,(0.4,0.9), x,(0.4,0.9)
```

You can still use multi-step gradients with three-function color schemes.

## Plotting Geometric Entities

The plotting module is capable of plotting some 2D geometric entities like line, circle and ellipse. The following example plots a circle centred at origin and of radius 2 units.

```
>>> from sympy import *
>>> x,y = symbols('x y')
>>> plot_implicit(Eq(x**2+y**2, 4))
```

Similarly, `plot_implicit()` (page 2847) may be used to plot any 2-D geometric structure from its implicit equation.

Plotting polygons (Polygon, RegularPolygon, Triangle) are not supported directly.

## Plotting with ASCII art

`sympy.plotting.textplot.textplot(expr, a, b, W=55, H=21)`

Print a crude ASCII art plot of the SymPy expression 'expr' (which should contain a single symbol, e.g. x or something else) over the interval [a, b].

### Examples

```
>>> from sympy import Symbol, sin
>>> from sympy.plotting import textplot
>>> t = Symbol('t')
>>> textplot(sin(t)*t, 0, 15)
```

(continues on next page)

(continued from previous page)

## Stats

SymPy statistics module

Introduces a random variable type into the SymPy language.

Random variables may be declared using prebuilt functions such as Normal, Exponential, Coin, Die, etc... or built with functions like FiniteRV.

Queries on random expressions can be made using the functions

| Expression                           | Meaning                      |
|--------------------------------------|------------------------------|
| $P(\text{condition})$                | Probability                  |
| $E(\text{expression})$               | Expected value               |
| $H(\text{expression})$               | Entropy                      |
| $\text{variance}(\text{expression})$ | Variance                     |
| $\text{density}(\text{expression})$  | Probability Density Function |
| $\text{sample}(\text{expression})$   | Produce a realization        |
| $\text{where}(\text{condition})$     | Where the condition is true  |

## Examples

```
>>> from sympy.stats import P, E, variance, Die, Normal
>>> from sympy import simplify
>>> X, Y = Die('X', 6), Die('Y', 6) # Define two six sided dice
>>> Z = Normal('Z', 0, 1) # Declare a Normal random variable with mean 0, std.
 ↪ 1
>>> P(X>3) # Probability X is greater than 3
1/2
>>> E(X+Y) # Expectation of the sum of two dice
7
>>> variance(X+Y) # Variance of the sum of two dice
35/6
>>> simplify(P(Z>1)) # Probability of Z being greater than 1
1/2 - erf(sqrt(2)/2)/2
```

One could also create custom distribution and define custom random variables as follows:

1. If you want to create a Continuous Random Variable:

```
>>> from sympy.stats import ContinuousRV, P, E
>>> from sympy import exp, Symbol, Interval, oo
>>> x = Symbol('x')
>>> pdf = exp(-x) # pdf of the Continuous Distribution
>>> Z = ContinuousRV(x, pdf, set=Interval(0, oo))
>>> E(Z)
1
>>> P(Z > 5)
exp(-5)
```

1.1 To create an instance of Continuous Distribution:

```
>>> from sympy.stats import ContinuousDistributionHandmade
>>> from sympy import Lambda
>>> dist = ContinuousDistributionHandmade(Lambda(x, pdf), set=Interval(0, oo))
>>> dist.pdf(x)
exp(-x)
```

2. If you want to create a Discrete Random Variable:

```
>>> from sympy.stats import DiscreteRV, P, E
>>> from sympy import Symbol, S
>>> p = S(1)/2
>>> x = Symbol('x', integer=True, positive=True)
>>> pdf = p*(1 - p)**(x - 1)
>>> D = DiscreteRV(x, pdf, set=S.Naturals)
>>> E(D)
2
>>> P(D > 3)
1/8
```

2.1 To create an instance of Discrete Distribution:

```
>>> from sympy.stats import DiscreteDistributionHandmade
>>> from sympy import Lambda
>>> dist = DiscreteDistributionHandmade(Lambda(x, pdf), set=S.Naturals)
>>> dist.pdf(x)
2**(1 - x)/2
```

3. If you want to create a Finite Random Variable:

```
>>> from sympy.stats import FiniteRV, P, E
>>> from sympy import Rational, Eq
>>> pmf = {1: Rational(1, 3), 2: Rational(1, 6), 3: Rational(1, 4), 4:
↳ Rational(1, 4)}
>>> X = FiniteRV('X', pmf)
>>> E(X)
29/12
>>> P(X > 3)
1/4
```

3.1 To create an instance of Finite Distribution:

```
>>> from sympy.stats import FiniteDistributionHandmade
>>> dist = FiniteDistributionHandmade(pmf)
>>> dist.pmf(x)
Lambda(x, Piecewise((1/3, Eq(x, 1)), (1/6, Eq(x, 2)), (1/4, Eq(x, 3) | Eq(x, 4)), (0, True)))
```

## Random Variable Types

### Finite Types

`sympy.stats.DiscreteUniform(name, items)`

Create a Finite Random Variable representing a uniform distribution over the input set.

#### Parameters

**items** : list/tuple

Items over which Uniform distribution is to be made

#### Returns

RandomSymbol

### Examples

```
>>> from sympy.stats import DiscreteUniform, density
>>> from sympy import symbols
```

```
>>> X = DiscreteUniform('X', symbols('a b c')) # equally likely over a, b, c
>>> density(X).dict
{a: 1/3, b: 1/3, c: 1/3}
```

```
>>> Y = DiscreteUniform('Y', list(range(5))) # distribution over a range
>>> density(Y).dict
{0: 1/5, 1: 1/5, 2: 1/5, 3: 1/5, 4: 1/5}
```

### References

[R803], [R804]

`sympy.stats.Die(name, sides=6)`

Create a Finite Random Variable representing a fair die.

#### Parameters

**sides** : Integer

Represents the number of sides of the Die, by default is 6

#### Returns

RandomSymbol

## Examples

```
>>> from sympy.stats import Die, density
>>> from sympy import Symbol
```

```
>>> D6 = Die('D6', 6) # Six sided Die
>>> density(D6).dict
{1: 1/6, 2: 1/6, 3: 1/6, 4: 1/6, 5: 1/6, 6: 1/6}
```

```
>>> D4 = Die('D4', 4) # Four sided Die
>>> density(D4).dict
{1: 1/4, 2: 1/4, 3: 1/4, 4: 1/4}
```

```
>>> n = Symbol('n', positive=True, integer=True)
>>> Dn = Die('Dn', n) # n sided Die
>>> density(Dn).dict
Density(DieDistribution(n))
>>> density(Dn).dict.subs(n, 4).doit()
{1: 1/4, 2: 1/4, 3: 1/4, 4: 1/4}
```

`sympy.stats.Bernoulli(name, p, succ=1, fail=0)`

Create a Finite Random Variable representing a Bernoulli process.

### Parameters

**p** : Rational number between 0 and 1

Represents probability of success

**succ** : Integer/symbol/string

Represents event of success

**fail** : Integer/symbol/string

Represents event of failure

### Returns

RandomSymbol

## Examples

```
>>> from sympy.stats import Bernoulli, density
>>> from sympy import S
```

```
>>> X = Bernoulli('X', S(3)/4) # 1-0 Bernoulli variable, probability = 3/
↪4
>>> density(X).dict
{0: 1/4, 1: 3/4}
```

```
>>> X = Bernoulli('X', S.Half, 'Heads', 'Tails') # A fair coin toss
>>> density(X).dict
{Heads: 1/2, Tails: 1/2}
```

## References

[R805], [R806]

`sympy.stats.Coin(name, p=1 / 2)`

Create a Finite Random Variable representing a Coin toss.

### Parameters

**p** : Rational Numeber between 0 and 1

Represents probability of getting “Heads”, by default is Half

### Returns

RandomSymbol

## Examples

```
>>> from sympy.stats import Coin, density
>>> from sympy import Rational
```

```
>>> C = Coin('C') # A fair coin toss
>>> density(C).dict
{H: 1/2, T: 1/2}
```

```
>>> C2 = Coin('C2', Rational(3, 5)) # An unfair coin
>>> density(C2).dict
{H: 3/5, T: 2/5}
```

### See also:

[`sympy.stats.Binomial`](#) (page 2877)

## References

[R807]

`sympy.stats.Binomial(name, n, p, succ=1, fail=0)`

Create a Finite Random Variable representing a binomial distribution.

### Parameters

**n** : Positive Integer

Represents number of trials

**p** : Rational Number between 0 and 1

Represents probability of success

**succ** : Integer/symbol/string

Represents event of success, by default is 1

**fail** : Integer/symbol/string

Represents event of failure, by default is 0

### Returns

RandomSymbol

## Examples

```
>>> from sympy.stats import Binomial, density
>>> from sympy import S, Symbol
```

```
>>> X = Binomial('X', 4, S.Half) # Four "coin flips"
>>> density(X).dict
{0: 1/16, 1: 1/4, 2: 3/8, 3: 1/4, 4: 1/16}
```

```
>>> n = Symbol('n', positive=True, integer=True)
>>> p = Symbol('p', positive=True)
>>> X = Binomial('X', n, S.Half) # n "coin flips"
>>> density(X).dict
Density(BinomialDistribution(n, 1/2, 1, 0))
>>> density(X).dict.subs(n, 4).doit()
{0: 1/16, 1: 1/4, 2: 3/8, 3: 1/4, 4: 1/16}
```

## References

[R808], [R809]

`sympy.stats.BetaBinomial(name, n, alpha, beta)`

Create a Finite Random Variable representing a Beta-binomial distribution.

### Parameters

**n** : Positive Integer

Represents number of trials

**alpha** : Real positive number

**beta** : Real positive number

### Returns

RandomSymbol

## Examples

```
>>> from sympy.stats import BetaBinomial, density
```

```
>>> X = BetaBinomial('X', 2, 1, 1)
>>> density(X).dict
{0: 1/3, 1: 2*beta(2, 2), 2: 1/3}
```

## References

[R810], [R811]

`sympy.stats.Hypergeometric(name, N, m, n)`

Create a Finite Random Variable representing a hypergeometric distribution.

### Parameters

**N** : Positive Integer

Represents finite population of size N.

**m** : Positive Integer

Represents number of trials with required feature.

**n** : Positive Integer

Represents numbers of draws.

### Returns

RandomSymbol

## Examples

```
>>> from sympy.stats import Hypergeometric, density
```

```
>>> X = Hypergeometric('X', 10, 5, 3) # 10 marbles, 5 white (success), 3
↳ draws
>>> density(X).dict
{0: 1/12, 1: 5/12, 2: 5/12, 3: 1/12}
```

## References

[R812], [R813]

`sympy.stats.FiniteRV(name, density, **kwargs)`

Create a Finite Random Variable given a dict representing the density.

### Parameters

**name** : Symbol

Represents name of the random variable.

**density** : dict

Dictionary containing the pdf of finite distribution

**check** : bool

If True, it will check whether the given density integrates to 1 over the given set. If False, it will not perform this check. Default is False.

### Returns

RandomSymbol

### Examples

```
>>> from sympy.stats import FiniteRV, P, E
```

```
>>> density = {0: .1, 1: .2, 2: .3, 3: .4}
>>> X = FiniteRV('X', density)
```

```
>>> E(X)
2.0000000000000000
>>> P(X >= 2)
0.7000000000000000
```

`sympy.stats.Rademacher(name)`

Create a Finite Random Variable representing a Rademacher distribution.

#### Returns

RandomSymbol

### Examples

```
>>> from sympy.stats import Rademacher, density
```

```
>>> X = Rademacher('X')
>>> density(X).dict
{-1: 1/2, 1: 1/2}
```

#### See also:

[`sympy.stats.Bernoulli`](#) (page 2876)

### References

[R814]

## Discrete Types

`sympy.stats.Geometric(name, p)`

Create a discrete random variable with a Geometric distribution.

#### Parameters

**p** : A probability between 0 and 1

#### Returns

RandomSymbol

## Explanation

The density of the Geometric distribution is given by

$$f(k) := p(1 - p)^{k-1}$$

## Examples

```
>>> from sympy.stats import Geometric, density, E, variance
>>> from sympy import Symbol, S
```

```
>>> p = S.One / 5
>>> z = Symbol("z")
```

```
>>> X = Geometric("x", p)
```

```
>>> density(X)(z)
(4/5)**(z - 1)/5
```

```
>>> E(X)
5
```

```
>>> variance(X)
20
```

## References

[R815], [R816]

`sympy.stats.Hermite(name, a1, a2)`

Create a discrete random variable with a Hermite distribution.

### Parameters

**a1** : A Positive number greater than equal to 0.

**a2** : A Positive number greater than equal to 0.

### Returns

RandomSymbol

## Explanation

The density of the Hermite distribution is given by

$$f(x) := e^{-a_1 - a_2} \sum_{j=0}^{\lfloor x/2 \rfloor} \frac{a_1^{x-2j} a_2^j}{(x-2j)! j!}$$

## Examples

```
>>> from sympy.stats import Hermite, density, E, variance
>>> from sympy import Symbol
```

```
>>> a1 = Symbol("a1", positive=True)
>>> a2 = Symbol("a2", positive=True)
>>> x = Symbol("x")
```

```
>>> H = Hermite("H", a1=5, a2=4)
```

```
>>> density(H)(2)
33*exp(-9)/2
```

```
>>> E(H)
13
```

```
>>> variance(H)
21
```

## References

[R817]

`sympy.stats.Poisson(name, lamda)`

Create a discrete random variable with a Poisson distribution.

### Parameters

**lamda** : Positive number, a rate

### Returns

RandomSymbol

## Explanation

The density of the Poisson distribution is given by

$$f(k) := \frac{\lambda^k e^{-\lambda}}{k!}$$

## Examples

```
>>> from sympy.stats import Poisson, density, E, variance
>>> from sympy import Symbol, simplify
```

```
>>> rate = Symbol("lambda", positive=True)
>>> z = Symbol("z")
```

```
>>> X = Poisson("x", rate)
```

```
>>> density(X)(z)
lambda**z*exp(-lambda)/factorial(z)
```

```
>>> E(X)
lambda
```

```
>>> simplify(variance(X))
lambda
```

## References

[R818], [R819]

`sympy.stats.Logarithmic(name, p)`

Create a discrete random variable with a Logarithmic distribution.

### Parameters

**p** : A value between 0 and 1

### Returns

RandomSymbol

## Explanation

The density of the Logarithmic distribution is given by

$$f(k) := \frac{-p^k}{k \ln(1-p)}$$

## Examples

```
>>> from sympy.stats import Logarithmic, density, E, variance
>>> from sympy import Symbol, S
```

```
>>> p = S.One / 5
>>> z = Symbol("z")
```

```
>>> X = Logarithmic("x", p)
```

```
>>> density(X)(z)
-1/(5**z*z*log(4/5))
```

```
>>> E(X)
-1/(-4*log(5) + 8*log(2))
```

```
>>> variance(X)
-1/((-4*log(5) + 8*log(2))*(-2*log(5) + 4*log(2))) + 1/(-
→ 64*log(2)*log(5) + 64*log(2)**2 + 16*log(5)**2) - 10/(-32*log(5) +
→ 64*log(2))
```

## References

[R820], [R821]

`sympy.stats.NegativeBinomial(name, r, p)`

Create a discrete random variable with a Negative Binomial distribution.

### Parameters

**r** : A positive value

**p** : A value between 0 and 1

### Returns

RandomSymbol

## Explanation

The density of the Negative Binomial distribution is given by

$$f(k) := \binom{k+r-1}{k} (1-p)^r p^k$$

## Examples

```
>>> from sympy.stats import NegativeBinomial, density, E, variance
>>> from sympy import Symbol, S
```

```
>>> r = 5
>>> p = S.One / 5
>>> z = Symbol("z")
```

```
>>> X = NegativeBinomial("x", r, p)
```

```
>>> density(X)(z)
1024*binomial(z + 4, z)/(3125*5**z)
```

```
>>> E(X)
5/4
```

```
>>> variance(X)
25/16
```

## References

[R822], [R823]

`sympy.stats.Skellam(name, mu1, mu2)`

Create a discrete random variable with a Skellam distribution.

### Parameters

**mu1** : A non-negative value

**mu2** : A non-negative value

### Returns

RandomSymbol

## Explanation

The Skellam is the distribution of the difference  $N1 - N2$  of two statistically independent random variables  $N1$  and  $N2$  each Poisson-distributed with respective expected values  $\mu1$  and  $\mu2$ .

The density of the Skellam distribution is given by

$$f(k) := e^{-(\mu_1 + \mu_2)} \left( \frac{\mu_1}{\mu_2} \right)^{k/2} I_k(2\sqrt{\mu_1 \mu_2})$$

## Examples

```
>>> from sympy.stats import Skellam, density, E, variance
>>> from sympy import Symbol, pprint
```

```
>>> z = Symbol("z", integer=True)
>>> mu1 = Symbol("mu1", positive=True)
>>> mu2 = Symbol("mu2", positive=True)
>>> X = Skellam("x", mu1, mu2)
```

```
>>> pprint(density(X)(z), use_unicode=False)
 z
 -
 2
/mu1\ -mu1 - mu2 /
|---| *e *besseli\z, 2*\ / mu1 * \ / mu2 /
\mu2/
>>> E(X)
mu1 - mu2
>>> variance(X).expand()
mu1 + mu2
```

## References

[R824]

`sympy.stats.YuleSimon(name, rho)`

Create a discrete random variable with a Yule-Simon distribution.

### Parameters

**rho** : A positive value

### Returns

RandomSymbol

## Explanation

The density of the Yule-Simon distribution is given by

$$f(k) := \rho B(k, \rho + 1)$$

## Examples

```
>>> from sympy.stats import YuleSimon, density, E, variance
>>> from sympy import Symbol, simplify
```

```
>>> p = 5
>>> z = Symbol("z")
```

```
>>> X = YuleSimon("x", p)
```

```
>>> density(X)(z)
5*beta(z, 6)
```

```
>>> simplify(E(X))
5/4
```

```
>>> simplify(variance(X))
25/48
```

## References

[R825]

`sympy.stats.Zeta(name, s)`

Create a discrete random variable with a Zeta distribution.

### Parameters

**s** : A value greater than 1

### Returns

RandomSymbol

## Explanation

The density of the Zeta distribution is given by

$$f(k) := \frac{1}{k^s \zeta(s)}$$

## Examples

```
>>> from sympy.stats import Zeta, density, E, variance
>>> from sympy import Symbol
```

```
>>> s = 5
>>> z = Symbol("z")
```

```
>>> X = Zeta("x", s)
```

```
>>> density(X)(z)
1/(z**5*zeta(5))
```

```
>>> E(X)
pi**4/(90*zeta(5))
```

```
>>> variance(X)
-pi**8/(8100*zeta(5)**2) + zeta(3)/zeta(5)
```

## References

[R826]

## Continuous Types

`sympy.stats.Arcsin(name, a=0, b=1)`

Create a Continuous Random Variable with an arcsin distribution.

The density of the arcsin distribution is given by

$$f(x) := \frac{1}{\pi \sqrt{(x-a)(b-x)}}$$

with  $x \in (a, b)$ . It must hold that  $-\infty < a < b < \infty$ .

### Parameters

**a** : Real number, the left interval boundary

**b** : Real number, the right interval boundary

### Returns

RandomSymbol

## Examples

```
>>> from sympy.stats import Arcsin, density, cdf
>>> from sympy import Symbol
```

```
>>> a = Symbol("a", real=True)
>>> b = Symbol("b", real=True)
>>> z = Symbol("z")
```

```
>>> X = Arcsin("x", a, b)
```

```
>>> density(X)(z)
1/(pi*sqrt((-a + z)*(b - z)))
```

```
>>> cdf(X)(z)
Piecewise((0, a > z),
 (2*asin(sqrt((-a + z)/(-a + b)))/pi, b >= z),
 (1, True))
```

## References

[R827]

`sympy.stats.Benini(name, alpha, beta, sigma)`

Create a Continuous Random Variable with a Benini distribution.

The density of the Benini distribution is given by

$$f(x) := e^{-\alpha \log \frac{x}{\sigma} - \beta \log^2 \left[ \frac{x}{\sigma} \right]} \left( \frac{\alpha}{x} + \frac{2\beta \log \frac{x}{\sigma}}{x} \right)$$

This is a heavy-tailed distribution and is also known as the log-Rayleigh distribution.

### Parameters

**alpha** : Real number,  $\alpha > 0$ , a shape

**beta** : Real number,  $\beta > 0$ , a shape

**sigma** : Real number,  $\sigma > 0$ , a scale

### Returns

RandomSymbol

## Examples

```
>>> from sympy.stats import Benini, density, cdf
>>> from sympy import Symbol, pprint
```

```
>>> alpha = Symbol("alpha", positive=True)
>>> beta = Symbol("beta", positive=True)
>>> sigma = Symbol("sigma", positive=True)
>>> z = Symbol("z")
```

```
>>> X = Benini("x", alpha, beta, sigma)
```

```
>>> D = density(X)(z)
>>> pprint(D, use_unicode=False)
/
| 2*beta*log|-----| - alpha*log|-----| - beta*log 2/ z \
|alpha \|sigma/ \|sigma/ \|sigma/
|----- + -----|*e
\ z z /
```

```
>>> cdf(X)(z)
Piecewise((1 - exp(-alpha*log(z/sigma) - beta*log(z/sigma)**2), sigma <=
→ z),
 (0, True))
```

## References

`sympy.stats.Beta(name, alpha, beta)`

Create a Continuous Random Variable with a Beta distribution.

The density of the Beta distribution is given by

$$f(x) := \frac{x^{\alpha-1}(1-x)^{\beta-1}}{B(\alpha, \beta)}$$

with  $x \in [0, 1]$ .

### Parameters

**alpha** : Real number,  $\alpha > 0$ , a shape

**beta** : Real number,  $\beta > 0$ , a shape

### Returns

RandomSymbol

## Examples

```
>>> from sympy.stats import Beta, density, E, variance
>>> from sympy import Symbol, simplify, pprint, factor
```

```
>>> alpha = Symbol("alpha", positive=True)
>>> beta = Symbol("beta", positive=True)
>>> z = Symbol("z")
```

```
>>> X = Beta("x", alpha, beta)
```

```
>>> D = density(X)(z)
>>> pprint(D, use_unicode=False)
alpha - 1 beta - 1
```

(continues on next page)

(continued from previous page)

$$\frac{z^{alpha-1} (1-z)^{beta-1}}{B(alpha, beta)}$$

```
>>> simplify(E(X))
alpha/(alpha + beta)
```

```
>>> factor(simplify(variance(X)))
alpha*beta/((alpha + beta)**2*(alpha + beta + 1))
```

## References

[R830], [R831]

`sympy.stats.BetaNoncentral`(*name, alpha, beta, lamda*)

Create a Continuous Random Variable with a Type I Noncentral Beta distribution.

The density of the Noncentral Beta distribution is given by

$$f(x) := \sum_{k=0}^{\infty} e^{-\lambda/2} \frac{(\lambda/2)^k}{k!} \frac{x^{\alpha+k-1} (1-x)^{\beta-1}}{B(\alpha+k, \beta)}$$

with  $x \in [0, 1]$ .

### Parameters

**alpha** : Real number,  $\alpha > 0$ , a shape

**beta** : Real number,  $\beta > 0$ , a shape

**lamda** : Real number,  $\lambda \geq 0$ , noncentrality parameter

### Returns

RandomSymbol

## Examples

```
>>> from sympy.stats import BetaNoncentral, density, cdf
>>> from sympy import Symbol, pprint
```

```
>>> alpha = Symbol("alpha", positive=True)
>>> beta = Symbol("beta", positive=True)
>>> lamda = Symbol("lamda", nonnegative=True)
>>> z = Symbol("z")
```

```
>>> X = BetaNoncentral("x", alpha, beta, lamda)
```

```
>>> D = density(X)(z)
>>> pprint(D, use_unicode=False)
oo
```

(continues on next page)

(continued from previous page)

$$\frac{z^{k+\alpha-1} \lambda^{\alpha-1} \Gamma(\alpha) \Gamma(\beta)}{\Gamma(\alpha+\beta)} \frac{\lambda^k}{2^k} (1-z)^{\beta-1} e^{-\lambda z} = \frac{B(k+\alpha, \beta) k!}{B(k+\alpha, \beta) k!}$$

$k = 0$

Compute cdf with specific 'x', 'alpha', 'beta' and 'lamda' values as follows:

```
>>> cdf(BetaNoncentral("x", 1, 1, 1), evaluate=False)(2).doit()
2*exp(1/2)
```

The argument `evaluate=False` prevents an attempt at evaluation of the sum for general `x`, before the argument `2` is passed.

## References

[R832], [R833]

`sympy.stats.BetaPrime(name, alpha, beta)`

Create a continuous random variable with a Beta prime distribution.

The density of the Beta prime distribution is given by

$$f(x) := \frac{x^{\alpha-1} (1+x)^{-\alpha-\beta}}{B(\alpha, \beta)}$$

with  $x > 0$ .

### Parameters

**alpha** : Real number,  $\alpha > 0$ , a shape

**beta** : Real number,  $\beta > 0$ , a shape

### Returns

RandomSymbol

## Examples

```
>>> from sympy.stats import BetaPrime, density
>>> from sympy import Symbol, pprint
```

```
>>> alpha = Symbol("alpha", positive=True)
>>> beta = Symbol("beta", positive=True)
>>> z = Symbol("z")
```

```
>>> X = BetaPrime("x", alpha, beta)
```

```
>>> D = density(X)(z)
>>> pprint(D, use_unicode=False)
 alpha - 1 -alpha - beta
 z *(z + 1)

 B(alpha, beta)
```

## References

[R834], [R835]

`sympy.stats.BoundedPareto`(*name*, *alpha*, *left*, *right*)

Create a continuous random variable with a Bounded Pareto distribution.

The density of the Bounded Pareto distribution is given by

$$f(x) := \frac{\alpha L^\alpha x^{-\alpha-1}}{1 - (\frac{L}{H})^\alpha}$$

### Parameters

**alpha** : Real Number,  $\alpha > 0$

Shape parameter

**left** : Real Number,  $left > 0$

Location parameter

**right** : Real Number,  $right > left$

Location parameter

### Returns

RandomSymbol

## Examples

```
>>> from sympy.stats import BoundedPareto, density, cdf, E
>>> from sympy import symbols
>>> L, H = symbols('L, H', positive=True)
>>> X = BoundedPareto('X', 2, L, H)
>>> x = symbols('x')
>>> density(X)(x)
2*L**2/(x**3*(1 - L**2/H**2))
>>> cdf(X)(x)
Piecewise((-H**2*L**2/(x**2*(H**2 - L**2)) + H**2/(H**2 - L**2), L <= x),
 (0, True))
>>> E(X).simplify()
2*H*L/(H + L)
```

## References

[R836]

`sympy.stats.Cauchy(name, x0, gamma)`

Create a continuous random variable with a Cauchy distribution.

The density of the Cauchy distribution is given by

$$f(x) := \frac{1}{\pi\gamma[1 + (\frac{x-x_0}{\gamma})^2]}$$

### Parameters

**x0** : Real number, the location

**gamma** : Real number,  $\gamma > 0$ , a scale

### Returns

RandomSymbol

## Examples

```
>>> from sympy.stats import Cauchy, density
>>> from sympy import Symbol
```

```
>>> x0 = Symbol("x0")
>>> gamma = Symbol("gamma", positive=True)
>>> z = Symbol("z")
```

```
>>> X = Cauchy("x", x0, gamma)
```

```
>>> density(X)(z)
1/(pi*gamma*(1 + (-x0 + z)**2/gamma**2))
```

## References

[R837], [R838]

`sympy.stats.Chi(name, k)`

Create a continuous random variable with a Chi distribution.

The density of the Chi distribution is given by

$$f(x) := \frac{2^{1-k/2} x^{k-1} e^{-x^2/2}}{\Gamma(k/2)}$$

with  $x \geq 0$ .

### Parameters

**k** : Positive integer, The number of degrees of freedom

### Returns

RandomSymbol

## Examples

```
>>> from sympy.stats import Chi, density, E
>>> from sympy import Symbol, simplify
```

```
>>> k = Symbol("k", integer=True)
>>> z = Symbol("z")
```

```
>>> X = Chi("x", k)
```

```
>>> density(X)(z)
2**(1 - k/2)*z**(k - 1)*exp(-z**2/2)/gamma(k/2)
```

```
>>> simplify(E(X))
sqrt(2)*gamma(k/2 + 1/2)/gamma(k/2)
```

## References

[R839], [R840]

`sympy.stats.ChiNoncentral`(*name*, *k*, *l*)

Create a continuous random variable with a non-central Chi distribution.

### Parameters

**k** : A positive Integer,  $k > 0$

The number of degrees of freedom.

**lambda** : Real number,  $\lambda > 0$

Shift parameter.

### Returns

RandomSymbol

## Explanation

The density of the non-central Chi distribution is given by

$$f(x) := \frac{e^{-(x^2+\lambda^2)/2} x^k \lambda}{(\lambda x)^{k/2}} I_{k/2-1}(\lambda x)$$

with  $x \geq 0$ . Here,  $I_\nu(x)$  is the *modified Bessel function of the first kind* (page 499).

## Examples

```
>>> from sympy.stats import ChiNoncentral, density
>>> from sympy import Symbol
```

```
>>> k = Symbol("k", integer=True)
>>> l = Symbol("l")
>>> z = Symbol("z")
```

```
>>> X = ChiNoncentral("x", k, l)
```

```
>>> density(X)(z)
l*z**k*exp(-l**2/2 - z**2/2)*besseli(k/2 - 1, l*z)/(l*z)**(k/2)
```

## References

[R841]

`sympy.stats.ChiSquared(name, k)`

Create a continuous random variable with a Chi-squared distribution.

### Parameters

**k** : Positive integer

The number of degrees of freedom.

### Returns

RandomSymbol

## Explanation

The density of the Chi-squared distribution is given by

$$f(x) := \frac{1}{2^{\frac{k}{2}} \Gamma(\frac{k}{2})} x^{\frac{k}{2}-1} e^{-\frac{x}{2}}$$

with  $x \geq 0$ .

## Examples

```
>>> from sympy.stats import ChiSquared, density, E, variance, moment
>>> from sympy import Symbol
```

```
>>> k = Symbol("k", integer=True, positive=True)
>>> z = Symbol("z")
```

```
>>> X = ChiSquared("x", k)
```

```
>>> density(X)(z)
z**(k/2 - 1)*exp(-z/2)/(2**(k/2)*gamma(k/2))
```

```
>>> E(X)
k
```

```
>>> variance(X)
2*k
```

```
>>> moment(X, 3)
k**3 + 6*k**2 + 8*k
```

## References

[R842], [R843]

`sympy.stats.Dagum(name, p, a, b)`

Create a continuous random variable with a Dagum distribution.

### Parameters

**p** : Real number

$p > 0$ , a shape.

**a** : Real number

$a > 0$ , a shape.

**b** : Real number

$b > 0$ , a scale.

### Returns

RandomSymbol

## Explanation

The density of the Dagum distribution is given by

$$f(x) := \frac{ap}{x} \left( \frac{\left(\frac{x}{b}\right)^{ap}}{\left(\left(\frac{x}{b}\right)^a + 1\right)^{p+1}} \right)$$

with  $x > 0$ .

## Examples

```
>>> from sympy.stats import Dagum, density, cdf
>>> from sympy import Symbol
```

```
>>> p = Symbol("p", positive=True)
>>> a = Symbol("a", positive=True)
>>> b = Symbol("b", positive=True)
>>> z = Symbol("z")
```

```
>>> X = Dagum("x", p, a, b)
```

```
>>> density(X)(z)
a*p*(z/b)**(a*p)*((z/b)**a + 1)**(-p - 1)/z
```

```
>>> cdf(X)(z)
Piecewise(((1 + (z/b)**(-a))**(-p), z >= 0), (0, True))
```

## References

[R844]

`sympy.stats.Erlang(name, k, l)`

Create a continuous random variable with an Erlang distribution.

### Parameters

**k** : Positive integer

**l** : Real number,  $\lambda > 0$ , the rate

### Returns

RandomSymbol

## Explanation

The density of the Erlang distribution is given by

$$f(x) := \frac{\lambda^k x^{k-1} e^{-\lambda x}}{(k-1)!}$$

with  $x \in [0, \infty]$ .

## Examples

```
>>> from sympy.stats import Erlang, density, cdf, E, variance
>>> from sympy import Symbol, simplify, pprint
```

```
>>> k = Symbol("k", integer=True, positive=True)
>>> l = Symbol("l", positive=True)
>>> z = Symbol("z")
```

```
>>> X = Erlang("x", k, l)
```

```
>>> D = density(X)(z)
>>> pprint(D, use_unicode=False)
 k k - 1 -l*z
l *z *e

 Gamma(k)
```

```
>>> C = cdf(X)(z)
>>> pprint(C, use_unicode=False)
/lowergamma(k, l*z)
|----- for z > 0
| Gamma(k)
|
| 0 otherwise
\
```

```
>>> E(X)
k/l
```

```
>>> simplify(variance(X))
k/l**2
```

## References

[R845], [R846]

`sympy.stats.ExGaussian(name, mean, std, rate)`

Create a continuous random variable with an Exponentially modified Gaussian (EMG) distribution.

### Parameters

**name** : A string giving a name for this distribution

**mean** : A Real number, the mean of Gaussian component

**std** : A positive Real number,

**math**

$\sigma^2 > 0$  the variance of Gaussian component

**rate** : A positive Real number,

**math**

$\lambda > 0$  the rate of Exponential component

### Returns

RandomSymbol

## Explanation

The density of the exponentially modified Gaussian distribution is given by

$$f(x) := \frac{\lambda}{2} e^{\frac{\lambda}{2}(2\mu + \lambda\sigma^2 - 2x)} \operatorname{erfc}\left(\frac{\mu + \lambda\sigma^2 - x}{\sqrt{2}\sigma}\right)$$

with  $x > 0$ . Note that the expected value is  $1/\lambda$ .

## Examples

```
>>> from sympy.stats import ExGaussian, density, cdf, E
>>> from sympy.stats import variance, skewness
>>> from sympy import Symbol, pprint, simplify
```

```
>>> mean = Symbol("mu")
>>> std = Symbol("sigma", positive=True)
>>> rate = Symbol("lamda", positive=True)
>>> z = Symbol("z")
>>> X = ExGaussian("x", mean, std, rate)
```

```
>>> pprint(density(X)(z), use_unicode=False)
 / 2 \
lamda*\lamda*sigma + 2*mu - 2*z/
----- / ____ / 2
-> \\\
 2 |\ / 2 *\lamda*sigma + mu -
-> z/|
lamda*e *erfc|-----
-> --|
 \ 2*sigma
-> /

-> ---
 2
```

```
>>> cdf(X)(z)
-(erf(sqrt(2)*(-lamda**2*sigma**2 + lamda*(-mu + z))/(2*lamda*sigma))/2
-> + 1/2)*exp(lamda**2*sigma**2/2 - lamda*(-mu + z)) + erf(sqrt(2)*(-mu +
-> z)/(2*sigma))/2 + 1/2
```

```
>>> E(X)
(lamda*mu + 1)/lamda
```

```
>>> simplify(variance(X))
sigma**2 + lamda**(-2)
```

```
>>> simplify(skewness(X))
2/(lamda**2*sigma**2 + 1)**(3/2)
```

## References

[R847]

`sympy.stats.Exponential(name, rate)`

Create a continuous random variable with an Exponential distribution.

### Parameters

**rate** : A positive Real number,  $\lambda > 0$ , the rate (or inverse scale/inverse mean)

### Returns

RandomSymbol

## Explanation

The density of the exponential distribution is given by

$$f(x) := \lambda \exp(-\lambda x)$$

with  $x > 0$ . Note that the expected value is  $1/\lambda$ .

## Examples

```
>>> from sympy.stats import Exponential, density, cdf, E
>>> from sympy.stats import variance, std, skewness, quantile
>>> from sympy import Symbol
```

```
>>> l = Symbol("lambda", positive=True)
>>> z = Symbol("z")
>>> p = Symbol("p")
>>> X = Exponential("x", l)
```

```
>>> density(X)(z)
lambda*exp(-lambda*z)
```

```
>>> cdf(X)(z)
Piecewise((1 - exp(-lambda*z), z >= 0), (0, True))
```

```
>>> quantile(X)(p)
-log(1 - p)/lambda
```

```
>>> E(X)
1/lambda
```

```
>>> variance(X)
lambda**(-2)
```

```
>>> skewness(X)
2
```

```
>>> X = Exponential('x', 10)
```

```
>>> density(X)(z)
10*exp(-10*z)
```

```
>>> E(X)
1/10
```

```
>>> std(X)
1/10
```

## References

`sympy.stats.FDistribution(name, d1, d2)`

Create a continuous random variable with a F distribution.

### Parameters

**d1** :  $d_1 > 0$ , where  $d_1$  is the degrees of freedom ( $n_1 - 1$ )

**d2** :  $d_2 > 0$ , where  $d_2$  is the degrees of freedom ( $n_2 - 1$ )

### Returns

RandomSymbol

## Explanation

The density of the F distribution is given by

$$f(x) := \frac{\sqrt{\frac{(d_1 x)^{d_1} d_2^{d_2}}{(d_1 x + d_2)^{d_1 + d_2}}}}{x B\left(\frac{d_1}{2}, \frac{d_2}{2}\right)}$$

with  $x > 0$ .

## Examples

```
>>> from sympy.stats import FDistribution, density
>>> from sympy import Symbol, pprint
```

```
>>> d1 = Symbol("d1", positive=True)
>>> d2 = Symbol("d2", positive=True)
>>> z = Symbol("z")
```

```
>>> X = FDistribution("x", d1, d2)
```

```
>>> D = density(X)(z)
>>> pprint(D, use_unicode=False)
d2
--
2 / d1 -d1 - d2

`sympy.stats.FisherZ(name, d1, d2)`

Create a Continuous Random Variable with an Fisher's Z distribution.

### Parameters

**d1** :  $d_1 > 0$

Degree of freedom.

**d2** :  $d_2 > 0$

Degree of freedom.

### Returns

RandomSymbol

## Explanation

The density of the Fisher's Z distribution is given by

$$f(x) := \frac{2d_1^{d_1/2} d_2^{d_2/2}}{B(d_1/2, d_2/2)} \frac{e^{d_1 z}}{(d_1 e^{2z} + d_2)^{(d_1+d_2)/2}}$$

## Examples

```
>>> from sympy.stats import FisherZ, density
>>> from sympy import Symbol, pprint
```

```
>>> d1 = Symbol("d1", positive=True)
>>> d2 = Symbol("d2", positive=True)
>>> z = Symbol("z")
```

```
>>> X = FisherZ("x", d1, d2)
```

```
>>> D = density(X)(z)
>>> pprint(D, use_unicode=False)

## References

[R852], [R853]

`sympy.stats.Frechet(name, a, s=1, m=0)`

Create a continuous random variable with a Frechet distribution.

### Parameters

**a** : Real number,  $a \in (0, \infty)$  the shape

**s** : Real number,  $s \in (0, \infty)$  the scale

**m** : Real number,  $m \in (-\infty, \infty)$  the minimum

### Returns

RandomSymbol

## Explanation

The density of the Frechet distribution is given by

$$f(x) := \frac{\alpha}{s} \left( \frac{x-m}{s} \right)^{-1-\alpha} e^{-\left( \frac{x-m}{s} \right)^{-\alpha}}$$

with  $x \geq m$ .

## Examples

```
>>> from sympy.stats import Frechet, density, cdf
>>> from sympy import Symbol
```

```
>>> a = Symbol("a", positive=True)
>>> s = Symbol("s", positive=True)
>>> m = Symbol("m", real=True)
>>> z = Symbol("z")
```

```
>>> X = Frechet("x", a, s, m)
```

```
>>> density(X)(z)
a*((-m + z)/s)**(-a - 1)*exp(-1/((-m + z)/s)**a)/s
```

```
>>> cdf(X)(z)
Piecewise((exp(-1/((-m + z)/s)**a), m <= z), (0, True))
```

`sympy.stats.Gamma(name, k, theta)`

Create a continuous random variable with a Gamma distribution.

### Parameters

**k** : Real number,  $k > 0$ , a shape

**theta** : Real number,  $\theta > 0$ , a scale

### Returns

RandomSymbol

## Explanation

The density of the Gamma distribution is given by

$$f(x) := \frac{1}{\Gamma(k)\theta^k} x^{k-1} e^{-\frac{x}{\theta}}$$

with  $x \in [0, 1]$ .

## Examples

```
>>> from sympy.stats import Gamma, density, cdf, E, variance
>>> from sympy import Symbol, pprint, simplify
```

```
>>> k = Symbol("k", positive=True)
>>> theta = Symbol("theta", positive=True)
>>> z = Symbol("z")
```

```
>>> X = Gamma("x", k, theta)
```

```
>>> D = density(X)(z)
>>> pprint(D, use_unicode=False)
 -z

 -k k - 1 theta
 theta *z *e

 Gamma(k)
```

```
>>> C = cdf(X, meijerg=True)(z)
>>> pprint(C, use_unicode=False)
/
| k*lowergamma|k, ----|
| \ theta/
<----- for z >= 0
| Gamma(k + 1)

`sympy.stats.GammaInverse(name, a, b)`

Create a continuous random variable with an inverse Gamma distribution.

### Parameters

**a** : Real number,  $a > 0$ , a shape

**b** : Real number,  $b > 0$ , a scale

### Returns

RandomSymbol

## Explanation

The density of the inverse Gamma distribution is given by

$$f(x) := \frac{\beta^\alpha}{\Gamma(\alpha)} x^{-\alpha-1} \exp\left(\frac{-\beta}{x}\right)$$

with  $x > 0$ .

## Examples

```
>>> from sympy.stats import GammaInverse, density, cdf
>>> from sympy import Symbol, pprint
```

```
>>> a = Symbol("a", positive=True)
>>> b = Symbol("b", positive=True)
>>> z = Symbol("z")
```

```
>>> X = GammaInverse("x", a, b)
```

```
>>> D = density(X)(z)
>>> pprint(D, use_unicode=False)
 -b

 a -a - 1 z
b *z *e

 Gamma(a)
```

```
>>> cdf(X)(z)
Piecewise((uppergamma(a, b/z)/gamma(a), z > 0), (0, True))
```

[R857]

`sympy.stats.Gompertz(name, b, eta)`

Create a Continuous Random Variable with Gompertz distribution.

### Parameters

**b** : Real number,  $b > 0$ , a scale

**eta** : Real number,  $\eta > 0$ , a shape

### Returns

RandomSymbol

## Explanation

The density of the Gompertz distribution is given by

$$f(x) := b\eta e^{bx} e^{\eta} \exp(-\eta e^{bx})$$

with  $x \in [0, \infty)$ .

## Examples

```
>>> from sympy.stats import Gompertz, density
>>> from sympy import Symbol
```

```
>>> b = Symbol("b", positive=True)
>>> eta = Symbol("eta", positive=True)
>>> z = Symbol("z")
```

```
>>> X = Gompertz("x", b, eta)
```

```
>>> density(X)(z)
b*eta*exp(eta)*exp(b*z)*exp(-eta*exp(b*z))
```

## References

[R858]

`sympy.stats.Gumbel(name, beta, mu, minimum=False)`

Create a Continuous Random Variable with Gumbel distribution.

### Parameters

**mu** : Real number,  $\mu$ , a location

**beta** : Real number,  $\beta > 0$ , a scale

**minimum** : Boolean, by default False, set to True for enabling minimum distribution

### Returns

RandomSymbol

## Explanation

The density of the Gumbel distribution is given by

For Maximum

$$f(x) := \frac{1}{\beta} \exp\left(-\frac{x-\mu}{\beta} - \exp\left(-\frac{x-\mu}{\beta}\right)\right)$$

with  $x \in [-\infty, \infty]$ .

For Minimum

$$f(x) := \frac{e^{-e^{-\frac{-\mu+x}{\beta}} + \frac{-\mu+x}{\beta}}}{\beta}$$

with  $x \in [-\infty, \infty]$ .

## Examples

```
>>> from sympy.stats import Gumbel, density, cdf
>>> from sympy import Symbol
>>> x = Symbol("x")
>>> mu = Symbol("mu")
>>> beta = Symbol("beta", positive=True)
>>> X = Gumbel("x", beta, mu)
>>> density(X)(x)
exp(-exp(-(-mu + x)/beta) - (-mu + x)/beta)/beta
>>> cdf(X)(x)
exp(-exp(-(-mu + x)/beta))
```

`sympy.stats.Kumaraswamy(name, a, b)`

Create a Continuous Random Variable with a Kumaraswamy distribution.

### Parameters

**a** : Real number,  $a > 0$ , a shape

**b** : Real number,  $b > 0$ , a shape

### Returns

RandomSymbol

## Explanation

The density of the Kumaraswamy distribution is given by

$$f(x) := abx^{a-1}(1-x^a)^{b-1}$$

with  $x \in [0, 1]$ .

## Examples

```
>>> from sympy.stats import Kumaraswamy, density, cdf
>>> from sympy import Symbol, pprint
```

```
>>> a = Symbol("a", positive=True)
>>> b = Symbol("b", positive=True)
>>> z = Symbol("z")
```

```
>>> X = Kumaraswamy("x", a, b)
```

```
>>> D = density(X)(z)
>>> pprint(D, use_unicode=False)
 b - 1
 a - 1 / a\
a*b*z *\1 - z /
```

```
>>> cdf(X)(z)
Piecewise((0, z < 0), (1 - (1 - z**a)**b, z <= 1), (1, True))
```

`sympy.stats.Laplace(name, mu, b)`

Create a continuous random variable with a Laplace distribution.

### Parameters

**mu** : Real number or a list/matrix, the location (mean) or the location vector

**b** : Real number or a positive definite matrix, representing a scale or the covariance matrix.

### Returns

RandomSymbol

## Explanation

The density of the Laplace distribution is given by

$$f(x) := \frac{1}{2b} \exp\left(-\frac{|x - \mu|}{b}\right)$$

## Examples

```
>>> from sympy.stats import Laplace, density, cdf
>>> from sympy import Symbol, pprint
```

```
>>> mu = Symbol("mu")
>>> b = Symbol("b", positive=True)
>>> z = Symbol("z")
```

```
>>> X = Laplace("x", mu, b)
```

```
>>> density(X)(z)
exp(-Abs(mu - z)/b)/(2*b)
```

```
>>> cdf(X)(z)
Piecewise((exp((-mu + z)/b)/2, mu > z), (1 - exp((mu - z)/b)/2, True))
```

```
>>> L = Laplace('L', [1, 2], [[1, 0], [0, 1]])
>>> pprint(density(L)(1, 2), use_unicode=False)
 5 / \
e *besselk\0, \ / 35 /

 pi
```

`sympy.stats.Levy(name, mu, c)`

Create a continuous random variable with a Levy distribution.

The density of the Levy distribution is given by

$$f(x) := \sqrt{\frac{c}{2\pi}} \frac{\exp - \frac{c}{2(x-\mu)}}{(x-\mu)^{3/2}}$$

### Parameters

**mu** : Real number

The location parameter.

**c** : Real number,  $c > 0$

A scale parameter.

### Returns

RandomSymbol

## Examples

```
>>> from sympy.stats import Levy, density, cdf
>>> from sympy import Symbol
```

```
>>> mu = Symbol("mu", real=True)
>>> c = Symbol("c", positive=True)
>>> z = Symbol("z")
```

```
>>> X = Levy("x", mu, c)
```

```
>>> density(X)(z)
sqrt(2)*sqrt(c)*exp(-c/(-2*mu + 2*z))/(2*sqrt(pi)*(-mu + z)**(3/2))
```

```
>>> cdf(X)(z)
erfc(sqrt(c)*sqrt(1/(-2*mu + 2*z)))
```

## References

`sympy.stats.Logistic(name, mu, s)`

Create a continuous random variable with a logistic distribution.

### Parameters

**mu** : Real number, the location (mean)

**s** : Real number,  $s > 0$ , a scale

### Returns

RandomSymbol

## Explanation

The density of the logistic distribution is given by

$$f(x) := \frac{e^{-(x-\mu)/s}}{s(1 + e^{-(x-\mu)/s})^2}$$

## Examples

```
>>> from sympy.stats import Logistic, density, cdf
>>> from sympy import Symbol
```

```
>>> mu = Symbol("mu", real=True)
>>> s = Symbol("s", positive=True)
>>> z = Symbol("z")
```

```
>>> X = Logistic("x", mu, s)
```

```
>>> density(X)(z)
exp((mu - z)/s)/(s*(exp((mu - z)/s) + 1)**2)
```

```
>>> cdf(X)(z)
1/(exp((mu - z)/s) + 1)
```

`sympy.stats.LogLogistic(name, alpha, beta)`

Create a continuous random variable with a log-logistic distribution. The distribution is unimodal when  $\beta > 1$ .

### Parameters

**alpha** : Real number,  $\alpha > 0$ , scale parameter and median of distribution

**beta** : Real number,  $\beta > 0$ , a shape parameter

### Returns

RandomSymbol

## Explanation

The density of the log-logistic distribution is given by

$$f(x) := \frac{(\frac{\beta}{\alpha})(\frac{x}{\alpha})^{\beta-1}}{(1 + (\frac{x}{\alpha})^\beta)^2}$$

## Examples

```
>>> from sympy.stats import LogLogistic, density, cdf, quantile
>>> from sympy import Symbol, pprint
```

```
>>> alpha = Symbol("alpha", positive=True)
>>> beta = Symbol("beta", positive=True)
>>> p = Symbol("p")
>>> z = Symbol("z", positive=True)
```

```
>>> X = LogLogistic("x", alpha, beta)
```

```
>>> D = density(X)(z)
>>> pprint(D, use_unicode=False)
 beta - 1
 / z \
beta*|-----|
 \alpha/

 / beta \
 | / z \ |
alpha*| |-----| + 1 |
 \|alpha/ /
```

```
>>> cdf(X)(z)
1/(1 + (z/alpha)**(-beta))
```

```
>>> quantile(X)(p)
alpha*(p/(1 - p))**(1/beta)
```

## References

[R870]

`sympy.stats.LogNormal`(*name, mean, std*)

Create a continuous random variable with a log-normal distribution.

### Parameters

**mu** : Real number

The log-scale.

**sigma** : Real number

A shape. ( $\sigma^2 > 0$ )

### Returns

RandomSymbol

## Explanation

The density of the log-normal distribution is given by

$$f(x) := \frac{1}{x\sqrt{2\pi\sigma^2}} e^{-\frac{(\ln x - \mu)^2}{2\sigma^2}}$$

with  $x \geq 0$ .

## Examples

```
>>> from sympy.stats import LogNormal, density
>>> from sympy import Symbol, pprint
```

```
>>> mu = Symbol("mu", real=True)
>>> sigma = Symbol("sigma", positive=True)
>>> z = Symbol("z")
```

```
>>> X = LogNormal("x", mu, sigma)
```

```
>>> D = density(X)(z)
>>> pprint(D, use_unicode=False)
```

```
 2
 -(-mu + log(z))

 2
 2*sigma
\ / 2 *e

2*\ / pi *sigma*z
```

```
>>> X = LogNormal('x', 0, 1) # Mean 0, standard deviation 1
```

```
>>> density(X)(z)
sqrt(2)*exp(-log(z)**2/2)/(2*sqrt(pi)*z)
```

## References

[R871], [R872]

`sympy.stats.Lomax(name, alpha, lamda)`

Create a continuous random variable with a Lomax distribution.

### Parameters

**alpha** : Real Number,  $\alpha > 0$

Shape parameter

**lamda** : Real Number,  $\lambda > 0$

Scale parameter

**Returns**

RandomSymbol

**Explanation**

The density of the Lomax distribution is given by

$$f(x) := \frac{\alpha}{\lambda} \left[ 1 + \frac{x}{\lambda} \right]^{-(\alpha+1)}$$

**Examples**

```
>>> from sympy.stats import Lomax, density, cdf, E
>>> from sympy import symbols
>>> a, l = symbols('a, l', positive=True)
>>> X = Lomax('X', a, l)
>>> x = symbols('x')
>>> density(X)(x)
a*(1 + x/l)**(-a - 1)/l
>>> cdf(X)(x)
Piecewise((1 - 1/(1 + x/l)**a, x >= 0), (0, True))
>>> a = 2
>>> X = Lomax('X', a, l)
>>> E(X)
l
```

**References**[\[R873\]](#)

`sympy.stats.Maxwell(name, a)`

Create a continuous random variable with a Maxwell distribution.

**Parameters**

**a** : Real number,  $a > 0$

**Returns**

RandomSymbol

**Explanation**

The density of the Maxwell distribution is given by

$$f(x) := \sqrt{\frac{2}{\pi}} \frac{x^2 e^{-x^2/(2a^2)}}{a^3}$$

with  $x \geq 0$ .

## Examples

```
>>> from sympy.stats import Maxwell, density, E, variance
>>> from sympy import Symbol, simplify
```

```
>>> a = Symbol("a", positive=True)
>>> z = Symbol("z")
```

```
>>> X = Maxwell("x", a)
```

```
>>> density(X)(z)
sqrt(2)*z**2*exp(-z**2/(2*a**2))/(sqrt(pi)*a**3)
```

```
>>> E(X)
2*sqrt(2)*a/sqrt(pi)
```

```
>>> simplify(variance(X))
a**2*(-8 + 3*pi)/pi
```

## References

`sympy.stats.Moyal`(*name*, *mu*, *sigma*)

Create a continuous random variable with a Moyal distribution.

### Parameters

**mu** : Real number

Location parameter

**sigma** : Real positive number

Scale parameter

### Returns

RandomSymbol

## Explanation

The density of the Moyal distribution is given by

$$f(x) := \frac{\exp -\frac{1}{2} \exp -\frac{x-\mu}{\sigma} - \frac{x-\mu}{2\sigma}}{\sqrt{2\pi}\sigma}$$

with  $x \in \mathbb{R}$ .

## Examples

```
>>> from sympy.stats import Moyal, density, cdf
>>> from sympy import Symbol, simplify
>>> mu = Symbol("mu", real=True)
>>> sigma = Symbol("sigma", positive=True, real=True)
>>> z = Symbol("z")
>>> X = Moyal("x", mu, sigma)
>>> density(X)(z)
sqrt(2)*exp(-exp((mu - z)/sigma)/2 - (-mu + z)/(2*sigma))/
 (2*sqrt(pi)*sigma)
>>> simplify(cdf(X)(z))
1 - erf(sqrt(2)*exp((mu - z)/(2*sigma))/2)
```

## References

`sympy.stats.Nakagami(name, mu, omega)`

Create a continuous random variable with a Nakagami distribution.

### Parameters

**mu** : Real number,  $\mu \geq \frac{1}{2}$ , a shape

**omega** : Real number,  $\omega > 0$ , the spread

### Returns

RandomSymbol

## Explanation

The density of the Nakagami distribution is given by

$$f(x) := \frac{2\mu^\mu}{\Gamma(\mu)\omega^\mu} x^{2\mu-1} \exp\left(-\frac{\mu}{\omega}x^2\right)$$

with  $x > 0$ .

## Examples

```
>>> from sympy.stats import Nakagami, density, E, variance, cdf
>>> from sympy import Symbol, simplify, pprint
```

```
>>> mu = Symbol("mu", positive=True)
>>> omega = Symbol("omega", positive=True)
>>> z = Symbol("z")
```

```
>>> X = Nakagami("x", mu, omega)
```

```
>>> D = density(X)(z)
>>> pprint(D, use_unicode=False)

`sympy.stats.Normal(name, mean, std)`

Create a continuous random variable with a Normal distribution.

### Parameters

**mu** : Real number or a list representing the mean or the mean vector

**sigma** : Real number or a positive definite square matrix,

$\sigma^2 > 0$ , the variance

### Returns

RandomSymbol

## Explanation

The density of the Normal distribution is given by

$$f(x) := \frac{1}{\sigma\sqrt{2\pi}} e^{-\frac{(x-\mu)^2}{2\sigma^2}}$$

## Examples

```
>>> from sympy.stats import Normal, density, E, std, cdf, skewness, quantile, marginal_distribution
>>> from sympy import Symbol, simplify, pprint
```

```
>>> mu = Symbol("mu")
>>> sigma = Symbol("sigma", positive=True)
>>> z = Symbol("z")
>>> y = Symbol("y")
>>> p = Symbol("p")
>>> X = Normal("x", mu, sigma)
```

`sympy.stats.Pareto(name, xm, alpha)`

Create a continuous random variable with the Pareto distribution.

### Parameters

**xm** : Real number,  $x_m > 0$ , a scale

**alpha** : Real number,  $\alpha > 0$ , a shape

### Returns

RandomSymbol

## Explanation

The density of the Pareto distribution is given by

$$f(x) := \frac{\alpha x_m^\alpha}{x^{\alpha+1}}$$

with  $x \in [x_m, \infty]$ .

## Examples

```
>>> from sympy.stats import Pareto, density
>>> from sympy import Symbol
```

```
>>> xm = Symbol("xm", positive=True)
>>> beta = Symbol("beta", positive=True)
>>> z = Symbol("z")
```

```
>>> X = Pareto("x", xm, beta)
```

```
>>> density(X)(z)
beta*xm**beta*z**(-beta - 1)
```

`sympy.stats.PowerFunction(name, alpha, a, b)`

Creates a continuous random variable with a Power Function Distribution.

**Parameters**

**alpha** : Positive number,  $0 < \alpha$ , the shape paramater

**a** : Real number,  $-\infty < a$ , the left boundary

**b** : Real number,  $a < b < \infty$ , the right boundary

**Returns**

RandomSymbol

**Explanation**

The density of PowerFunction distribution is given by

$$f(x) := \frac{\alpha(x-a)^{\alpha-1}}{(b-a)^\alpha}$$

with  $x \in [a, b]$ .

**Examples**

```
>>> from sympy.stats import PowerFunction, density, cdf, E, variance
>>> from sympy import Symbol
>>> alpha = Symbol("alpha", positive=True)
>>> a = Symbol("a", real=True)
>>> b = Symbol("b", real=True)
>>> z = Symbol("z")
```

```
>>> X = PowerFunction("X", 2, a, b)
```

```
>>> density(X)(z)
(-2*a + 2*z)/(-a + b)**2
```

```
>>> cdf(X)(z)
Piecewise((a**2/(a**2 - 2*a*b + b**2) - 2*a*z/(a**2 - 2*a*b + b**2) +
z**2/(a**2 - 2*a*b + b**2), a <= z), (0, True))
```

```
>>> alpha = 2
>>> a = 0
>>> b = 1
>>> Y = PowerFunction("Y", alpha, a, b)
```

```
>>> E(Y)
2/3
```

```
>>> variance(Y)
1/18
```

`sympy.stats.QuadraticU(name, a, b)`

Create a Continuous Random Variable with a U-quadratic distribution.

### Parameters

**a** : Real number

**b** : Real number,  $a < b$

### Returns

RandomSymbol

## Explanation

The density of the U-quadratic distribution is given by

$$f(x) := \alpha(x - \beta)^2$$

with  $x \in [a, b]$ .

## Examples

```
>>> from sympy.stats import QuadraticU, density
>>> from sympy import Symbol, pprint
```

```
>>> a = Symbol("a", real=True)
>>> b = Symbol("b", real=True)
>>> z = Symbol("z")
```

```
>>> X = QuadraticU("x", a, b)
```

```
>>> D = density(X)(z)
>>> pprint(D, use_unicode=False)
/

`sympy.stats.RaisedCosine(name, mu, s)`

Create a Continuous Random Variable with a raised cosine distribution.

### Parameters

**mu** : Real number

**s** : Real number,  $s > 0$

### Returns

RandomSymbol

## Explanation

The density of the raised cosine distribution is given by

$$f(x) := \frac{1}{2s} \left( 1 + \cos \left( \frac{x - \mu}{s} \pi \right) \right)$$

with  $x \in [\mu - s, \mu + s]$ .

## Examples

```
>>> from sympy.stats import RaisedCosine, density
>>> from sympy import Symbol, pprint
```

```
>>> mu = Symbol("mu", real=True)
>>> s = Symbol("s", positive=True)
>>> z = Symbol("z")
```

```
>>> X = RaisedCosine("x", mu, s)
```

```
>>> D = density(X)(z)
>>> pprint(D, use_unicode=False)
/ /pi*(-mu + z)\
|cos|-----| + 1

`sympy.stats.Rayleigh(name, sigma)`

Create a continuous random variable with a Rayleigh distribution.

### Parameters

**sigma** : Real number,  $\sigma > 0$

### Returns

RandomSymbol

## Explanation

The density of the Rayleigh distribution is given by

$$f(x) := \frac{x}{\sigma^2} e^{-x^2/2\sigma^2}$$

with  $x > 0$ .

## Examples

```
>>> from sympy.stats import Rayleigh, density, E, variance
>>> from sympy import Symbol
```

```
>>> sigma = Symbol("sigma", positive=True)
>>> z = Symbol("z")
```

```
>>> X = Rayleigh("x", sigma)
```

```
>>> density(X)(z)
z*exp(-z**2/(2*sigma**2))/sigma**2
```

`sympy.stats.Reciprocal(name, a, b)`

Creates a continuous random variable with a reciprocal distribution.

### Parameters

**a** : Real number,  $0 < a$

**b** : Real number,  $a < b$

**Returns**

RandomSymbol

**Examples**

```
>>> from sympy.stats import Reciprocal, density, cdf
>>> from sympy import symbols
>>> a, b, x = symbols('a, b, x', positive=True)
>>> R = Reciprocal('R', a, b)
```

```
>>> density(R)(x)
1/(x*(-log(a) + log(b)))
>>> cdf(R)(x)
Piecewise((log(a)/(log(a) - log(b)) - log(x)/(log(a) - log(b)), a <= x),
 (0, True))
```

**Reference**`sympy.stats.StudentT(name, nu)`

Create a continuous random variable with a student's t distribution.

**Parameters****nu** : Real number,  $\nu > 0$ , the degrees of freedom**Returns**

RandomSymbol

**Explanation**

The density of the student's t distribution is given by

$$f(x) := \frac{\Gamma\left(\frac{\nu+1}{2}\right)}{\sqrt{\nu\pi}\Gamma\left(\frac{\nu}{2}\right)} \left(1 + \frac{x^2}{\nu}\right)^{-\frac{\nu+1}{2}}$$

**Examples**

```
>>> from sympy.stats import StudentT, density, cdf
>>> from sympy import Symbol, pprint
```

```
>>> nu = Symbol("nu", positive=True)
>>> z = Symbol("z")
```

```
>>> X = StudentT("x", nu)
```

```

`sympy.stats.ShiftedGompertz(name, b, eta)`

Create a continuous random variable with a Shifted Gompertz distribution.

### Parameters

**b** : Real number,  $b > 0$ , a scale

**eta** : Real number,  $\eta > 0$ , a shape

### Returns

RandomSymbol

## Explanation

The density of the Shifted Gompertz distribution is given by

$$f(x) := be^{-bx}e^{-\eta \exp(-bx)} \left[1 + \eta(1 - e^{-bx})\right]$$

with  $x \in [0, \infty)$ .

## Examples

```
>>> from sympy.stats import ShiftedGompertz, density
>>> from sympy import Symbol
```

```
>>> b = Symbol("b", positive=True)
>>> eta = Symbol("eta", positive=True)
>>> x = Symbol("x")
```

```
>>> X = ShiftedGompertz("x", b, eta)
```

```
>>> density(X)(x)
b*(eta*(1 - exp(-b*x)) + 1)*exp(-b*x)*exp(-eta*exp(-b*x))
```

[R891]

`sympy.stats.Trapezoidal(name, a, b, c, d)`

Create a continuous random variable with a trapezoidal distribution.

### Parameters

**a** : Real number,  $a < d$

**b** : Real number,  $a \leq b < c$

**c** : Real number,  $b < c \leq d$

**d** : Real number

### Returns

RandomSymbol

## Explanation

The density of the trapezoidal distribution is given by

$$f(x) := \begin{cases} 0 & \text{for } x < a, \\ \frac{2(x-a)}{(b-a)(d+c-a-b)} & \text{for } a \leq x < b, \\ \frac{2}{d+c-a-b} & \text{for } b \leq x < c, \\ \frac{2(d-x)}{(d-c)(d+c-a-b)} & \text{for } c \leq x < d, \\ 0 & \text{for } d < x. \end{cases}$$

## Examples

```
>>> from sympy.stats import Trapezoidal, density
>>> from sympy import Symbol, pprint
```

```
>>> a = Symbol("a")
>>> b = Symbol("b")
>>> c = Symbol("c")
>>> d = Symbol("d")
>>> z = Symbol("z")
```

```
>>> X = Trapezoidal("x", a,b,c,d)
```

```
>>> pprint(density(X)(z), use_unicode=False)
/
-2*a + 2*z
|----- for And(a <= z, b > z)
|(-a + b)*(-a - b + c + d)
```

(continues on next page)

(continued from previous page)

$$\begin{aligned}
 & \frac{2}{-a - b + c + d} && \text{for } \text{And}(b \leq z, c > z) \\
 & \frac{2*d - 2*z}{(-c + d)*(-a - b + c + d)} && \text{for } \text{And}(d \geq z, c \leq z) \\
 & 0 && \text{otherwise}
 \end{aligned}$$

[R892]

`sympy.stats.Triangular(name, a, b, c)`

Create a continuous random variable with a triangular distribution.

### Parameters

**a** : Real number,  $a \in (-\infty, \infty)$

**b** : Real number,  $a < b$

**c** : Real number,  $a \leq c \leq b$

### Returns

RandomSymbol

## Explanation

The density of the triangular distribution is given by

$$f(x) := \begin{cases} 0 & \text{for } x < a, \\ \frac{2(x-a)}{(b-a)(c-a)} & \text{for } a \leq x < c, \\ \frac{2}{b-a} & \text{for } x = c, \\ \frac{2(b-x)}{(b-a)(b-c)} & \text{for } c < x \leq b, \\ 0 & \text{for } b < x. \end{cases}$$

## Examples

```
>>> from sympy.stats import Triangular, density
>>> from sympy import Symbol, pprint
```

```
>>> a = Symbol("a")
>>> b = Symbol("b")
>>> c = Symbol("c")
>>> z = Symbol("z")
```

```
>>> X = Triangular("x", a,b,c)
```

```
>>> pprint(density(X)(z), use_unicode=False)
/ -2*a + 2*z
|----- for And(a <= z, c > z)
| (-a + b)*(-a + c)
|
| 2
|----- for c = z
< -a + b
|
| 2*b - 2*z
|----- for And(b >= z, c < z)
| (-a + b)*(b - c)
|
\ 0
 otherwise
```

`sympy.stats.Uniform(name, left, right)`

Create a continuous random variable with a uniform distribution.

### Parameters

**a** : Real number,  $-\infty < a$ , the left boundary

**b** : Real number,  $a < b < \infty$ , the right boundary

### Returns

RandomSymbol

## Explanation

The density of the uniform distribution is given by

$$f(x) := \begin{cases} \frac{1}{b-a} & \text{for } x \in [a, b] \\ 0 & \text{otherwise} \end{cases}$$

with  $x \in [a, b]$ .

## Examples

```
>>> from sympy.stats import Uniform, density, cdf, E, variance
>>> from sympy import Symbol, simplify
```

```
>>> a = Symbol("a", negative=True)
>>> b = Symbol("b", positive=True)
>>> z = Symbol("z")
```

```
>>> X = Uniform("x", a, b)
```

```
>>> density(X)(z)
Piecewise((1/(-a + b), (b >= z) & (a <= z)), (0, True))
```

```
>>> cdf(X)(z)
Piecewise((0, a > z), ((-a + z)/(-a + b), b >= z), (1, True))
```

```
>>> E(X)
a/2 + b/2
```

```
>>> simplify(variance(X))
a**2/12 - a*b/6 + b**2/12
```

## References

[R895], [R896]

`sympy.stats.UniformSum(name, n)`

Create a continuous random variable with an Irwin-Hall distribution.

### Parameters

**n** : A positive integer,  $n > 0$

### Returns

RandomSymbol

## Explanation

The probability distribution function depends on a single parameter  $n$  which is an integer.

The density of the Irwin-Hall distribution is given by

$$f(x) := \frac{1}{(n-1)!} \sum_{k=0}^{\lfloor x \rfloor} (-1)^k \binom{n}{k} (x-k)^{n-1}$$

## Examples

```
>>> from sympy.stats import UniformSum, density, cdf
>>> from sympy import Symbol, pprint
```

```
>>> n = Symbol("n", integer=True)
>>> z = Symbol("z")
```

```
>>> X = UniformSum("x", n)
```

```
>>> D = density(X)(z)
>>> pprint(D, use_unicode=False)
floor(z)
```

$$\sum_{k=0}^{\lfloor z \rfloor} \frac{(-1)^k (-k + z)^{n-1} \sqrt{n}}{\sqrt{k}}$$

-----

$$(n-1)!$$

```
>>> cdf(X)(z)
Piecewise((0, z < 0), (Sum((-1)**_k*(-_k + z)**n*binomial(n, _k),
(_k, 0, floor(z)))/factorial(n), n >= z), (1, True))
```

Compute cdf with specific 'x' and 'n' values as follows : `>>> cdf(UniformSum("x", 5), evaluate=False)(2).doit()` 9/40

The argument `evaluate=False` prevents an attempt at evaluation of the sum for general `n`, before the argument 2 is passed.

## References

[R897], [R898]

`sympy.stats.VonMises(name, mu, k)`

Create a Continuous Random Variable with a von Mises distribution.

### Parameters

**mu** : Real number

Measure of location.

**k** : Real number

Measure of concentration.

### Returns

RandomSymbol

## Explanation

The density of the von Mises distribution is given by

$$f(x) := \frac{e^{\kappa \cos(x-\mu)}}{2\pi I_0(\kappa)}$$

with  $x \in [0, 2\pi]$ .

## Examples

```
>>> from sympy.stats import VonMises, density
>>> from sympy import Symbol, pprint
```

```
>>> mu = Symbol("mu")
>>> k = Symbol("k", positive=True)
>>> z = Symbol("z")
```

```
>>> X = VonMises("x", mu, k)
```

```
>>> D = density(X)(z)
>>> pprint(D, use_unicode=False)
 k*cos(mu - z)
 e

2*pi*besseli(0, k)
```

## References

[R899], [R900]

`sympy.stats.Wald(name, mean, shape)`

Create a continuous random variable with an Inverse Gaussian distribution. Inverse Gaussian distribution is also known as Wald distribution.

### Parameters

**mu :**

Positive number representing the mean.

**lambda :**

Positive number representing the shape parameter.

### Returns

RandomSymbol

## Explanation

The density of the Inverse Gaussian distribution is given by

$$f(x) := \sqrt{\frac{\lambda}{2\pi x^3}} e^{-\frac{\lambda(x-\mu)^2}{2x\mu^2}}$$

## Examples

```
>>> from sympy.stats import GaussianInverse, density, E, std, skewness
>>> from sympy import Symbol, pprint
```

```
>>> mu = Symbol("mu", positive=True)
>>> lamda = Symbol("lambda", positive=True)
>>> z = Symbol("z", positive=True)
>>> X = GaussianInverse("x", mu, lamda)
```

```
>>> D = density(X)(z)
>>> pprint(D, use_unicode=False)
 2
 -lambda*(-mu + z)

 2
 2*mu *z
\ / 2 * \ / lambda * e

 3/2
2*\ / pi *z
```

```
>>> E(X)
mu
```

```
>>> std(X).expand()
mu**(3/2)/sqrt(lambda)
```

```
>>> skewness(X).expand()
3*sqrt(mu)/sqrt(lambda)
```

## References

[R901], [R902]

`sympy.stats.Weibull(name, alpha, beta)`

Create a continuous random variable with a Weibull distribution.

### Parameters

**lambda** : Real number,  $\lambda > 0$ , a scale

**k** : Real number,  $k > 0$ , a shape

### Returns

RandomSymbol

## Explanation

The density of the Weibull distribution is given by

$$f(x) := \begin{cases} \frac{k}{\lambda} \left(\frac{x}{\lambda}\right)^{k-1} e^{-(x/\lambda)^k} & x \geq 0 \\ 0 & x < 0 \end{cases}$$

## Examples

```
>>> from sympy.stats import Weibull, density, E, variance
>>> from sympy import Symbol, simplify
```

```
>>> l = Symbol("lambda", positive=True)
>>> k = Symbol("k", positive=True)
>>> z = Symbol("z")
```

```
>>> X = Weibull("x", l, k)
```

```
>>> density(X)(z)
k*(z/lambda)**(k - 1)*exp(-(z/lambda)**k)/lambda
```

```
>>> simplify(E(X))
lambda*gamma(1 + 1/k)
```

```
>>> simplify(variance(X))
lambda**2*(-gamma(1 + 1/k)**2 + gamma(1 + 2/k))
```

## References

[R903], [R904]

`sympy.stats.WignerSemicircle(name, R)`

Create a continuous random variable with a Wigner semicircle distribution.

### Parameters

**R** : Real number,  $R > 0$ , the radius

### Returns

A RandomSymbol.

## Explanation

The density of the Wigner semicircle distribution is given by

$$f(x) := \frac{2}{\pi R^2} \sqrt{R^2 - x^2}$$

with  $x \in [-R, R]$ .

## Examples

```
>>> from sympy.stats import WignerSemicircle, density, E
>>> from sympy import Symbol
```

```
>>> R = Symbol("R", positive=True)
>>> z = Symbol("z")
```

```
>>> X = WignerSemicircle("x", R)
```

```
>>> density(X)(z)
2*sqrt(R**2 - z**2)/(pi*R**2)
```

```
>>> E(X)
0
```

## References

[R905], [R906]

`sympy.stats.ContinuousRV(symbol, density, set=Interval(-oo, oo), **kwargs)`

Create a Continuous Random Variable given the following:

### Parameters

**symbol** : Symbol

Represents name of the random variable.

**density** : Expression containing symbol

Represents probability density function.

**set** : set/Interval

Represents the region where the pdf is valid, by default is real line.

**check** : bool

If True, it will check whether the given density integrates to 1 over the given set. If False, it will not perform this check. Default is False.

### Returns

RandomSymbol

Many common continuous random variable types are already implemented.

This function should be necessary only very rarely.

## Examples

```
>>> from sympy import Symbol, sqrt, exp, pi
>>> from sympy.stats import ContinuousRV, P, E
```

```
>>> x = Symbol("x")
```

```
>>> pdf = sqrt(2)*exp(-x**2/2)/(2*sqrt(pi)) # Normal distribution
>>> X = ContinuousRV(x, pdf)
```

```
>>> E(X)
0
>>> P(X>0)
1/2
```

## Joint Types

`sympy.stats.JointRV(symbol, pdf, _set=None)`

Create a Joint Random Variable where each of its component is continuous, given the following:

### Parameters

**symbol** : Symbol

Represents name of the random variable.

**pdf** : A PDF in terms of indexed symbols of the symbol given as the first argument

### Returns

RandomSymbol

## Note

As of now, the set for each component for a JointRV is equal to the set of all integers, which cannot be changed.

## Examples

```
>>> from sympy import exp, pi, Indexed, S
>>> from sympy.stats import density, JointRV
>>> x1, x2 = (Indexed('x', i) for i in (1, 2))
>>> pdf = exp(-x1**2/2 + x1 - x2**2/2 - S(1)/2)/(2*pi)
>>> N1 = JointRV('x', pdf) #Multivariate Normal distribution
>>> density(N1)(1, 2)
exp(-2)/(2*pi)
```

`sympy.stats.marginal_distribution(rv, *indices)`

Marginal distribution function of a joint random variable.

**Parameters**

**rv** : A random variable with a joint probability distribution.

**indices** : Component indices or the indexed random symbol  
for which the joint distribution is to be calculated

**Returns**

A Lambda expression in *sym*.

**Examples**

```
>>> from sympy.stats import MultivariateNormal, marginal_distribution
>>> m = MultivariateNormal('X', [1, 2], [[2, 1], [1, 2]])
>>> marginal_distribution(m, m[0])(1)
1/(2*sqrt(pi))
```

`sympy.stats.MultivariateNormal(name, mu, sigma)`

Creates a continuous random variable with Multivariate Normal Distribution.

The density of the multivariate normal distribution can be found at [1].

**Parameters**

**mu** : List representing the mean or the mean vector

**sigma** : Positive semidefinite square matrix

Represents covariance Matrix. If  $\sigma$  is noninvertible then only sampling is supported currently

**Returns**

RandomSymbol

**Examples**

```
>>> from sympy.stats import MultivariateNormal, density, marginal_
->distribution
>>> from sympy import symbols, MatrixSymbol
>>> X = MultivariateNormal('X', [3, 4], [[2, 1], [1, 2]])
>>> y, z = symbols('y z')
>>> density(X)(y, z)
sqrt(3)*exp(-y**2/3 + y*z/3 + 2*y/3 - z**2/3 + 5*z/3 - 13/3)/(6*pi)
>>> density(X)(1, 2)
sqrt(3)*exp(-4/3)/(6*pi)
>>> marginal_distribution(X, X[1])(y)
exp(-(y - 4)**2/4)/(2*sqrt(pi))
>>> marginal_distribution(X, X[0])(y)
exp(-(y - 3)**2/4)/(2*sqrt(pi))
```

The example below shows that it is also possible to use symbolic parameters to define the MultivariateNormal class.

```
>>> n = symbols('n', integer=True, positive=True)
>>> Sg = MatrixSymbol('Sg', n, n)
>>> mu = MatrixSymbol('mu', n, 1)
>>> obs = MatrixSymbol('obs', n, 1)
>>> X = MultivariateNormal('X', mu, Sg)
```

The density of a multivariate normal can be calculated using a matrix argument, as shown below.

```
>>> density(X)(obs)
(exp(((1/2)*mu.T - (1/2)*obs.T)*Sg**(-1)*(-mu + obs)))/
→sqrt((2*pi)**n*Determinant(Sg)))[0, 0]
```

## References

[R907]

`sympy.stats.MultivariateLaplace(name, mu, sigma)`

Creates a continuous random variable with Multivariate Laplace Distribution.

The density of the multivariate Laplace distribution can be found at [1].

### Parameters

**mu** : List representing the mean or the mean vector

**sigma** : Positive definite square matrix

Represents covariance Matrix

### Returns

RandomSymbol

## Examples

```
>>> from sympy.stats import MultivariateLaplace, density
>>> from sympy import symbols
>>> y, z = symbols('y z')
>>> X = MultivariateLaplace('X', [2, 4], [[3, 1], [1, 3]])
>>> density(X)(y, z)
sqrt(2)*exp(y/4 + 5*z/4)*besselk(0, sqrt(15*y*(3*y/8 - z/8)/2 + 15*z*(-y/
→8 + 3*z/8)/2))/(4*pi)
>>> density(X)(1, 2)
sqrt(2)*exp(11/4)*besselk(0, sqrt(165)/4)/(4*pi)
```

## References

[R908]

`sympy.stats.GeneralizedMultivariateLogGamma(syms, delta, v, lamda, mu)`

Creates a joint random variable with generalized multivariate log gamma distribution.

The joint pdf can be found at [1].

### Parameters

**syms** : list/tuple/set of symbols for identifying each component

**delta** : A constant in range  $[0, 1]$

**v** : Positive real number

**lamda** : List of positive real numbers

**mu** : List of positive real numbers

### Returns

RandomSymbol

## Examples

```
>>> from sympy.stats import density
>>> from sympy.stats.joint_rv_types import GeneralizedMultivariateLogGamma
>>> from sympy import symbols, S
>>> v = 1
>>> l, mu = [1, 1, 1], [1, 1, 1]
>>> d = S.Half
>>> y = symbols('y_1:4', positive=True)
>>> Gd = GeneralizedMultivariateLogGamma('G', d, v, l, mu)
>>> density(Gd)(y[0], y[1], y[2])
Sum(exp((n + 1)*(y_1 + y_2 + y_3) - exp(y_1) - exp(y_2) - exp(y_3))/(2**n*gamma(n + 1)**3), (n, 0, oo))/2
```

## Note

If the `GeneralizedMultivariateLogGamma` is too long to type use,

```
>>> from sympy.stats.joint_rv_types import GeneralizedMultivariateLogGamma as GMVLG
>>> Gd = GMVLG('G', d, v, l, mu)
```

If you want to pass the matrix `omega` instead of the constant `delta`, then use `GeneralizedMultivariateLogGammaOmega`.

## References

[R909], [R910]

`sympy.stats.GeneralizedMultivariateLogGammaOmega(syms, omega, v, lamda, mu)`

Extends GeneralizedMultivariateLogGamma.

### Parameters

**syms** : list/tuple/set of symbols

For identifying each component

**omega** : A square matrix

Every element of square matrix must be absolute value of square root of correlation coefficient

**v** : Positive real number

**lamda** : List of positive real numbers

**mu** : List of positive real numbers

### Returns

RandomSymbol

## Examples

```
>>> from sympy.stats import density
>>> from sympy.stats.joint_rv_types import _
↳ GeneralizedMultivariateLogGammaOmega
>>> from sympy import Matrix, symbols, S
>>> omega = Matrix([[1, S.Half, S.Half], [S.Half, 1, S.Half], [S.Half, S.
↳ Half, 1]])
>>> v = 1
>>> l, mu = [1, 1, 1], [1, 1, 1]
>>> G = GeneralizedMultivariateLogGammaOmega('G', omega, v, l, mu)
>>> y = symbols('y_1:4', positive=True)
>>> density(G)(y[0], y[1], y[2])
sqrt(2)*Sum((1 - sqrt(2)/2)**n*exp((n + 1)*(y_1 + y_2 + y_3) - exp(y_1) -
exp(y_2) - exp(y_3))/gamma(n + 1)**3, (n, 0, oo))/2
```

## Notes

If the GeneralizedMultivariateLogGammaOmega is too long to type use,

```
>>> from sympy.stats.joint_rv_types import _
↳ GeneralizedMultivariateLogGammaOmega as GMVLGO
>>> G = GMVLGO('G', omega, v, l, mu)
```

## References

[R911], [R912]

`sympy.stats.Multinomial(syms, n, *p)`

Creates a discrete random variable with Multinomial Distribution.

The density of the said distribution can be found at [1].

### Parameters

**n** : Positive integer

Represents number of trials

**p** : List of event probabilities

Must be in the range of [0, 1].

### Returns

RandomSymbol

## Examples

```
>>> from sympy.stats import density, Multinomial, marginal_distribution
>>> from sympy import symbols
>>> x1, x2, x3 = symbols('x1, x2, x3', nonnegative=True, integer=True)
>>> p1, p2, p3 = symbols('p1, p2, p3', positive=True)
>>> M = Multinomial('M', 3, p1, p2, p3)
>>> density(M)(x1, x2, x3)
Piecewise((6*p1**x1*p2**x2*p3**x3/
 ↳ (factorial(x1)*factorial(x2)*factorial(x3)),
Eq(x1 + x2 + x3, 3)), (0, True))
>>> marginal_distribution(M, M[0])(x1).subs(x1, 1)
3*p1*p2**2 + 6*p1*p2*p3 + 3*p1*p3**2
```

## References

[R913], [R914]

`sympy.stats.MultivariateBeta(syms, *alpha)`

Creates a continuous random variable with Dirichlet/Multivariate Beta Distribution.

The density of the Dirichlet distribution can be found at [1].

### Parameters

**alpha** : Positive real numbers

Signifies concentration numbers.

### Returns

RandomSymbol

## Examples

```
>>> from sympy.stats import density, MultivariateBeta, marginal_
 ↳distribution
>>> from sympy import Symbol
>>> a1 = Symbol('a1', positive=True)
>>> a2 = Symbol('a2', positive=True)
>>> B = MultivariateBeta('B', [a1, a2])
>>> C = MultivariateBeta('C', a1, a2)
>>> x = Symbol('x')
>>> y = Symbol('y')
>>> density(B)(x, y)
x**(a1 - 1)*y**(a2 - 1)*gamma(a1 + a2)/(gamma(a1)*gamma(a2))
>>> marginal_distribution(C, C[0])(x)
x**(a1 - 1)*gamma(a1 + a2)/(a2*gamma(a1)*gamma(a2))
```

## References

[R915], [R916]

`sympy.stats.MultivariateEwens(syms, n, theta)`

Creates a discrete random variable with Multivariate Ewens Distribution.

The density of the said distribution can be found at [1].

### Parameters

**n** : Positive integer

Size of the sample or the integer whose partitions are considered

**theta** : Positive real number

Denotes Mutation rate

### Returns

RandomSymbol

## Examples

```
>>> from sympy.stats import density, marginal_distribution,
 ↳MultivariateEwens
>>> from sympy import Symbol
>>> a1 = Symbol('a1', positive=True)
>>> a2 = Symbol('a2', positive=True)
>>> ed = MultivariateEwens('E', 2, 1)
>>> density(ed)(a1, a2)
Piecewise((1/(2**a2*factorial(a1)*factorial(a2)), Eq(a1 + 2*a2, 2)), (0,
 ↳True))
>>> marginal_distribution(ed, ed[0])(a1)
Piecewise((1/factorial(a1), Eq(a1, 2)), (0, True))
```

## References

[R917], [R918]

`sympy.stats.MultivariateT(syms, mu, sigma, v)`

Creates a joint random variable with multivariate T-distribution.

### Parameters

**syms** : A symbol/str

For identifying the random variable.

**mu** : A list/matrix

Representing the location vector

**sigma** : The shape matrix for the distribution

### Returns

RandomSymbol

## Examples

```
>>> from sympy.stats import density, MultivariateT
>>> from sympy import Symbol
```

```
>>> x = Symbol("x")
>>> X = MultivariateT("x", [1, 1], [[1, 0], [0, 1]], 2)
```

```
>>> density(X)(1, 2)
2/(9*pi)
```

`sympy.stats.NegativeMultinomial(syms, k0, *p)`

Creates a discrete random variable with Negative Multinomial Distribution.

The density of the said distribution can be found at [1].

### Parameters

**k0** : positive integer

Represents number of failures before the experiment is stopped

**p** : List of event probabilities

Must be in the range of [0, 1]

### Returns

RandomSymbol

## Examples

```
>>> from sympy.stats import density, NegativeMultinomial, marginal_
 ↪distribution
>>> from sympy import symbols
>>> x1, x2, x3 = symbols('x1, x2, x3', nonnegative=True, integer=True)
>>> p1, p2, p3 = symbols('p1, p2, p3', positive=True)
>>> N = NegativeMultinomial('M', 3, p1, p2, p3)
>>> N_c = NegativeMultinomial('M', 3, 0.1, 0.1, 0.1)
>>> density(N)(x1, x2, x3)
p1**x1*p2**x2*p3**x3*(-p1 - p2 - p3 + 1)**3*gamma(x1 + x2 +
x3 + 3)/(2*factorial(x1)*factorial(x2)*factorial(x3))
>>> marginal_distribution(N_c, N_c[0])(1).evalf().round(2)
0.25
```

## References

[R919], [R920]

`sympy.stats.NormalGamma(sym, mu, lamda, alpha, beta)`

Creates a bivariate joint random variable with multivariate Normal gamma distribution.

### Parameters

- sym** : A symbol/str  
For identifying the random variable.
- mu** : A real number  
The mean of the normal distribution
- lamda** : A positive integer  
Parameter of joint distribution
- alpha** : A positive integer  
Parameter of joint distribution
- beta** : A positive integer  
Parameter of joint distribution

### Returns

RandomSymbol

## Examples

```
>>> from sympy.stats import density, NormalGamma
>>> from sympy import symbols
```

```
>>> X = NormalGamma('x', 0, 1, 2, 3)
>>> y, z = symbols('y z')
```

```
>>> density(X)(y, z)
9*sqrt(2)*z**(3/2)*exp(-3*z)*exp(-y**2*z/2)/(2*sqrt(pi))
```

## References

## Stochastic Processes

**class** `sympy.stats.DiscreteMarkovChain`(*sym*, *state\_space=None*, *trans\_probs=None*)

Represents a finite discrete time-homogeneous Markov chain.

This type of Markov Chain can be uniquely characterised by its (ordered) state space and its one-step transition probability matrix.

### Parameters

**sym:**

The name given to the Markov Chain

**state\_space:**

Optional, by default, `Range(n)`

**trans\_probs:**

Optional, by default, `MatrixSymbol('T', n, n)`

## Examples

```
>>> from sympy.stats import DiscreteMarkovChain, TransitionMatrixOf, P, E
>>> from sympy import Matrix, MatrixSymbol, Eq, symbols
>>> T = Matrix([[0.5, 0.2, 0.3],[0.2, 0.5, 0.3],[0.2, 0.3, 0.5]])
>>> Y = DiscreteMarkovChain("Y", [0, 1, 2], T)
>>> YS = DiscreteMarkovChain("Y")
```

```
>>> Y.state_space
{0, 1, 2}
>>> Y.transition_probabilities
Matrix([
[0.5, 0.2, 0.3],
[0.2, 0.5, 0.3],
[0.2, 0.3, 0.5]])
>>> TS = MatrixSymbol('T', 3, 3)
>>> P(Eq(YS[3], 2), Eq(YS[1], 1) & TransitionMatrixOf(YS, TS))
T[0, 2]*T[1, 0] + T[1, 1]*T[1, 2] + T[1, 2]*T[2, 2]
>>> P(Eq(Y[3], 2), Eq(Y[1], 1)).round(2)
0.36
```

Probabilities will be calculated based on indexes rather than state names. For example, with the Sunny-Cloudy-Rainy model with string state names:

```
>>> from sympy.core.symbol import Str
>>> Y = DiscreteMarkovChain("Y", [Str('Sunny'), Str('Cloudy'), Str('Rainy
→')], T)
>>> P(Eq(Y[3], 2), Eq(Y[1], 1)).round(2)
0.36
```

This gives the same answer as the `[0, 1, 2]` state space. Currently, there is no support for state names within probability and expectation statements. Here is a work-around using `Str`:

```
>>> P(Eq(Str('Rainy'), Y[3]), Eq(Y[1], Str('Cloudy'))).round(2)
0.36
```

Symbol state names can also be used:

```
>>> sunny, cloudy, rainy = symbols('Sunny, Cloudy, Rainy')
>>> Y = DiscreteMarkovChain("Y", [sunny, cloudy, rainy], T)
>>> P(Eq(Y[3], rainy), Eq(Y[1], cloudy)).round(2)
0.36
```

Expectations will be calculated as follows:

```
>>> E(Y[3], Eq(Y[1], cloudy))
0.38*Cloudy + 0.36*Rainy + 0.26*Sunny
```

Probability of expressions with multiple `RandomIndexedSymbols` can also be calculated provided there is only 1 `RandomIndexedSymbol` in the given condition. It is always better to use `Rational` instead of floating point numbers for the probabilities in the transition matrix to avoid errors.

```
>>> from sympy import Gt, Le, Rational
>>> T = Matrix([[Rational(5, 10), Rational(3, 10), Rational(2, 10)],
↳ [Rational(2, 10), Rational(7, 10), Rational(1, 10)], [Rational(3, 10),
↳ Rational(3, 10), Rational(4, 10)]]
>>> Y = DiscreteMarkovChain("Y", [0, 1, 2], T)
>>> P(Eq(Y[3], Y[1]), Eq(Y[0], 0)).round(3)
0.409
>>> P(Gt(Y[3], Y[1]), Eq(Y[0], 0)).round(2)
0.36
>>> P(Le(Y[15], Y[10]), Eq(Y[8], 2)).round(7)
0.6963328
```

Symbolic probability queries are also supported

```
>>> a, b, c, d = symbols('a b c d')
>>> T = Matrix([[Rational(1, 10), Rational(4, 10), Rational(5, 10)],
↳ [Rational(3, 10), Rational(4, 10), Rational(3, 10)], [Rational(7, 10),
↳ Rational(2, 10), Rational(1, 10)]]
>>> Y = DiscreteMarkovChain("Y", [0, 1, 2], T)
>>> query = P(Eq(Y[a], b), Eq(Y[c], d))
>>> query.subs({a:10, b:2, c:5, d:1}).round(4)
0.3096
>>> P(Eq(Y[10], 2), Eq(Y[5], 1)).evalf().round(4)
0.3096
>>> query_gt = P(Gt(Y[a], b), Eq(Y[c], d))
>>> query_gt.subs({a:21, b:0, c:5, d:0}).evalf().round(5)
0.64705
>>> P(Gt(Y[21], 0), Eq(Y[5], 0)).round(5)
0.64705
```

There is limited support for arbitrarily sized states:

```

>>> n = symbols('n', nonnegative=True, integer=True)
>>> T = MatrixSymbol('T', n, n)
>>> Y = DiscreteMarkovChain("Y", trans_probs=T)
>>> Y.state_space
Range(0, n, 1)
>>> query = P(Eq(Y[a], b), Eq(Y[c], d))
>>> query.subs({a:10, b:2, c:5, d:1})
(T**5)[1, 2]

```

## References

[R922], [R923]

### absorbing\_probabilities()

Computes the absorbing probabilities, i.e. the  $ij$ -th entry of the matrix denotes the probability of Markov chain being absorbed in state  $j$  starting from state  $i$ .

**canonical\_form()**  $\rightarrow$  Tuple[List[[Basic](#) (page 927)], [ImmutableDenseMatrix](#) (page 1369)]

Reorders the one-step transition matrix so that recurrent states appear first and transient states appear last. Other representations include inserting transient states first and recurrent states last.

#### Returns

states, P\_new

states is the list that describes the order of the new states in the matrix so that the  $i$ th element in states is the state of the  $i$ th row of A. P\_new is the new transition matrix in canonical form.

## Examples

```

>>> from sympy.stats import DiscreteMarkovChain
>>> from sympy import Matrix, S

```

You can convert your chain into canonical form:

```

>>> T = Matrix([[S(1)/2, S(1)/2, 0, 0, 0],
... [S(2)/5, S(1)/5, S(2)/5, 0, 0],
... [0, 0, 1, 0, 0],
... [0, 0, S(1)/2, S(1)/2, 0],
... [S(1)/2, 0, 0, 0, S(1)/2]])
>>> X = DiscreteMarkovChain('X', list(range(1, 6)), trans_probs=T)
>>> states, new_matrix = X.canonical_form()
>>> states
[3, 1, 2, 4, 5]

```

```

>>> new_matrix
Matrix([
[1, 0, 0, 0, 0],
[0, 1/2, 1/2, 0, 0],

```

(continues on next page)

(continued from previous page)

```
[2/5, 2/5, 1/5, 0, 0],
[1/2, 0, 0, 1/2, 0],
[0, 1/2, 0, 0, 1/2]])
```

The new states are [3, 1, 2, 4, 5] and you can create a new chain with this and its canonical form will remain the same (since it is already in canonical form).

```
>>> X = DiscreteMarkovChain('X', states, new_matrix)
>>> states, new_matrix = X.canonical_form()
>>> states
[3, 1, 2, 4, 5]
```

```
>>> new_matrix
Matrix([
[1, 0, 0, 0, 0],
[0, 1/2, 1/2, 0, 0],
[2/5, 2/5, 1/5, 0, 0],
[1/2, 0, 0, 1/2, 0],
[0, 1/2, 0, 0, 1/2]])
```

This is not limited to absorbing chains:

```
>>> T = Matrix([[0, 5, 5, 0, 0],
... [0, 0, 0, 10, 0],
... [5, 0, 5, 0, 0],
... [0, 10, 0, 0, 0],
... [0, 3, 0, 3, 4]])/10
>>> X = DiscreteMarkovChain('X', trans_probs=T)
>>> states, new_matrix = X.canonical_form()
>>> states
[1, 3, 0, 2, 4]
```

```
>>> new_matrix
Matrix([
[0, 1, 0, 0, 0],
[1, 0, 0, 0, 0],
[1/2, 0, 0, 1/2, 0],
[0, 0, 1/2, 1/2, 0],
[3/10, 3/10, 0, 0, 2/5]])
```

[R924], [R925]

**communication\_classes()** → List[Tuple[List[[Basic](#) (page 927)], [Boolean](#) (page 1163), [Integer](#) (page 987)]]

Returns the list of communication classes that partition the states of the markov chain.

A communication class is defined to be a set of states such that every state in that set is reachable from every other state in that set. Due to its properties this forms a class in the mathematical sense. Communication classes are also known as recurrence classes.

### Returns

classes

The classes are a list of tuples. Each tuple represents a single communication class with its properties. The first element in the tuple is the list of states in the class, the second element is whether the class is recurrent and the third element is the period of the communication class.

## Examples

```
>>> from sympy.stats import DiscreteMarkovChain
>>> from sympy import Matrix
>>> T = Matrix([[0, 1, 0],
... [1, 0, 0],
... [1, 0, 0]])
>>> X = DiscreteMarkovChain('X', [1, 2, 3], T)
>>> classes = X.communication_classes()
>>> for states, is_recurrent, period in classes:
... states, is_recurrent, period
([1, 2], True, 2)
([3], False, 1)
```

From this we can see that states 1 and 2 communicate, are recurrent and have a period of 2. We can also see state 3 is transient with a period of 1.

## Notes

The algorithm used is of order  $O(n^2)$  where  $n$  is the number of states in the markov chain. It uses Tarjan's algorithm to find the classes themselves and then it uses a breadth-first search algorithm to find each class's periodicity. Most of the algorithm's components approach  $O(n)$  as the matrix becomes more and more sparse.

[R926], [R927], [R928], [R929]

**decompose()** → Tuple[List[*Basic* (page 927)], *ImmutableDenseMatrix* (page 1369), *ImmutableDenseMatrix* (page 1369), *ImmutableDenseMatrix* (page 1369)]

Decomposes the transition matrix into submatrices with special properties.

The transition matrix can be decomposed into 4 submatrices: - A - the submatrix from recurrent states to recurrent states. - B - the submatrix from transient to recurrent states. - C - the submatrix from transient to transient states. - O - the submatrix of zeros for recurrent to transient states.

### Returns

states, A, B, C

states - a list of state names with the first being the recurrent states and the last being the transient states in the order of the row names of A and then the row names of C. A - the submatrix from recurrent states to recurrent states. B - the submatrix from transient to recurrent states. C - the submatrix from transient to transient states.

## Examples

```
>>> from sympy.stats import DiscreteMarkovChain
>>> from sympy import Matrix, S
```

One can decompose this chain for example:

```
>>> T = Matrix([[S(1)/2, S(1)/2, 0, 0, 0],
... [S(2)/5, S(1)/5, S(2)/5, 0, 0],
... [0, 0, 1, 0, 0],
... [0, 0, S(1)/2, S(1)/2, 0],
... [S(1)/2, 0, 0, 0, S(1)/2]])
>>> X = DiscreteMarkovChain('X', trans_probs=T)
>>> states, A, B, C = X.decompose()
>>> states
[2, 0, 1, 3, 4]
```

```
>>> A # recurrent to recurrent
Matrix([[1]])
```

```
>>> B # transient to recurrent
Matrix([
[0],
[2/5],
[1/2],
[0]])
```

```
>>> C # transient to transient
Matrix([
[1/2, 1/2, 0, 0],
[2/5, 1/5, 0, 0],
```

(continues on next page)

(continued from previous page)

```
[0, 0, 1/2, 0],
[1/2, 0, 0, 1/2]])
```

This means that state 2 is the only absorbing state (since A is a 1x1 matrix). B is a 4x1 matrix since the 4 remaining transient states all merge into recurrent state 2. And C is the 4x4 matrix that shows how the transient states 0, 1, 3, 4 all interact.

**See also:**

**References**

[R930], [R931]

**fixed\_row\_vector()**

A wrapper for `stationary_distribution()`.

**fundamental\_matrix()**

Each entry fundamental matrix can be interpreted as the expected number of times the chains is in state j if it started in state i.

**References**

[R932]

**property limiting\_distribution**

The fixed row vector is the limiting distribution of a discrete Markov chain.

**sample()****Returns**

sample: iterator object

iterator object containing the sample

**stationary\_distribution**(*condition\_set=False*) → Union[[\*ImmutableDenseMatrix\*](#) (page 1369), [\*ConditionSet\*](#) (page 1215), [\*Lambda\*](#) (page 1039)]

The stationary distribution is any row vector,  $p$ , that solves  $p = pP$ , is row stochastic and each element in  $p$  must be nonnegative. That means in matrix form:  $(P - I)^T p^T = 0$  and  $(1, \dots, 1)p = 1$  where  $P$  is the one-step transition matrix.

All time-homogeneous Markov Chains with a finite state space have at least one stationary distribution. In addition, if a finite time-homogeneous Markov Chain is irreducible, the stationary distribution is unique.

**Parameters**

**condition\_set** : bool

If the chain has a symbolic size or transition matrix, it will return a `Lambda` if `False` and return a `ConditionSet` if `True`.

## Examples

```
>>> from sympy.stats import DiscreteMarkovChain
>>> from sympy import Matrix, S
```

An irreducible Markov Chain

```
>>> T = Matrix([[S(1)/2, S(1)/2, 0],
... [S(4)/5, S(1)/5, 0],
... [1, 0, 0]])
>>> X = DiscreteMarkovChain('X', trans_probs=T)
>>> X.stationary_distribution()
Matrix([[8/13, 5/13, 0]])
```

A reducible Markov Chain

```
>>> T = Matrix([[S(1)/2, S(1)/2, 0],
... [S(4)/5, S(1)/5, 0],
... [0, 0, 1]])
>>> X = DiscreteMarkovChain('X', trans_probs=T)
>>> X.stationary_distribution()
Matrix([[8/13 - 8*tau0/13, 5/13 - 5*tau0/13, tau0]])
```

```
>>> Y = DiscreteMarkovChain('Y')
>>> Y.stationary_distribution()
Lambda((wm, _T), Eq(wm*_T, wm))
```

```
>>> Y.stationary_distribution(condition_set=True)
ConditionSet(wm, Eq(wm*_T, wm))
```

### property `transition_probabilities`

Transition probabilities of discrete Markov chain, either an instance of `Matrix` or `MatrixSymbol`.

**class** `sympy.stats.ContinuousMarkovChain(sym, state_space=None, gen_mat=None)`

Represents continuous time Markov chain.

### Parameters

**sym** : Symbol/str

**state\_space** : Set

Optional, by default, `S.Reals`

**gen\_mat** : Matrix/ImmutableMatrix/MatrixSymbol

Optional, by default, `None`

## Examples

```
>>> from sympy.stats import ContinuousMarkovChain, P
>>> from sympy import Matrix, S, Eq, Gt
>>> G = Matrix([[S(1), S(1)], [S(1), -S(1)]])
>>> C = ContinuousMarkovChain('C', state_space=[0, 1], gen_mat=G)
>>> C.limiting_distribution()
Matrix([[1/2, 1/2]])
>>> C.state_space
{0, 1}
>>> C.generator_matrix
Matrix([
[-1, 1],
[1, -1]])
```

Probability queries are supported

```
>>> P(Eq(C(1.96), 0), Eq(C(0.78), 1)).round(5)
0.45279
>>> P(Gt(C(1.7), 0), Eq(C(0.82), 1)).round(5)
0.58602
```

Probability of expressions with multiple RandomIndexedSymbols can also be calculated provided there is only 1 RandomIndexedSymbol in the given condition. It is always better to use Rational instead of floating point numbers for the probabilities in the generator matrix to avoid errors.

```
>>> from sympy import Gt, Le, Rational
>>> G = Matrix([[S(1), Rational(1, 10), Rational(9, 10)], [Rational(2, 5), S(1), Rational(3, 5)], [Rational(1, 2), Rational(1, 2), -S(1)]])
>>> C = ContinuousMarkovChain('C', state_space=[0, 1, 2], gen_mat=G)
>>> P(Eq(C(3.92), C(1.75)), Eq(C(0.46), 0)).round(5)
0.37933
>>> P(Gt(C(3.92), C(1.75)), Eq(C(0.46), 0)).round(5)
0.34211
>>> P(Le(C(1.57), C(3.14)), Eq(C(1.22), 1)).round(4)
0.7143
```

Symbolic probability queries are also supported

```
>>> from sympy import symbols
>>> a,b,c,d = symbols('a b c d')
>>> G = Matrix([[S(1), Rational(1, 10), Rational(9, 10)], [Rational(2, 5), S(1), Rational(3, 5)], [Rational(1, 2), Rational(1, 2), -S(1)]])
>>> C = ContinuousMarkovChain('C', state_space=[0, 1, 2], gen_mat=G)
>>> query = P(Eq(C(a), b), Eq(C(c), d))
>>> query.subs({a:3.65, b:2, c:1.78, d:1}).evalf().round(10)
0.4002723175
>>> P(Eq(C(3.65), 2), Eq(C(1.78), 1)).round(10)
0.4002723175
>>> query_gt = P(Gt(C(a), b), Eq(C(c), d))
>>> query_gt.subs({a:43.2, b:0, c:3.29, d:2}).evalf().round(10)
0.6832579186
```

(continues on next page)

(continued from previous page)

```
>>> P(Gt(C(43.2), 0), Eq(C(3.29), 2)).round(10)
0.6832579186
```

## References

**class** `sympy.stats.BernoulliProcess(sym, p, success=1, failure=0)`

The Bernoulli process consists of repeated independent Bernoulli process trials with the same parameter  $p$ . It's assumed that the probability  $p$  applies to every trial and that the outcomes of each trial are independent of all the rest. Therefore Bernoulli Process is Discrete State and Discrete Time Stochastic Process.

### Parameters

**sym** : Symbol/str

**success** : Integer/str

The event which is considered to be success. Default: 1.

**failure**: Integer/str

The event which is considered to be failure. Default: 0.

**p** : Real Number between 0 and 1

Represents the probability of getting success.

## Examples

```
>>> from sympy.stats import BernoulliProcess, P, E
>>> from sympy import Eq, Gt
>>> B = BernoulliProcess("B", p=0.7, success=1, failure=0)
>>> B.state_space
{0, 1}
>>> (B.p).round(2)
0.70
>>> B.success
1
>>> B.failure
0
>>> X = B[1] + B[2] + B[3]
>>> P(Eq(X, 0)).round(2)
0.03
>>> P(Eq(X, 2)).round(2)
0.44
>>> P(Eq(X, 4)).round(2)
0
>>> P(Gt(X, 1)).round(2)
0.78
>>> P(Eq(B[1], 0) & Eq(B[2], 1) & Eq(B[3], 0) & Eq(B[4], 1)).round(2)
0.04
>>> B.joint_distribution(B[1], B[2])
```

(continues on next page)

(continued from previous page)

```
JointDistributionHandmade(Lambda((B[1], B[2]), Piecewise((0.7, Eq(B[1], 1)),
↳ 1)),
(0.3, Eq(B[1], 0)), (0, True))*Piecewise((0.7, Eq(B[2], 1)), (0.3, 1),
↳ Eq(B[2], 0)),
(0, True))))
>>> E(2*B[1] + B[2]).round(2)
2.10
>>> P(B[1] < 1).round(2)
0.30
```

**expectation**(*expr*, *condition=None*, *evaluate=True*, *\*\*kwargs*)

Computes expectation.

### Parameters

**expr** : RandomIndexedSymbol, Relational, Logic

Condition for which expectation has to be computed. Must contain a RandomIndexedSymbol of the process.

**condition** : Relational, Logic

The given conditions under which computations should be done.

### Returns

Expectation of the RandomIndexedSymbol.

**probability**(*condition*, *given\_condition=None*, *evaluate=True*, *\*\*kwargs*)

Computes probability.

### Parameters

**condition** : Relational

Condition for which probability has to be computed. Must contain a RandomIndexedSymbol of the process.

**given\_condition** : Relational, Logic

The given conditions under which computations should be done.

### Returns

Probability of the condition.

**class** `sympy.stats.PoissonProcess`(*sym*, *lamda*)

The Poisson process is a counting process. It is usually used in scenarios where we are counting the occurrences of certain events that appear to happen at a certain rate, but completely at random.

### Parameters

**sym** : Symbol/str

**lamda** : Positive number

Rate of the process,  $\lambda > 0$

## Examples

```
>>> from sympy.stats import PoissonProcess, P, E
>>> from sympy import symbols, Eq, Ne, Contains, Interval
>>> X = PoissonProcess("X", lamda=3)
>>> X.state_space
Naturals0
>>> X.lamda
3
>>> t1, t2 = symbols('t1 t2', positive=True)
>>> P(X(t1) < 4)
(9*t1**3/2 + 9*t1**2/2 + 3*t1 + 1)*exp(-3*t1)
>>> P(Eq(X(t1), 2) | Ne(X(t1), 4), Contains(t1, Interval.Ropen(2, 4)))
1 - 36*exp(-6)
>>> P(Eq(X(t1), 2) & Eq(X(t2), 3), Contains(t1, Interval.Lopen(0, 2))
... & Contains(t2, Interval.Lopen(2, 4)))
648*exp(-12)
>>> E(X(t1))
3*t1
>>> E(X(t1)**2 + 2*X(t2), Contains(t1, Interval.Lopen(0, 1))
... & Contains(t2, Interval.Lopen(1, 2)))
18
>>> P(X(3) < 1, Eq(X(1), 0))
exp(-6)
>>> P(Eq(X(4), 3), Eq(X(2), 3))
exp(-6)
>>> P(X(2) <= 3, X(1) > 1)
5*exp(-3)
```

### Merging two Poisson Processes

```
>>> Y = PoissonProcess("Y", lamda=4)
>>> Z = X + Y
>>> Z.lamda
7
```

### Splitting a Poisson Process into two independent Poisson Processes

```
>>> N, M = Z.split(l1=2, l2=5)
>>> N.lamda, M.lamda
(2, 5)
```

## Matrix Distributions

`sympy.stats.MatrixGamma(symbol, alpha, beta, scale_matrix)`  
 Creates a random variable with Matrix Gamma Distribution.  
 The density of the said distribution can be found at [1].

### Parameters

**alpha: Positive Real number**

Shape Parameter

**beta: Positive Real number**

Scale Parameter

**scale\_matrix: Positive definite real square matrix**

Scale Matrix

### Returns

RandomSymbol

## Examples

```

>>> from sympy.stats import density, MatrixGamma
>>> from sympy import MatrixSymbol, symbols
>>> a, b = symbols('a b', positive=True)
>>> M = MatrixGamma('M', a, b, [[2, 1], [1, 2]])
>>> X = MatrixSymbol('X', 2, 2)
>>> density(M)(X).doit()
exp(Trace(Matrix([
[-2/3, 1/3],
[1/3, -2/3]])*X)/b)*Determinant(X)**(a - 3/2)/
(3**a*sqrt(pi)*b**(2*a)*gamma(a)*gamma(a - 1/2))
>>> density(M)([[1, 0], [0, 1]]).doit()
exp(-4/(3*b))/(3**a*sqrt(pi)*b**(2*a)*gamma(a)*gamma(a - 1/2))

```

`sympy.stats.Wishart(symbol, n, scale_matrix)`

Creates a random variable with Wishart Distribution.

The density of the said distribution can be found at [1].

### Parameters

**n: Positive Real number**

Represents degrees of freedom

**scale\_matrix: Positive definite real square matrix**

Scale Matrix

### Returns

RandomSymbol

## Examples

```
>>> from sympy.stats import density, Wishart
>>> from sympy import MatrixSymbol, symbols
>>> n = symbols('n', positive=True)
>>> W = Wishart('W', n, [[2, 1], [1, 2]])
>>> X = MatrixSymbol('X', 2, 2)
>>> density(W)(X).doit()
exp(Trace(Matrix([
[-1/3, 1/6],
[1/6, -1/3]])*X))*Determinant(X)**(n/2 - 3/2)/(2**n*3**(n/
- 2)*sqrt(pi)*gamma(n/2)*gamma(n/2 - 1/2))
>>> density(W)([[1, 0], [0, 1]]).doit()
exp(-2/3)/(2**n*3**(n/2)*sqrt(pi)*gamma(n/2)*gamma(n/2 - 1/2))
```

## References

[R945]

`sympy.stats.MatrixNormal(symbol, location_matrix, scale_matrix_1, scale_matrix_2)`

Creates a random variable with Matrix Normal Distribution.

The density of the said distribution can be found at [1].

### Parameters

**location\_matrix: Real ``n x p`` matrix**

Represents degrees of freedom

**scale\_matrix\_1: Positive definite matrix**

Scale Matrix of shape  $n \times n$

**scale\_matrix\_2: Positive definite matrix**

Scale Matrix of shape  $p \times p$

**Returns**

RandomSymbol

**Examples**

```
>>> from sympy import MatrixSymbol
>>> from sympy.stats import density, MatrixNormal
>>> M = MatrixNormal('M', [[1, 2]], [1], [[1, 0], [0, 1]])
>>> X = MatrixSymbol('X', 1, 2)
>>> density(M)(X).doit()
2*exp(-Trace((Matrix([
[-1],
[-2]]) + X.T*(Matrix([[-1, -2]]) + X))/2)/pi
>>> density(M)([[3, 4]]).doit()
2*exp(-4)/pi
```

**References**

[R946]

**Compound Distribution**

**class** sympy.stats.compound\_rv.**CompoundDistribution**(*dist*)

Class for Compound Distributions.

**Parameters**

**dist** : Distribution

Distribution must contain a random parameter

**Examples**

```
>>> from sympy.stats.compound_rv import CompoundDistribution
>>> from sympy.stats.crv_types import NormalDistribution
>>> from sympy.stats import Normal
>>> from sympy.abc import x
>>> X = Normal('X', 2, 4)
>>> N = NormalDistribution(X, 4)
>>> C = CompoundDistribution(N)
>>> C.set
Interval(-oo, oo)
>>> C.pdf(x, evaluate=True).simplify()
exp(-x**2/64 + x/16 - 1/16)/(8*sqrt(pi))
```

## References

[R947]

## Interface

`sympy.stats.P(condition, given_condition=None, numsamples=None, evaluate=True, **kwargs)`

Probability that a condition is true, optionally given a second condition.

### Parameters

**condition** : Combination of Relationals containing RandomSymbols

The condition of which you want to compute the probability

**given\_condition** : Combination of Relationals containing RandomSymbols

A conditional expression.  $P(X > 1, X > 0)$  is expectation of  $X > 1$  given  $X > 0$

**numsamples** : int

Enables sampling and approximates the probability with this many samples

**evaluate** : Bool (defaults to True)

In case of continuous systems return unevaluated integral

## Examples

```
>>> from sympy.stats import P, Die
>>> from sympy import Eq
>>> X, Y = Die('X', 6), Die('Y', 6)
>>> P(X > 3)
1/2
>>> P(Eq(X, 5), X > 2) # Probability that X == 5 given that X > 2
1/4
>>> P(X > Y)
5/12
```

**class** `sympy.stats.Probability(prob, condition=None, **kwargs)`

Symbolic expression for the probability.

## Examples

```
>>> from sympy.stats import Probability, Normal
>>> from sympy import Integral
>>> X = Normal("X", 0, 1)
>>> prob = Probability(X > 1)
>>> prob
Probability(X > 1)
```

Integral representation:

```
>>> prob.rewrite(Integral)
Integral(sqrt(2)*exp(-_z**2/2)/(2*sqrt(pi)), (_z, 1, oo))
```

Evaluation of the integral:

```
>>> prob.evaluate_integral()
sqrt(2)*(-sqrt(2)*sqrt(pi)*erf(sqrt(2)/2) + sqrt(2)*sqrt(pi))/
→ (4*sqrt(pi))
```

`sympy.stats.E(expr, condition=None, numsamples=None, evaluate=True, **kwargs)`

Returns the expected value of a random expression.

#### Parameters

**expr** : Expr containing RandomSymbols

The expression of which you want to compute the expectation value

**given** : Expr containing RandomSymbols

A conditional expression.  $E(X, X > 0)$  is expectation of  $X$  given  $X > 0$

**numsamples** : int

Enables sampling and approximates the expectation with this many samples

**evalf** : Bool (defaults to True)

If sampling return a number rather than a complex expression

**evaluate** : Bool (defaults to True)

In case of continuous systems return unevaluated integral

#### Examples

```
>>> from sympy.stats import E, Die
>>> X = Die('X', 6)
>>> E(X)
7/2
>>> E(2*X + 1)
8
```

```
>>> E(X, X > 3) # Expectation of X given that it is above 3
5
```

**class** `sympy.stats.Expectation(expr, condition=None, **kwargs)`

Symbolic expression for the expectation.

## Examples

```
>>> from sympy.stats import Expectation, Normal, Probability, Poisson
>>> from sympy import symbols, Integral, Sum
>>> mu = symbols("mu")
>>> sigma = symbols("sigma", positive=True)
>>> X = Normal("X", mu, sigma)
>>> Expectation(X)
Expectation(X)
>>> Expectation(X).evaluate_integral().simplify()
mu
```

To get the integral expression of the expectation:

```
>>> Expectation(X).rewrite(Integral)
Integral(sqrt(2)*X*exp(-(X - mu)**2/(2*sigma**2))/(2*sqrt(pi)*sigma), (X,
↪ -oo, oo))
```

The same integral expression, in more abstract terms:

```
>>> Expectation(X).rewrite(Probability)
Integral(x*Probability(Eq(X, x)), (x, -oo, oo))
```

To get the Summation expression of the expectation for discrete random variables:

```
>>> lamda = symbols('lamda', positive=True)
>>> Z = Poisson('Z', lamda)
>>> Expectation(Z).rewrite(Sum)
Sum(Z*lamda**Z*exp(-lamda)/factorial(Z), (Z, 0, oo))
```

This class is aware of some properties of the expectation:

```
>>> from sympy.abc import a
>>> Expectation(a*X)
Expectation(a*X)
>>> Y = Normal("Y", 1, 2)
>>> Expectation(X + Y)
Expectation(X + Y)
```

To expand the Expectation into its expression, use `expand()`:

```
>>> Expectation(X + Y).expand()
Expectation(X) + Expectation(Y)
>>> Expectation(a*X + Y).expand()
a*Expectation(X) + Expectation(Y)
>>> Expectation(a*X + Y)
Expectation(a*X + Y)
>>> Expectation((X + Y)*(X - Y)).expand()
Expectation(X**2) - Expectation(Y**2)
```

To evaluate the Expectation, use `doit()`:

```
>>> Expectation(X + Y).doit()
mu + 1
```

(continues on next page)

(continued from previous page)

```
>>> Expectation(X + Expectation(Y + Expectation(2*X))).doit()
3*mu + 1
```

To prevent evaluating nested Expectation, use `doit(deep=False)`

```
>>> Expectation(X + Expectation(Y)).doit(deep=False)
mu + Expectation(Expectation(Y))
>>> Expectation(X + Expectation(Y + Expectation(2*X))).doit(deep=False)
mu + Expectation(Expectation(Y + Expectation(2*X)))
```

`sympy.stats.density(expr, condition=None, evaluate=True, numsamples=None, **kwargs)`

Probability density of a random expression, optionally given a second condition.

#### Parameters

**expr** : Expr containing RandomSymbols

The expression of which you want to compute the density value

**condition** : Relational containing RandomSymbols

A conditional expression. `density(X > 1, X > 0)` is density of  $X > 1$  given  $X > 0$

**numsamples** : int

Enables sampling and approximates the density with this many samples

#### Explanation

This density will take on different forms for different types of probability spaces. Discrete variables produce Dicts. Continuous variables produce Lambdas.

#### Examples

```
>>> from sympy.stats import density, Die, Normal
>>> from sympy import Symbol
```

```
>>> x = Symbol('x')
>>> D = Die('D', 6)
>>> X = Normal(x, 0, 1)
```

```
>>> density(D).dict
{1: 1/6, 2: 1/6, 3: 1/6, 4: 1/6, 5: 1/6, 6: 1/6}
>>> density(2*D).dict
{2: 1/6, 4: 1/6, 6: 1/6, 8: 1/6, 10: 1/6, 12: 1/6}
>>> density(X)(x)
sqrt(2)*exp(-x**2/2)/(2*sqrt(pi))
```

`sympy.stats.entropy(expr, condition=None, **kwargs)`

Calculates entropy of a probability distribution.

**Parameters**

**expression** : the random expression whose entropy is to be calculated

**condition** : optional, to specify conditions on random expression

**b: base of the logarithm, optional**

By default, it is taken as Euler's number

**Returns**

**result** : Entropy of the expression, a constant

**Examples**

```
>>> from sympy.stats import Normal, Die, entropy
>>> X = Normal('X', 0, 1)
>>> entropy(X)
log(2)/2 + 1/2 + log(pi)/2
```

```
>>> D = Die('D', 4)
>>> entropy(D)
log(4)
```

**References**

[R948], [R949], [R950]

`sympy.stats.given(expr, condition=None, **kwargs)`

Conditional Random Expression.

**Explanation**

From a random expression and a condition on that expression creates a new probability space from the condition and returns the same expression on that conditional probability space.

**Examples**

```
>>> from sympy.stats import given, density, Die
>>> X = Die('X', 6)
>>> Y = given(X, X > 3)
>>> density(Y).dict
{4: 1/3, 5: 1/3, 6: 1/3}
```

Following convention, if the condition is a random symbol then that symbol is considered fixed.

```
>>> from sympy.stats import Normal
>>> from sympy import pprint
>>> from sympy.abc import z
```

```
>>> X = Normal('X', 0, 1)
>>> Y = Normal('Y', 0, 1)
>>> pprint(density(X + Y, Y)(z), use_unicode=False)
 2
 -(-Y + z)

 2
 \ / 2 *e

 2*\ / pi
```

`sympy.stats.where(condition, given_condition=None, **kwargs)`  
Returns the domain where a condition is True.

### Examples

```
>>> from sympy.stats import where, Die, Normal
>>> from sympy import And
```

```
>>> D1, D2 = Die('a', 6), Die('b', 6)
>>> a, b = D1.symbol, D2.symbol
>>> X = Normal('x', 0, 1)
```

```
>>> where(X**2<1)
Domain: (-1 < x) & (x < 1)
```

```
>>> where(X**2<1).set
Interval.open(-1, 1)
```

```
>>> where(And(D1<=D2, D2<3))
Domain: (Eq(a, 1) & Eq(b, 1)) | (Eq(a, 1) & Eq(b, 2)) | (Eq(a, 2) & Eq(b,
↪ 2))
```

`sympy.stats.variance(X, condition=None, **kwargs)`  
Variance of a random expression.

$$\text{variance}(X) = E((X - E(X))^2)$$

### Examples

```
>>> from sympy.stats import Die, Bernoulli, variance
>>> from sympy import simplify, Symbol
```

```
>>> X = Die('X', 6)
>>> p = Symbol('p')
>>> B = Bernoulli('B', p, 1, 0)
```

```
>>> variance(2*X)
35/3
```

```
>>> simplify(variance(B))
p*(1 - p)
```

**class** `sympy.stats.Variance`(*arg*, *condition=None*, *\*\*kwargs*)  
 Symbolic expression for the variance.

## Examples

```
>>> from sympy import symbols, Integral
>>> from sympy.stats import Normal, Expectation, Variance, Probability
>>> mu = symbols("mu", positive=True)
>>> sigma = symbols("sigma", positive=True)
>>> X = Normal("X", mu, sigma)
>>> Variance(X)
Variance(X)
>>> Variance(X).evaluate_integral()
sigma**2
```

Integral representation of the underlying calculations:

```
>>> Variance(X).rewrite(Integral)
Integral(sqrt(2)*(X - Integral(sqrt(2)*X*exp(-(X - mu)**2/(2*sigma**2))/
→ (2*sqrt(pi)*sigma), (X, -oo, oo)))**2*exp(-(X - mu)**2/(2*sigma**2))/
→ (2*sqrt(pi)*sigma), (X, -oo, oo))
```

Integral representation, without expanding the PDF:

```
>>> Variance(X).rewrite(Probability)
-Integral(x*Probability(Eq(X, x)), (x, -oo, oo))**2 +
→ Integral(x**2*Probability(Eq(X, x)), (x, -oo, oo))
```

Rewrite the variance in terms of the expectation

```
>>> Variance(X).rewrite(Expectation)
-Expectation(X)**2 + Expectation(X**2)
```

Some transformations based on the properties of the variance may happen:

```
>>> from sympy.abc import a
>>> Y = Normal("Y", 0, 1)
>>> Variance(a*X)
Variance(a*X)
```

To expand the variance in its expression, use `expand()`:

```
>>> Variance(a*X).expand()
a**2*Variance(X)
>>> Variance(X + Y)
Variance(X + Y)
```

(continues on next page)

(continued from previous page)

```
>>> Variance(X + Y).expand()
2*Covariance(X, Y) + Variance(X) + Variance(Y)
```

`sympy.stats.covariance(X, Y, condition=None, **kwargs)`  
Covariance of two random expressions.

### Explanation

The expectation that the two variables will rise and fall together

$$\text{covariance}(X, Y) = E((X - E(X))(Y - E(Y)))$$

### Examples

```
>>> from sympy.stats import Exponential, covariance
>>> from sympy import Symbol
```

```
>>> rate = Symbol('lambda', positive=True, real=True)
>>> X = Exponential('X', rate)
>>> Y = Exponential('Y', rate)
```

```
>>> covariance(X, X)
lambda**(-2)
>>> covariance(X, Y)
0
>>> covariance(X, Y + rate*X)
1/lambda
```

**class** `sympy.stats.Covariance(arg1, arg2, condition=None, **kwargs)`  
Symbolic expression for the covariance.

### Examples

```
>>> from sympy.stats import Covariance
>>> from sympy.stats import Normal
>>> X = Normal("X", 3, 2)
>>> Y = Normal("Y", 0, 1)
>>> Z = Normal("Z", 0, 1)
>>> W = Normal("W", 0, 1)
>>> cexpr = Covariance(X, Y)
>>> cexpr
Covariance(X, Y)
```

Evaluate the covariance,  $X$  and  $Y$  are independent, therefore zero is the result:

```
>>> cexpr.evaluate_integral()
0
```

Rewrite the covariance expression in terms of expectations:

```
>>> from sympy.stats import Expectation
>>> cexpr.rewrite(Expectation)
Expectation(X*Y) - Expectation(X)*Expectation(Y)
```

In order to expand the argument, use `expand()`:

```
>>> from sympy.abc import a, b, c, d
>>> Covariance(a*X + b*Y, c*Z + d*W)
Covariance(a*X + b*Y, c*Z + d*W)
>>> Covariance(a*X + b*Y, c*Z + d*W).expand()
a*c*Covariance(X, Z) + a*d*Covariance(W, X) + b*c*Covariance(Y, Z) +
→ b*d*Covariance(W, Y)
```

This class is aware of some properties of the covariance:

```
>>> Covariance(X, X).expand()
Variance(X)
>>> Covariance(a*X, b*Y).expand()
a*b*Covariance(X, Y)
```

`sympy.stats.coskewness(X, Y, Z, condition=None, **kwargs)`

Calculates the co-skewness of three random variables.

#### Parameters

**X** : RandomSymbol

Random Variable used to calculate coskewness

**Y** : RandomSymbol

Random Variable used to calculate coskewness

**Z** : RandomSymbol

Random Variable used to calculate coskewness

**condition** : Expr containing RandomSymbols

A conditional expression

#### Returns

**coskewness** : The coskewness of the three random variables

#### Explanation

Mathematically Coskewness is defined as

$$\text{coskewness}(X, Y, Z) = \frac{E[(X - E[X]) * (Y - E[Y]) * (Z - E[Z])]}{\sigma_X \sigma_Y \sigma_Z}$$

## Examples

```
>>> from sympy.stats import coskewness, Exponential, skewness
>>> from sympy import symbols
>>> p = symbols('p', positive=True)
>>> X = Exponential('X', p)
>>> Y = Exponential('Y', 2*p)
>>> coskewness(X, Y, Y)
0
>>> coskewness(X, Y + X, Y + 2*X)
16*sqrt(85)/85
>>> coskewness(X + 2*Y, Y + X, Y + 2*X, X > 3)
9*sqrt(170)/85
>>> coskewness(Y, Y, Y) == skewness(Y)
True
>>> coskewness(X, Y + p*X, Y + 2*p*X)
4/(sqrt(1 + 1/(4*p**2))*sqrt(4 + 1/(4*p**2)))
```

## References

[R951]

`sympy.stats.median(X, evaluate=True, **kwargs)`

Calculates the median of the probability distribution.

### Parameters

**X:** The random expression whose median is to be calculated.

### Returns

The FiniteSet or an Interval which contains the median of the random expression.

## Explanation

Mathematically, median of Probability distribution is defined as all those values of  $m$  for which the following condition is satisfied

$$P(X \leq m) \geq \frac{1}{2} \text{ and } P(X \geq m) \geq \frac{1}{2}$$

## Examples

```
>>> from sympy.stats import Normal, Die, median
>>> N = Normal('N', 3, 1)
>>> median(N)
{3}
>>> D = Die('D')
>>> median(D)
{3, 4}
```

## References

[R952]

`sympy.stats.std(X, condition=None, **kwargs)`

Standard Deviation of a random expression

$$\text{std}(X) = \sqrt{E((X - E(X))^2)}$$

## Examples

```
>>> from sympy.stats import Bernoulli, std
>>> from sympy import Symbol, simplify
```

```
>>> p = Symbol('p')
>>> B = Bernoulli('B', p, 1, 0)
```

```
>>> simplify(std(B))
sqrt(p*(1 - p))
```

`sympy.stats.quantile(expr, evaluate=True, **kwargs)`

Return the  $p^{\text{th}}$  order quantile of a probability distribution.

## Explanation

Quantile is defined as the value at which the probability of the random variable is less than or equal to the given probability.

$$Q(p) = \inf\{x \in (-\infty, \infty) : p \leq F(x)\}$$

## Examples

```
>>> from sympy.stats import quantile, Die, Exponential
>>> from sympy import Symbol, pprint
>>> p = Symbol("p")
```

```
>>> l = Symbol("lambda", positive=True)
>>> X = Exponential("x", l)
>>> quantile(X)(p)
-log(1 - p)/lambda
```

```
>>> D = Die("d", 6)
>>> pprint(quantile(D)(p), use_unicode=False)
/nan for 0<(p > 1, p < 0)
|
| 1 for p <= 1/6
|
| 2 for p <= 1/3
```

(continues on next page)

(continued from previous page)

```
|
< 3 for p <= 1/2
|
| 4 for p <= 2/3
|
| 5 for p <= 5/6
|
\ 6 for p <= 1
```

```
sympy.stats.sample(expr, condition=None, size=(), library='scipy', numsamples=1,
 seed=None, **kwargs)
```

A realization of the random expression.

### Parameters

**expr** : Expression of random variables

Expression from which sample is extracted

**condition** : Expr containing RandomSymbols

A conditional expression

**size** : int, tuple

Represents size of each sample in numsamples

**library** : str

- 'scipy' : Sample using scipy
- 'numpy' : Sample using numpy
- 'pymc' : Sample using PyMC

Choose any of the available options to sample from as string, by default is 'scipy'

**numsamples** : int

Number of samples, each with size as size.

Deprecated since version 1.9.

The numsamples parameter is deprecated and is only provided for compatibility with v1.8. Use a list comprehension or an additional dimension in size instead. See [sympy.stats.sample\(numsamples=n\)](#) (page 168) for details.

**seed** :

An object to be used as seed by the given external library for sampling *expr*. Following is the list of possible types of object for the supported libraries,

- 'scipy': int, numpy.random.RandomState,  
numpy.random.Generator
- 'numpy': int, numpy.random.RandomState,  
numpy.random.Generator
- 'pymc': int

Optional, by default None, in which case seed settings related to the given library will be used. No modifications to environment's global seed settings are done by this argument.

**Returns**

sample: float/list/numpy.ndarray

one sample or a collection of samples of the random expression.

- sample(X) returns float/numpy.float64/numpy.int64 object.
- sample(X, size=int/tuple) returns numpy.ndarray object.

**Examples**

```
>>> from sympy.stats import Die, sample, Normal, Geometric
>>> X, Y, Z = Die('X', 6), Die('Y', 6), Die('Z', 6) # Finite Random
↳Variable
>>> die_roll = sample(X + Y + Z)
>>> die_roll
3
>>> N = Normal('N', 3, 4) # Continuous Random Variable
>>> samp = sample(N)
>>> samp in N.pspace.domain.set
True
>>> samp = sample(N, N>0)
>>> samp > 0
True
>>> samp_list = sample(N, size=4)
>>> [sam in N.pspace.domain.set for sam in samp_list]
[True, True, True, True]
>>> sample(N, size = (2,3))
array([[5.42519758, 6.40207856, 4.94991743],
 [1.85819627, 6.83403519, 1.9412172]])
>>> G = Geometric('G', 0.5) # Discrete Random Variable
>>> samp_list = sample(G, size=3)
>>> samp_list
[1, 3, 2]
>>> [sam in G.pspace.domain.set for sam in samp_list]
[True, True, True]
>>> MN = Normal("MN", [3, 4], [[2, 1], [1, 2]]) # Joint Random Variable
>>> samp_list = sample(MN, size=4)
>>> samp_list
[array([2.85768055, 3.38954165]),
 array([4.11163337, 4.3176591]),
 array([0.79115232, 1.63232916]),
 array([4.01747268, 3.96716083])]
>>> [tuple(sam) in MN.pspace.domain.set for sam in samp_list]
[True, True, True, True]
```

Changed in version 1.7.0: sample used to return an iterator containing the samples instead of value.

Changed in version 1.9.0: sample returns values or array of values instead of an iterator and numsamples is deprecated.

`sympy.stats.sample_iter(expr, condition=None, size=(), library='scipy',  
numsamples=oo, seed=None, **kwargs)`

Returns an iterator of realizations from the expression given a condition.

#### Parameters

**expr: Expr**

Random expression to be realized

**condition: Expr, optional**

A conditional expression

**size : int, tuple**

Represents size of each sample in numsamples

**numsamples: integer, optional**

Length of the iterator (defaults to infinity)

**seed :**

An object to be used as seed by the given external library for sampling *expr*. Following is the list of possible types of object for the supported libraries,

- 'scipy': int, numpy.random.RandomState,  
numpy.random.Generator
- 'numpy': int, numpy.random.RandomState,  
numpy.random.Generator
- 'pymc': int

Optional, by default None, in which case seed settings related to the given library will be used. No modifications to environment's global seed settings are done by this argument.

#### Returns

sample\_iter: iterator object

iterator object containing the sample/samples of given expr

#### Examples

```
>>> from sympy.stats import Normal, sample_iter
>>> X = Normal('X', 0, 1)
>>> expr = X*X + 3
>>> iterator = sample_iter(expr, numsamples=3)
>>> list(iterator)
[12, 4, 7]
```

#### See also:

[sample](#) (page 2971), [sampling\\_P](#) (page 2976), [sampling\\_E](#) (page 2976)

`sympy.stats.factorial_moment(X, n, condition=None, **kwargs)`

The factorial moment is a mathematical quantity defined as the expectation or average of the falling factorial of a random variable.

$$\text{factorial-moment}(X, n) = E(X(X-1)(X-2)\dots(X-n+1))$$

**Parameters****n**: A natural number, n-th factorial moment.**condition** : Expr containing RandomSymbols

A conditional expression.

**Examples**

```
>>> from sympy.stats import factorial_moment, Poisson, Binomial
>>> from sympy import Symbol, S
>>> lamda = Symbol('lamda')
>>> X = Poisson('X', lamda)
>>> factorial_moment(X, 2)
lamda**2
>>> Y = Binomial('Y', 2, S.Half)
>>> factorial_moment(Y, 2)
1/2
>>> factorial_moment(Y, 2, Y > 1) # find factorial moment for Y > 1
2
```

**References**[\[R953\]](#), [\[R954\]](#)`sympy.stats.kurtosis(X, condition=None, **kwargs)`

Characterizes the tails/outliers of a probability distribution.

**Parameters****condition** : Expr containing RandomSymbolsA conditional expression. `kurtosis(X, X>0)` is kurtosis of X given  $X > 0$ **Explanation**

Kurtosis of any univariate normal distribution is 3. Kurtosis less than 3 means that the distribution produces fewer and less extreme outliers than the normal distribution.

$$kurtosis(X) = E(((X - E(X))/\sigma_X)^4)$$

**Examples**

```
>>> from sympy.stats import kurtosis, Exponential, Normal
>>> from sympy import Symbol
>>> X = Normal('X', 0, 1)
>>> kurtosis(X)
3
>>> kurtosis(X, X > 0) # find kurtosis given X > 0
(-4/pi - 12/pi**2 + 3)/(1 - 2/pi)**2
```

```
>>> rate = Symbol('lamda', positive=True, real=True)
>>> Y = Exponential('Y', rate)
>>> kurtosis(Y)
9
```

## References

[R955], [R956]

`sympy.stats.skewness(X, condition=None, **kwargs)`

Measure of the asymmetry of the probability distribution.

### Parameters

**condition** : Expr containing RandomSymbols

A conditional expression. `skewness(X, X>0)` is skewness of X given  $X > 0$

## Explanation

Positive skew indicates that most of the values lie to the right of the mean.

$$\text{skewness}(X) = E(((X - E(X))/\sigma_X)^3)$$

## Examples

```
>>> from sympy.stats import skewness, Exponential, Normal
>>> from sympy import Symbol
>>> X = Normal('X', 0, 1)
>>> skewness(X)
0
>>> skewness(X, X > 0) # find skewness given X > 0
(-sqrt(2)/sqrt(pi) + 4*sqrt(2)/pi**(3/2))/(1 - 2/pi)**(3/2)
```

```
>>> rate = Symbol('lambda', positive=True, real=True)
>>> Y = Exponential('Y', rate)
>>> skewness(Y)
2
```

`sympy.stats.correlation(X, Y, condition=None, **kwargs)`

Correlation of two random expressions, also known as correlation coefficient or Pearson's correlation.

## Explanation

The normalized expectation that the two variables will rise and fall together

$$\text{correlation}(X, Y) = E((X - E(X))(Y - E(Y)) / (\sigma_x \sigma_y))$$

## Examples

```
>>> from sympy.stats import Exponential, correlation
>>> from sympy import Symbol
```

```
>>> rate = Symbol('lambda', positive=True, real=True)
>>> X = Exponential('X', rate)
>>> Y = Exponential('Y', rate)
```

```
>>> correlation(X, X)
1
>>> correlation(X, Y)
0
>>> correlation(X, Y + rate*X)
1/sqrt(1 + lambda**(-2))
```

`sympy.stats.rv.sampling_density(expr, given_condition=None, library='scipy', numsamples=1, seed=None, **kwargs)`

Sampling version of density.

### See also:

[density](#) (page 2963), [sampling\\_P](#) (page 2976), [sampling\\_E](#) (page 2976)

`sympy.stats.rv.sampling_P(condition, given_condition=None, library='scipy', numsamples=1, evalf=True, seed=None, **kwargs)`

Sampling version of P.

### See also:

[P](#) (page 2960), [sampling\\_E](#) (page 2976), [sampling\\_density](#) (page 2976)

`sympy.stats.rv.sampling_E(expr, given_condition=None, library='scipy', numsamples=1, evalf=True, seed=None, **kwargs)`

Sampling version of E.

### See also:

[P](#) (page 2960), [sampling\\_P](#) (page 2976), [sampling\\_density](#) (page 2976)

**class** `sympy.stats.Moment(X, n, c=0, condition=None, **kwargs)`

Symbolic class for Moment

## Examples

```
>>> from sympy import Symbol, Integral
>>> from sympy.stats import Normal, Expectation, Probability, Moment
>>> mu = Symbol('mu', real=True)
>>> sigma = Symbol('sigma', positive=True)
>>> X = Normal('X', mu, sigma)
>>> M = Moment(X, 3, 1)
```

To evaluate the result of Moment use *doit*:

```
>>> M.doit()
mu**3 - 3*mu**2 + 3*mu*sigma**2 + 3*mu - 3*sigma**2 - 1
```

Rewrite the Moment expression in terms of Expectation:

```
>>> M.rewrite(Expectation)
Expectation((X - 1)**3)
```

Rewrite the Moment expression in terms of Probability:

```
>>> M.rewrite(Probability)
Integral((x - 1)**3*Probability(Eq(X, x)), (x, -oo, oo))
```

Rewrite the Moment expression in terms of Integral:

```
>>> M.rewrite(Integral)
Integral(sqrt(2)*(X - 1)**3*exp(-(X - mu)**2/(2*sigma**2))/
 ↳ (2*sqrt(pi)*sigma), (X, -oo, oo))
```

`sympy.stats.moment(X, n, c=0, condition=None, *, evaluate=True, **kwargs)`

Return the nth moment of a random expression about c.

$$\text{moment}(X, c, n) = E((X - c)^n)$$

Default value of c is 0.

## Examples

```
>>> from sympy.stats import Die, moment, E
>>> X = Die('X', 6)
>>> moment(X, 1, 6)
-5/2
>>> moment(X, 2)
91/6
>>> moment(X, 1) == E(X)
True
```

`class sympy.stats.CentralMoment(X, n, condition=None, **kwargs)`

Symbolic class Central Moment

## Examples

```
>>> from sympy import Symbol, Integral
>>> from sympy.stats import Normal, Expectation, Probability,
↳ CentralMoment
>>> mu = Symbol('mu', real=True)
>>> sigma = Symbol('sigma', positive=True)
>>> X = Normal('X', mu, sigma)
>>> CM = CentralMoment(X, 4)
```

To evaluate the result of CentralMoment use *doit*:

```
>>> CM.doit().simplify()
3*sigma**4
```

Rewrite the CentralMoment expression in terms of Expectation:

```
>>> CM.rewrite(Expectation)
Expectation((X - Expectation(X))**4)
```

Rewrite the CentralMoment expression in terms of Probability:

```
>>> CM.rewrite(Probability)
Integral((x - Integral(x*Probability(True), (x, -oo,
↳ oo)))**4*Probability(Eq(X, x)), (x, -oo, oo))
```

Rewrite the CentralMoment expression in terms of Integral:

```
>>> CM.rewrite(Integral)
Integral(sqrt(2)*(X - Integral(sqrt(2)*X*exp(-(X - mu)**2/(2*sigma**2))/
↳ (2*sqrt(pi)*sigma), (X, -oo, oo)))**4*exp(-(X - mu)**2/(2*sigma**2))/
↳ (2*sqrt(pi)*sigma), (X, -oo, oo))
```

`sympy.stats.cmoment(X, n, condition=None, *, evaluate=True, **kwargs)`

Return the *n*th central moment of a random expression about its mean.

$$cmoment(X, n) = E((X - E(X))^n)$$

## Examples

```
>>> from sympy.stats import Die, cmoment, variance
>>> X = Die('X', 6)
>>> cmoment(X, 3)
0
>>> cmoment(X, 2)
35/12
>>> cmoment(X, 2) == variance(X)
True
```

**class** `sympy.stats.ExpectationMatrix(expr, condition=None)`

Expectation of a random matrix expression.

## Examples

```
>>> from sympy.stats import ExpectationMatrix, Normal
>>> from sympy.stats.rv import RandomMatrixSymbol
>>> from sympy import symbols, MatrixSymbol, Matrix
>>> k = symbols("k")
>>> A, B = MatrixSymbol("A", k, k), MatrixSymbol("B", k, k)
>>> X, Y = RandomMatrixSymbol("X", k, 1), RandomMatrixSymbol("Y", k, 1)
>>> ExpectationMatrix(X)
ExpectationMatrix(X)
>>> ExpectationMatrix(A*X).shape
(k, 1)
```

To expand the expectation in its expression, use `expand()`:

```
>>> ExpectationMatrix(A*X + B*Y).expand()
A*ExpectationMatrix(X) + B*ExpectationMatrix(Y)
>>> ExpectationMatrix((X + Y)*(X - Y).T).expand()
ExpectationMatrix(X*X.T) - ExpectationMatrix(X*Y.T) +
↳ ExpectationMatrix(Y*X.T) - ExpectationMatrix(Y*Y.T)
```

To evaluate the `ExpectationMatrix`, use `doit()`:

```
>>> N11, N12 = Normal('N11', 11, 1), Normal('N12', 12, 1)
>>> N21, N22 = Normal('N21', 21, 1), Normal('N22', 22, 1)
>>> M11, M12 = Normal('M11', 1, 1), Normal('M12', 2, 1)
>>> M21, M22 = Normal('M21', 3, 1), Normal('M22', 4, 1)
>>> x1 = Matrix([[N11, N12], [N21, N22]])
>>> x2 = Matrix([[M11, M12], [M21, M22]])
>>> ExpectationMatrix(x1 + x2).doit()
Matrix([
[12, 14],
[24, 26]])
```

**class** `sympy.stats.VarianceMatrix`(*arg*, *condition=None*)

Variance of a random matrix probability expression. Also known as Covariance matrix, auto-covariance matrix, dispersion matrix, or variance-covariance matrix.

## Examples

```
>>> from sympy.stats import VarianceMatrix
>>> from sympy.stats.rv import RandomMatrixSymbol
>>> from sympy import symbols, MatrixSymbol
>>> k = symbols("k")
>>> A, B = MatrixSymbol("A", k, k), MatrixSymbol("B", k, k)
>>> X, Y = RandomMatrixSymbol("X", k, 1), RandomMatrixSymbol("Y", k, 1)
>>> VarianceMatrix(X)
VarianceMatrix(X)
>>> VarianceMatrix(X).shape
(k, k)
```

To expand the variance in its expression, use `expand()`:

```
>>> VarianceMatrix(A*X).expand()
A*VarianceMatrix(X)*A.T
>>> VarianceMatrix(A*X + B*Y).expand()
2*A*CrossCovarianceMatrix(X, Y)*B.T + A*VarianceMatrix(X)*A.T +
↳ B*VarianceMatrix(Y)*B.T
```

**class** `sympy.stats.CrossCovarianceMatrix(arg1, arg2, condition=None)`  
Covariance of a random matrix probability expression.

### Examples

```
>>> from sympy.stats import CrossCovarianceMatrix
>>> from sympy.stats.rv import RandomMatrixSymbol
>>> from sympy import symbols, MatrixSymbol
>>> k = symbols("k")
>>> A, B = MatrixSymbol("A", k, k), MatrixSymbol("B", k, k)
>>> C, D = MatrixSymbol("C", k, k), MatrixSymbol("D", k, k)
>>> X, Y = RandomMatrixSymbol("X", k, 1), RandomMatrixSymbol("Y", k, 1)
>>> Z, W = RandomMatrixSymbol("Z", k, 1), RandomMatrixSymbol("W", k, 1)
>>> CrossCovarianceMatrix(X, Y)
CrossCovarianceMatrix(X, Y)
>>> CrossCovarianceMatrix(X, Y).shape
(k, k)
```

To expand the covariance in its expression, use `expand()`:

```
>>> CrossCovarianceMatrix(X + Y, Z).expand()
CrossCovarianceMatrix(X, Z) + CrossCovarianceMatrix(Y, Z)
>>> CrossCovarianceMatrix(A*X, Y).expand()
A*CrossCovarianceMatrix(X, Y)
>>> CrossCovarianceMatrix(A*X, B.T*Y).expand()
A*CrossCovarianceMatrix(X, Y)*B
>>> CrossCovarianceMatrix(A*X + B*Y, C.T*Z + D.T*W).expand()
A*CrossCovarianceMatrix(X, W)*D + A*CrossCovarianceMatrix(X, Z)*C +
↳ B*CrossCovarianceMatrix(Y, W)*D + B*CrossCovarianceMatrix(Y, Z)*C
```

## Mechanics

SymPy Stats employs a relatively complex class hierarchy.

RandomDomains are a mapping of variables to possible values. For example, we might say that the symbol `Symbol('x')` can take on the values  $\{1, 2, 3, 4, 5, 6\}$ .

**class** `sympy.stats.rv.RandomDomain`

A PSpace, or Probability Space, combines a RandomDomain with a density to provide probabilistic information. For example the above domain could be enhanced by a finite density  $\{1:1/6, 2:1/6, 3:1/6, 4:1/6, 5:1/6, 6:1/6\}$  to fully define the roll of a fair die named `x`.

**class** `sympy.stats.rv.PSpace`

A `RandomSymbol` represents the `PSpace`'s symbol 'x' inside of SymPy expressions.

```
class sympy.stats.rv.RandomSymbol
```

The `RandomDomain` and `PSpace` classes are almost never directly instantiated. Instead they are subclassed for a variety of situations.

`RandomDomains` and `PSpaces` must be sufficiently general to represent domains and spaces of several variables with arbitrarily complex densities. This generality is often unnecessary. Instead we often build `SingleDomains` and `SinglePSpaces` to represent single, univariate events and processes such as a single die or a single normal variable.

```
class sympy.stats.rv.SinglePSpace
```

```
class sympy.stats.rv.SingleDomain
```

Another common case is to collect together a set of such univariate random variables. A collection of independent `SinglePSpaces` or `SingleDomains` can be brought together to form a `ProductDomain` or `ProductPSpace`. These objects would be useful in representing three dice rolled together for example.

```
class sympy.stats.rv.ProductDomain
```

```
class sympy.stats.rv.ProductPSpace
```

The `Conditional` adjective is added whenever we add a global condition to a `RandomDomain` or `PSpace`. A common example would be three independent dice where we know their sum to be greater than 12.

```
class sympy.stats.rv.ConditionalDomain
```

We specialize further into `Finite` and `Continuous` versions of these classes to represent finite (such as dice) and continuous (such as normals) random variables.

```
class sympy.stats.frv.FiniteDomain
```

```
class sympy.stats.frv.FinitePSpace
```

```
class sympy.stats.crv.ContinuousDomain
```

```
class sympy.stats.crv.ContinuousPSpace
```

Additionally there are a few specialized classes that implement certain common random variable types. There is for example a `DiePSpace` that implements `SingleFinitePSpace` and a `NormalPSpace` that implements `SingleContinuousPSpace`.

```
class sympy.stats.frv_types.DiePSpace
```

```
class sympy.stats.crv_types.NormalPSpace
```

`RandomVariables` can be extracted from these objects using the `PSpace.values` method.

As previously mentioned SymPy Stats employs a relatively complex class structure. Inheritance is widely used in the implementation of end-level classes. This tactic was chosen to balance between the need to allow SymPy to represent arbitrarily defined random variables and optimizing for common cases. This complicates the code but is structured to only be important to those working on extending SymPy Stats to other random variable types.

Users will not use this class structure. Instead these mechanics are exposed through variable creation functions `Die`, `Coin`, `FiniteRV`, `Normal`, `Exponential`, etc.... These build the appropriate `SinglePSpaces` and return the corresponding `RandomVariable`. `Conditional` and `Product`

spaces are formed in the natural construction of SymPy expressions and the use of interface functions `E`, `Given`, `Density`, etc....

`sympy.stats.Die()`

`sympy.stats.Normal()`

There are some additional functions that may be useful. They are largely used internally.

`sympy.stats.rv.random_symbols(expr)`

Returns all RandomSymbols within a SymPy Expression.

`sympy.stats.rv.pspace(expr)`

Returns the underlying Probability Space of a random expression.

For internal use.

### Examples

```
>>> from sympy.stats import pspace, Normal
>>> X = Normal('X', 0, 1)
>>> pspace(2*X + 1) == X.pspace
True
```

`sympy.stats.rv.rs_swap(a, b)`

Build a dictionary to swap RandomSymbols based on their underlying symbol.

i.e. if  $X = ('x', \text{pspace1})$  and  $Y = ('x', \text{pspace2})$  then  $X$  and  $Y$  match and the key, value pair  $\{X:Y\}$  will appear in the result

Inputs: collections  $a$  and  $b$  of random variables which share common symbols Output: dict mapping RVs in  $a$  to RVs in  $b$

## CONTRIBUTING

The contributing guide goes over the details necessary to contribute to SymPy. See also the full [Development Workflow](#) guide on the SymPy wiki.

### Content

## 6.1 Development Environment Setup

The first step to contributing to the code base is creating your development environment.

### 6.1.1 Git Setup

SymPy is available on [GitHub](#) and uses [Git](#) for source control. The workflow is such that code is pulled and pushed to and from the main repository. Install the respective version of Git for your operating system to start development.

---

**Note:** Refer to the installation instructions in the [Git installation instructions](#). Learn about the basic git commands in this [Git Handbook](#) or any other sources on the internet.

---

### 6.1.2 Get the SymPy Code

It is recommended practice to create a fork of the SymPy project for your development purposes. Create your own fork of the SymPy project (if you have not yet). Go to the SymPy GitHub repository:

```
https://github.com/sympy/sympy
```

You will now have a fork at `<https://github.com/<your-user-name>/sympy>`.

Then, on your machine browse to where you would like to store SymPy, and clone (download) the latest code from SymPy's original repository (about 77 MiB):

```
$ git clone https://github.com/<your-user-name>/sympy
```

You must [configure the remote repositories](#) for collaboration with the upstream project:

```
$ cd sympy
$ git remote add upstream https://github.com/sympy/sympy
```

After the configuration, your setup should be similar to this:

```
$ git remote -v
origin https://github.com/<your-user-name>/sympy (fetch)
origin https://github.com/<your-user-name>/sympy (push)
upstream https://github.com/sympy/sympy (fetch)
upstream https://github.com/sympy/sympy (push)
```

For further development, it is recommended to create a development branch.

```
$ git checkout -b dev-branch
```

The new branch can be of any name.

### 6.1.3 Virtual Environment Setup

You may want to take advantage of using virtual environments to isolate your development version of SymPy from any system wide installed versions, e.g. from `apt-get install python-sympy`.

We recommend using `conda` to create a virtual environment:

```
$ conda create -n sympy-dev python=3 mpmath flake8
```

You now have a environment that you can use for testing your development copy of SymPy. For example, clone your SymPy fork from Github:

```
$ git clone git@github.com:<your-github-username>/sympy.git
$ cd sympy
```

Now activate the environment:

```
$ conda activate sympy-dev
```

### 6.1.4 Run the Tests

There are several ways of running SymPy tests but the easiest is to use the `bin/test` script, consult 'the wiki details on running tests <<https://github.com/sympy/sympy/wiki/Running-tests>>'.

The script takes a number of options and arguments and then passes them to `sympy.test(*paths, **kwargs)`. Run `bin/test --help` for all supported arguments.

Run all tests by using the command:

```
$ bin/test
```

To run tests for a specific file, use:

```
$ bin/test test_basic
```

Where `test_basic` is from file `sympy/core/basic.py`.

To run tests for modules, use:

```
$ bin/test /core /utilities
```

This will run tests for the `core` and `utilities` modules.

Similarly, run quality tests with:

```
$ bin/test code_quality
```

## 6.2 Dependencies

This page lists the hard and optional dependencies of SymPy.

There are several packages that, when installed, can enable certain additional SymPy functionality. Most users and contributors will not need to install any of the packages mentioned below (except for the hard dependencies), unless they intend to use or contribute to the parts of SymPy that can use those packages.

Every dependency listed below can be installed with `conda` via [conda-forge](#), and most can also be installed with `pip`.

This page does not list packages which themselves depend on SymPy, only those packages that SymPy depends on. An incomplete list of packages that depend on SymPy can be found on the [main SymPy webpage](#), and a more complete list can be found on [GitHub](#) or [libraries.io](#).

### 6.2.1 Hard Dependencies

SymPy only has one hard dependency, which is required for it to work: `mpmath`.

- **mpmath:** [mpmath](#) is a pure Python package for arbitrary precision arithmetic. It is used under the hood whenever SymPy calculates the floating-point value of a function, e.g., when using [evalf](#) (page 1065).

SymPy cannot function without `mpmath` and will fail to import if it is not installed. If you get an error like

```
ImportError: SymPy now depends on mpmath as an external library. See
https://docs.sympy.org/latest/install.html#mpmath for more information.
```

this means that you did not install `mpmath` correctly. [This page](#) (page 2) explains how to install it.

Most methods of installing SymPy, such as the ones outlined in the [installation](#) (page 1) guide, will install `mpmath` automatically. You typically only need to install `mpmath` manually if you did not actually install SymPy, e.g., if you are developing directly on SymPy in the git repository.

## 6.2.2 Optional Dependencies

These dependencies are not required to use SymPy. The vast majority of SymPy functions do not require them, however, a few functions such as plotting and automatic wrapping of code generated functions require additional dependencies to function.

Additionally, as a contributor, when running the SymPy tests, some tests will be skipped if a dependency they require is not installed. The [GitHub Actions CI](#) which is run on every SymPy pull request will automatically install these dependencies in the “optional-dependencies” build, but you may wish to install them locally if you are working on a part of SymPy that uses them.

### Recommended Optional Dependencies

These dependencies are not required for SymPy to function, but it is recommended that all users install them if they can, as they will improve the general performance of SymPy.

- **gmpy2:** [gmpy2](#) is a Python wrapper for the [GMP multiple-precision library](#). It provides large integers that are faster than the built-in Python `int`. When `gmpy2` is installed, it is used automatically by certain core functions that operate on integers, such as the [polys](#) (page 2341). See [Reference docs for the Poly Domains](#) (page 2504) for more details. SymPy uses `gmpy2` automatically when it is installed. No further action is required to enable it.

The polys themselves are used by many parts of SymPy, such as the integration algorithms, simplification algorithms like `collect()` and `factor()`, the matrices, and some parts of the core. Thus, installing `gmpy2` can speed up many parts of SymPy. It is not a required dependency of SymPy because it makes use of a non-Python library (GMP), which is also non-BSD licensed. However, we recommended all users who are able to to install `gmpy2` to get a better SymPy experience.

### Interactive Use

SymPy is designed to be used both interactively and as a library. When used interactively, SymPy is able to interface with IPython and Jupyter notebooks.

- **IPython:** The [init\\_session\(\)](#) (page 2117) function and `isympy` command will automatically start IPython if it is installed. In addition to the usual benefits of using [IPython](#), this enables interactive plotting with `matplotlib`. Also some flags such as `auto_symbols` and `auto_int_to_Integer` will only work in IPython.

The IPython package is required to run some of the tests in `sympy/interactive`.

- **Jupyter Notebook and Qt Console:** SymPy expressions automatically print using MathJax in the [Jupyter Notebook](#) and with LaTeX [Qt Console](#) (if [LaTeX](#) (page 2987) is installed).

## Printing

The `preview()` (page 2181) function automatically converts SymPy expressions into images rendered with LaTeX. `preview()` can either save the image to a file or show it with a viewer.

- **LaTeX:** A  $\text{\LaTeX}$  distributions such as [TeXLive](#) or [MiKTeX](#) is required for `preview()` (page 2181) to function.

## Parsing

Several functions in the `sympy.parsing` (page 2122) submodule require external dependencies to function. Note that not all parsers require external modules at this time. The Python (`parse_expr()` (page 2122)), Mathematica (`parse_mathematica()` (page 2125)), and Maxima (`parse_maxima()` (page 2125)) parsers do not require any external dependencies.

- **antlr-python-runtime:** [Antlr](#) is used for the [LaTeX parser](#) (page 2129) and [Autolev](#) (page 1724) parsers. They both require the Antlr Python runtime to be installed. The package for this is called `antlr-python-runtime` with conda and `antlr4-python3-runtime` with pip). Also be aware that the version of the Antlr Python runtime must match the version that was used to compile the LaTeX and Autolev parsers (4.10).
- **Clang Python Bindings:** The C parser (`sympy.parsing.c.parse_c`) requires the Clang Python bindings. The package for this is called `python-clang` with conda and `clang` with pip.
- **lfortran:** The Fortran parser (in `sympy.parsing.fortran`) requires [LFortran](#).

## Logic

The `satisfiable()` (page 1184) function includes a pure Python implementation of the DPLL satisfiability algorithm. But it can optionally use faster C SAT solvers if they are installed. Note that `satisfiable()` is also used by `ask()` (page 191).

- **pycosat:** [Pycosat](#) is used automatically if it is installed. The use of pycosat can be forced by using `satisfiable(algorithm='pycosat')`.
- **pysat:** [Pysat](#) is a library which wraps many SAT solvers. It can also be used as a backend to `satisfiable()`. Presently, only [Minisat](#) is implemented, using `satisfiable(algorithm=minisat22')`.

## Plotting

The `sympy.plotting.plot` (page 2820) module makes heavy use of external plotting libraries to render plots. The primary plotting module that is supported is Matplotlib.

- **matplotlib:** Most plotting functionality requires the [Matplotlib](#) plotting library. Without Matplotlib installed, most plotting functions will either fail or give rudimentary [text plots](#) (page 2872).
- **pyglet:** SymPy has a submodule `sympy.plotting.pygletplot` (page 2869) that can be used to interface with the [pyglet](#) module to do 2D and 3D plotting.

## lambdify

`lambdify()` (page 2100) is a function that converts SymPy expressions into functions that can be evaluated numerically using various libraries as backends. `lambdify` is the primary vehicle by which users interface between SymPy and these libraries. It is the standard way to convert a symbolic SymPy expression into an evaluable numeric function.

In principle, `lambdify` can interface with any external library if the user passes in an appropriate namespace dictionary as the third argument, but by default, `lambdify` is aware of several popular numeric Python libraries. These libraries are enabled as backends in `lambdify` with build-in translations to convert SymPy expressions into the appropriate functions for those libraries.

- **NumPy:** By default, if it is installed, `lambdify` creates functions using `NumPy` (if `NumPy` is not installed, `lambdify` produces functions using the standard library `math` module, although this behavior is primarily provided for backwards compatibility).
- **SciPy:** If `SciPy` is installed, `lambdify` will use it automatically. `SciPy` is needed to `lambdify` certain [special functions](#) that are not included in `NumPy`.
- **CuPy:** `CuPy` is a library that provides a `NumPy` compatible interface for CUDA GPUs. `lambdify` can produce `CuPy` compatible functions using `lambdify(modules='cupy')`.
- **Jax:** `JAX` is a library that uses XLA to compile and run `NumPy` programs on GPUs and TPUs. `lambdify` can produce `JAX` compatible functions using `lambdify(modules='jax')`.
- **TensorFlow:** `TensorFlow` is a popular machine learning library. `lambdify` can produce `TensorFlow` compatible functions using `lambdify(modules='tensorflow')`.
- **NumExpr:** `NumExpr` is a fast numerical expression evaluator for `NumPy`. `lambdify` can produce `NumExpr` compatible functions using `lambdify(modules='numexpr')`.
- **mpmath:** `lambdify` can also produce `mpmath` compatible functions. Note that `mpmath` is already a [required dependency](#) (page 2985) of SymPy. This functionality is useful for converting a SymPy expression to a function for use with pure `mpmath`.

## Code Generation

SymPy can [generate code](#) (page 1108) for a large number of languages by converting SymPy expressions into valid code for those languages. It also has functionality for some languages to automatically compile and run the code.

Note that the dependencies below are **not** a list of supported languages that SymPy can generate code for. Rather it is a list of packages that SymPy can interface with in some way. For most languages that SymPy supports code generation, it simply generates a string representing the code for that language, so no dependency on that language is required to use the code generation functionality. A dependency is typically only required for features that automatically take the generated code and compile it to a function that can be used within Python. Note that `lambdify()` (page 2100) is a special case of this, but its dependencies are listed [above](#) (page 2988).

## Autowrap

- **NumPy:** NumPy and, optionally, its subpackage `f2py`, can be used to generate Python functions using the `autowrap()` (page 2041) or `ufuncify()` (page 2043) functions.
- **Cython:** Cython can be used as a backend for `autowrap()` (page 2041) or `ufuncify()` (page 2043). Cython is also used in some of the `sympy.codegen` tests to compile some examples.
- **Compilers:** `autowrap()` (page 2041), `ufuncify()` (page 2043), and related functions rely on a compiler to compile the generated code to a function. Most standard C, C++, and Fortran compilers are supported, including Clang/LLVM, GCC, and ifort.

## Code Printers

Most code printers generate Python strings, and therefore do not require the given library or language compiler as a dependency. However, a few code printers generate Python functions instead of strings:

- **Aesara:** The `sympy.printing.aesaracode` (page 2166) module contains functions to convert SymPy expressions into a functions using the Aesara (previously Theano) library. The Aesara code generation functions return Aesara graph objects.
- **llvmlite:** The `sympy.printing.llvmjitcode` module supports generating LLVM Jit from a SymPy expression. The functions make use of `llvmlite`, a Python wrapper around LLVM. The `llvm_callable()` function generates callable functions.
- **TensorFlow:** The `sympy.printing.tensorflow` module supports generating functions using the TensorFlow, a popular machine learning library. Unlike the above two examples, `tensorflow_code()` function **does** generate Python strings. However, `tensorflow` is imported if available in order to automatically detect the TensorFlow version. If it is not installed, the `tensorflow_code()` function assumes the latest supported version of TensorFlow.

## Testing-Only Dependencies

- **Wurlitzer:** Wurlitzer is a Python package that allows capturing output from C extensions. It is used by some of the tests in the `sympy.codegen` submodule. It is only used by the test suite. It is not used by any end-user functionality. If it is not installed, some tests will be skipped.
- **Cython:** Cython is also used in some of the `sympy.codegen` tests to compile some examples.
- **Compilers:** The various *compilers* (page 2989) mentioned above are used in some of the codegen and autowrap tests if they are installed.

## Statistics

The `sympy.stats.sample()` (page 2971) function uses an external library to produce samples from the given distribution. At least one of the following libraries is required to use the sampling functionality of `sympy.stats`.

- **SciPy**: `sample(library='scipy')` is the default. This uses `scipy.stats`.
- **NumPy**: `sample(library='numpy')` uses the `NumPy random` module.
- **pymc**: `sample(library='pymc')` uses `PyMC` to do sampling.

## Optional SymEngine Backend

- **python-symengine**: `SymEngine` is a fast symbolic manipulation library, written in C++. The SymEngine Python bindings may be used as an optional backend for SymPy core. To do this, first install the SymEngine Python bindings (with `pip install symengine` or `conda install -c conda-forge python-symengine`) and run SymPy with the `USE_SYMENGINE=1` environment variable.

Presently, the SymEngine backend is only used by the `sympy.physics.mechanics` (page 1675) and `sympy.liealgebras` (page 2326) modules, although you can also interface with SymPy's SymEngine backend directly by importing things from `sympy.core.backend`:

```
>>> from sympy.core.backend import Symbol
>>> # This will create a SymEngine Symbol object if the USE_SYMENGINE
>>> # environment variable is configured. Otherwise it will be an
↳ ordinary
>>> # SymPy Symbol object.
>>> x = Symbol('x')
```

SymEngine backend support is still experimental, so certain SymPy functions may not work correctly when it is enabled.

## Experimental Rubi Integrator

- **MatchPy**: `MatchPy` is a library for doing pattern matching. It is used in the experimental `sympy.integrals.rubi` module, but presently, it is not used anywhere else in SymPy. SymPy and MatchPy are able to interface with each other.

## Sage

`Sage` is an open source mathematics software that incorporates a large number of open source mathematics libraries. SymPy is one of the libraries used by Sage.

Most of the code that interfaces between SymPy and Sage is in Sage itself, but a few `_sage_` methods in SymPy that do some very basic setting up of the Sage/SymPy wrappers. These methods should typically only be called by Sage itself.

### 6.2.3 Development Dependencies

Typical development on SymPy does not require any additional dependencies beyond Python and mpmath.

#### Getting the Source Code

- **git:** The [SymPy source code](#) uses the [git](#) version control system. See the [installation guide](#) (page 1) and [development workflow](#) for instructions on how to get the development version of SymPy from git.

#### Running the Tests

The base SymPy tests do not require any additional dependencies, however most of the above dependencies may be required for some tests to run. Tests that depend on optional dependencies should be skipped when they are not installed, either by using the `sympy.testing.pytest.skip()` function or by setting `skip = True` to skip the entire test file. Optional modules in tests and SymPy library code should be imported with `import_module()`.

- **pytest:** [Pytest](#) is not a required dependency for the SymPy test suite. SymPy has its own test runner, which can be accessed via the `bin/test` script in the SymPy source directory or the [test\(\)](#) (page 2035) function.

However, if you prefer to use `pytest`, you can use it to run the tests instead of the SymPy test runner. Tests in SymPy should use the wrappers in [sympy.testing.pytest](#) (page 2027) instead of using `pytest` functions directly.

- **Cloudpickle:** The [cloudpickle](#) package can be used to more effectively pickle SymPy objects than the built-in Python [pickle](#). Some tests in `sympy.utilities.tests.test_pickling.py` depend on `cloudpickle` to run. It is not otherwise required for any SymPy function.

#### Building the Documentation

Building the documentation requires several additional dependencies. [This page](#) (page 2992) outlines these dependencies and how to install them. It is only necessary to install these dependencies if you are contributing documentation to SymPy and want to check that the HTML or PDF documentation renders correctly. If you only want to view the documentation for the development version of SymPy, development builds of the docs are hosted online at <https://docs.sympy.org/dev/index.html>.

#### Running the Benchmarks

The benchmarks for SymPy are hosted at [https://github.com/sympy/sympy\\_benchmarks](https://github.com/sympy/sympy_benchmarks). The [README](#) in that repository explains how to run the benchmarks.

Note that the benchmarks are also run automatically on the [GitHub Actions CI](#), so it is generally not necessary to run them yourself as a contributor unless you want to reproduce the benchmarks results on your computer or add a new benchmark to the suite.

- **asv:** [Airspeed Velocity](#) is the package used for running the benchmarks. Note that the package name that you install is called `asv`.

## 6.3 Build the Documentation

Start by installing the required dependencies for the documentation.

### 6.3.1 Required dependencies

You can either install the dependencies locally on your machine, or you can build a Docker image containing them.

#### Docker

If you have [Docker](#), then instead of following the OS-specific installation instructions below, you may choose to build a Docker image:

```
cd doc
docker build -f Dockerfile.html doc -t sympy_html doc .
```

If you choose this option, you can now skip down to the “Build the Docs” section below.

#### Debian/Ubuntu

For Debian/Ubuntu:

```
apt-get install python3-sphinx texlive-latex-recommended dvipng librsvg2-bin
→imagemagick docbook2x graphviz
python -m pip install -r doc/requirements.txt
```

If you get mpmath error, install python-mpmath package:

```
apt-get install python-mpmath
```

If you get matplotlib error, install python-matplotlib package:

```
apt-get install python-matplotlib
```

#### Fedora

For Fedora (and maybe other RPM-based distributions), install the prerequisites:

```
dnf install python3-sphinx librsvg2 ImageMagick docbook2X texlive-dvipng-bin
texlive-scheme-medium librsvg2-tools
python -m pip install -r doc/requirements.txt
```

If you get mpmath error, install python3-mpmath package:

```
dnf install python3-mpmath
```

If you get matplotlib error, install python3-matplotlib package:

```
dnf install python3-matplotlib
```

## Mac

For Mac, first install homebrew: <https://brew.sh/>

Then install these packages with homebrew:

```
brew install imagemagick graphviz docbook librsvg
```

Install the docs dependencies with either pip or conda:

```
python -m pip install -r requirements.txt
```

Or:

```
conda install -c conda-forge --file requirements.txt
```

Making your Sphinx build successful on the Windows system is tricky because some dependencies like dvipng or docbook2x are not available.

## Windows 10

For Windows 10, however, the Windows Subsystem for Linux can be a possible workaround solution, and you can install Ubuntu shell on your Windows system after following the tutorial below:

<https://github.com/MicrosoftDocs/WSL/blob/live/WSL/install-win10.md>

In your command prompt, run `ubuntu` to transfer to Linux terminal, and follow the Debian/Ubuntu tutorial above to install the dependencies, and then you can run `make html` to build. (Note that you also have to install `make` via `apt-get install make`.)

If you want to change the directory in your prompt to your working folder of SymPy in the Windows file system, you can prepend `cd /mnt/` to your file path in Windows, and run in your shell to navigate to the folder. (Also note that Linux uses `/` instead of `\` for file paths.)

This method provides better compatibility than Cygwin or MSYS2 and more convenience than a virtual machine if you partially need a Linux environment for your workflow, however this method is only viable for Windows 10 64-bit users.

or

Follow [instruction](#) to install Chocolatey

Install `make` and other dependencies:

```
choco install make graphviz rsvg-convert imagemagick
```

Install python dependencies:

```
pip install -r doc/requirements.txt
```

## 6.3.2 Build the Docs

### Docker

If you chose to build using Docker, and followed the instructions above to build the `sympy_html doc` image, then you can build the docs with:

```
docker run --rm -v /absolute/path/to/sympy:/sympy sympy_html doc
```

(Be sure to substitute the actual absolute filesystem path to sympy!) This command can be run from any directory.

### Local Installation

If you chose to follow OS-specific instructions above and installed the required dependencies locally, the documentation can be built by running the makefile in the `doc` subdirectory:

```
cd doc
make html
```

### SymPy Logos

SymPy has a collection of official logos, which can be generated from `sympy.svg` in your local copy of SymPy by:

```
$ cd doc
$ make logo # will be stored in the _build/logo subdirectory
```

The license of all the logos is the same as SymPy: BSD. See the [LICENSE file](#) for more information.

## 6.3.3 View the Docs

Once you have built the docs, the generated files will be found under `doc/_build/html`. To view them in your preferred web browser, use the drop down menu and select “open file”, navigate into the `sympy/doc/_build/html` folder, and open the `index.html` file.

## 6.3.4 Auto-Rebuild with the Live Server

The instructions given above told you how to build the docs once, and load them in the browser. After you make changes to the document sources, you’ll have to manually repeat the build step, and reload the pages in the browser.

There is an alternative approach that sets up a live server, which will monitor the docs directory, automatically rebuild when changes are detected, and automatically reload the page you are viewing in the browser.

If you want to use this option, the procedure again depends on whether you are using Docker, or a local installation.

## Docker

To start the live server with Docker, you can use:

```
docker run --rm -it \
 -v /absolute/path/to/sympy:/sympy \
 -p 8000:80 \
 sympy_html doc live
```

and then navigate your browser to `localhost:8000`. You can use a different port by changing the 8000 in the command. Again, be sure to substitute the actual absolute filesystem path to sympy.

When finished, you can stop the server with `ctrl-c` in the terminal.

Alternatively, you may run the server in detached mode, using:

```
docker run --rm -d --name=sympy-livehtml \
 -v /absolute/path/to/sympy:/sympy \
 -p 8000:80 \
 sympy_html doc live
```

and then stop it with:

```
docker stop sympy-livehtml
```

## Local Installation

If you installed the build dependencies locally, then simply use:

```
cd doc
make livehtml
```

to start the server. Your web browser should then automatically open a new tab, showing the index page of the SymPy docs.

When you are finished, you can use `ctrl-c` in the terminal to stop the server.

### 6.3.5 PDF Documentation

---

**Note:** It is not necessary for the majority of contributors to build the PDF documentation. The PDF documentation will be built automatically on GitHub Actions on pull requests. PDF documentation for each release is included on the [GitHub releases page](#).

If the PDF documentation build fails on GitHub Actions, 99% of the time this is due to bad LaTeX math formatting. Double check that any math you have added is formatted correctly, and make sure you use ``double backticks`` for code (single backticks will render as math, not code). See the resources in the [style guide](#) (page 3013) for tips on formatting LaTeX math.

---

Building the PDF documentation requires a few extra dependencies. First you will need to have a TeXLive installation that includes XeLaTeX and latexmk. You will also need to have Chrome or Chromium installed, as it is used to convert some SVG files for the PDF.

On Ubuntu, you can install these with:

```
apt-get install chromium-browser texlive texlive-xetex texlive-fonts-
→recommended texlive-latex-extra latexmk lmodern
```

On Mac, you can use:

```
brew install texlive
brew install --cask chromium
brew tap homebrew/cask-fonts
brew install font-dejavu
```

On Windows 10, you can use:

```
choco install chromium strawberryperl miktex dejavufonts
```

If DejaVu fonts are not installed in C:\Windows\Fonts, then open ~\AppData\Local\Microsoft\Windows\Fonts, select all DejaVu fonts, right-click and click Install for all users.

To build the pdf docs run:

```
cd doc
make pdf
```

The resulting PDF will be in:

```
_build/latex/sympy-<version>.pdf
```

where <version> is the SymPy version (e.g., sympy-1.10.dev.pdf).

## 6.4 Debugging

To start sympy in debug mode set the SYMPY\_DEBUG variable. For instance in a unix-like system you would do

```
$ SYMPY_DEBUG=True bin/isympy
```

or in Windows

```
> set SYMPY_DEBUG=True > python bin/isympy
```

Now just use for example the `limit()` function. You will get a nice printed tree, which is very useful for debugging.

## 6.5 SymPy Docstrings Style Guide

### 6.5.1 General Guidelines

To contribute to SymPy's docstrings, please read these guidelines in full.

A documentation string (docstring) is a string literal that occurs as the first statement in a module, function, class, or method definition. Such a docstring becomes the `__doc__` special attribute of that object.

#### Example

Here is a basic docstring:

```
def fdiff(self, argindex=1):
 """
 Returns the first derivative of a Heaviside Function.

 Examples
 =====

 >>> from sympy import Heaviside, diff
 >>> from sympy.abc import x

 >>> Heaviside(x).fdiff()
 DiracDelta(x)

 >>> Heaviside(x**2 - 1).fdiff()
 DiracDelta(x**2 - 1)

 >>> diff(Heaviside(x)).fdiff()
 DiracDelta(x, 1)

 """
```

Every public function, class, method, and module should have a docstring that describes what it does. Documentation that is specific to a function or class in the module should be in the docstring of that function or class. The module level docstring should discuss the purpose and scope of the module, and give a high-level example of how to use the functions or classes in the module. A module docstring is the docstring at the very top of the file, for example, the docstring for [solvers.ode](#).

A public function is one that is intended to be used by the end- user, or the public. Documentation is important for public functions because they will be seen and used by many people.

A private function, on the other hand, is one that is only intended to be used in the code in SymPy itself. Although it is less important to document private functions, it also helps to have docstrings on private functions to help other SymPy developers understand how to use the function.

It may not always be clear what is a public function and what is a private function. If a function begins with an underscore, it is private, and if a function is included in `__init__.py` it is public, but the converse is not always true, so sometimes you have to decide based on context. In general, if you are unsure, having documentation on a function is better than not having documentation, regardless if it is public or private.

Docstrings should contain information aimed at users of the function. Comments specific to the code or other notes that would only distract users should go in comments in the code, not in docstrings.

Every docstring should have examples that show how the function works. Examples are the most important part of a docstring. A single example showing input and output to a function can be more helpful than a paragraph of descriptive text.

Remember that the primary consumers of docstrings are other human beings, not machines, so it is important to describe what the function does in plain English. Likewise, examples of how to use the function should be designed for human readers, not just for the doctest machinery.

Keep in mind that while Sphinx is the primary way users consume docstrings, and therefore the first platform to keep in mind while writing docstrings (especially for public functions), it is not the only way users consume docstrings. You can also view docstrings using `help()` or `?` in IPython. When using `help()`, for instance, it will show you all of the docstrings on private methods. Additionally, anyone reading the source code directly will see every docstring.

All public functions, classes, and methods and their corresponding docstrings should be imported into the Sphinx docs, instructions on which can be found at the end of this guide.

## 6.5.2 Formatting

Docstrings are written in [reStructuredText](#) format extended by [Sphinx](#). Here is a concise guide to [Quick reStructuredText](#). More in-depth information about using reStructuredText can be found in the [Sphinx Documentation](#).

In order for Sphinx to render docstrings nicely in the HTML documentation, some formatting guidelines should be followed when writing docstrings:

- Always use `"""triple double quotes"""` around docstrings. Use `r"""raw triple double quotes"""` if you use any backslashes in your docstrings.
- Include a blank line before the docstring's closing quotes.
- Lines should not be longer than 80 characters.
- Always write class-level docstrings under the class definition line, as that is better to read in the source code.
- The various methods on the class can be mentioned in the docstring or examples if they are important, but details on them should go in the docstring for the method itself.
- Be aware that `::` creates code blocks, which are rarely used in the docstrings. Any code example with example Python should be put in a doctest. Always check that the final version as rendered by Sphinx looks correct in the HTML.
- In order to make section underlining work nicely in docstrings, [numpydoc Sphinx extension](#) is used.
- Always double check that you have formatted your docstring correctly:

1. Make sure that your docstring is imported into Sphinx.
2. Build the Sphinx docs (`cd doc; make html`).
3. Make sure that Sphinx doesn't output any errors.
4. Open the page in `_build/html` and make sure that it is formatted correctly.

### 6.5.3 Sections

In SymPy’s docstrings, it is preferred that function, class, and method docstrings consist of the following sections in this order:

1. Single-Sentence Summary
2. Explanation
3. Examples
4. Parameters
5. See Also
6. References

The Single-Sentence Summary and Examples sections are **required** for every docstring. Docstrings will not pass review if these sections are not included.

Do not change the names of these supported sections, for example, the heading “Examples” as a plural should be used even if there is only one example.

SymPy will continue to support all of the section headings listed in the [NumPy Docstring Guide](#).

Headings should be underlined with the same length in equals signs.

If a section is not required and that information for the function in question is unnecessary, do not use it. Unnecessary sections and cluttered docstrings can make a function harder to understand. Aim for the minimal amount of information required to understand the function.

#### 1. Single-Sentence Summary

This section is **required** for every docstring. A docstring will not pass review if it is not included. No heading is necessary for this section.

This section consists of a one-line sentence ending in a period that describes the function, class, or method’s effect.

Deprecation warnings should go directly after the Single-Sentence Summary, so as to notify users right away. Deprecation warnings should be written as a deprecated in the Sphinx directive:

```
.. deprecated:: 1.1

 The ``simplify_this`` function is deprecated. Use :func:`simplify`
 instead. See its documentation for more information.
```

See [Documenting a deprecation](#) (page 3022) for more details.

## 2. Explanation Section

This section is encouraged. If you choose to include an Explanation section in your docstring, it should be labeled with the heading “Explanation” underlined with the same length in equals signs.

```
Explanation
=====
```

This section consists of a more elaborate description of what the function, class, or method does when the concise Single-Sentence Summary will not suffice. This section should be used to clarify functionality in several sentences or paragraphs.

## 3. Examples Section

This section is **required** for every docstring. A docstring will not pass review if it is not included. It should be labeled with the heading “Examples” (even if there is only one example) underlined with the same length in equals signs.

```
Examples
=====
```

This section consists of examples that show how the function works, called doctests. Doctests should be complicated enough that they fully demonstrate the API and functionality of the function, but simple enough that a user can understand them without too much thought. The perfect doctest tells the user exactly what they need to know about the function without reading any other part of the docstring.

There should always be a blank line before the doctest. When multiple examples are provided, they should be separated by blank lines. Comments explaining the examples should have blank lines both above and below them.

Do not think of doctests as tests. Think of them as examples that happen to be tested. They should demonstrate the API of the function to the user (i.e., what the input parameters look like, what the output looks like, and what it does). If you only want to test something, add a test to the relevant `test_*.py` file.

You can use the `./bin/coverage_doctest.py` script to test the doctest coverage of a file or module. Run the doctests with `./bin/doctest`.

You should only skip the testing of an example if it is impossible to test it. If necessary, testing of an example can be skipped by adding a special comment.

### Example

```
>>> import random
>>> random.random()
0.6868680200532414
```

If an example is longer than 80 characters, it should be line wrapped. Examples should be line wrapped so that they are still valid Python code, using `...` continuation as in a Python prompt. For example, from the ODE module documentation:

### Example

```
>>> from sympy import Function, dsolve, cos, sin
>>> from sympy.abc import x
>>> f = Function('f')
>>> dsolve(cos(f(x)) - (x*sin(f(x)) - f(x)**2)*f(x).diff(x),
... f(x), hint='1st_exact')
Eq(x*cos(f(x)) + f(x)**3/3, C1)
```

Here `dsolve(cos(f(x)) - (x*sin(f(x)) - f(x)**2)*f(x).diff(x), f(x), hint='1st_exact')` is too long, so we line break it after a comma so that it is readable, and put `...` on the continuation lines. If this is not done correctly, the doctests will fail.

The output of a command can also be line wrapped. No `...` should be used in this case. The doctester automatically accepts output that is line wrapped.

### Example

```
>>> list(range(30))
[0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20,
21, 22, 23, 24, 25, 26, 27, 28, 29]
```

In a doctest, write imports like `sympy import ...` instead of `import sympy` or `from sympy import *`. To define symbols, use `from sympy.abc import x`, unless the name is not in `sympy.abc` (for instance, if it has assumptions), in which case use symbols like `x`, `y = symbols('x y')`.

In general, you should run `./bin/doctest` to make sure your examples run correctly, and fix them if they do not.

## 4. Parameters Section

This section is encouraged. If you choose to include a Parameters section in your docstring, it should be labeled with the heading “Parameters” underlined with the same length in equals signs.

```
Parameters
=====
```

If you have parameters listed in parentheses after a function, class, or method name, you must include a parameters section.

This section consists of descriptions of the function arguments, keywords, and their respective types.

Enclose variables in double backticks. The colon must be preceded by a space, or omitted if the type is absent. For the parameter types, be as precise as possible. If it is not necessary to specify a keyword argument, use `optional`. Optional keyword parameters have default values, which are displayed as part of the function signature. They can also be detailed in the description.

When a parameter can only assume one of a fixed set of values, those values can be listed in braces, with the default appearing first. When two or more input parameters have exactly the same type, shape, and description, they can be combined.

If the Parameters section is not formatted correctly, the documentation build will render incorrectly.

If you wish to include a Returns section, write it as its own section with its own heading.

### Example

Here is an example of a correctly formatted Parameters section:

```
def opt_cse(exprs, order='canonical'):
 """
 Find optimization opportunities in Adds, Muls, Pows and negative
 coefficient Muls.

 Parameters
 =====

 exprs : list of sympy expressions
 The expressions to optimize.
 order : string, 'none' or 'canonical'
 The order by which Mul and Add arguments are processed. For large
 expressions where speed is a concern, use the setting order='none'.

 """
```

## 5. See Also Section

This section is encouraged. If you choose to include a See Also section in your docstring, it should be labeled with the heading “See Also” underlined with the same length in equals signs.

```
See Also
=====
```

This section consists of a listing of related functions, classes, and methods. The related items can be described with a concise fragment (not a full sentence) if desired, but this is not required. If the description spans more than one line, subsequent lines must be indented.

The See Also section should only be used to reference other SymPy objects. Anything that is a link should be embedded as a hyperlink in the text of the docstring instead; see the References section for details.

Do not reference classes with `class:Classname`, `class:`Classname``, or `:class:`Classname``, but rather only by their class name.

### Examples

Here is a correctly formatted See Also section with concise descriptions:

```
class erf(Function):
 r"""
 The Gauss error function.

 See Also
 =====

 erfc: Complementary error function.
 erfi: Imaginary error function.
```

(continues on next page)

(continued from previous page)

```

erf2: Two-argument error function.
erfinv: Inverse error function.
erfcinv: Inverse Complementary error function.
erf2inv: Inverse two-argument error function.

"""

```

Here is a correctly formatted See Also section with just a list of names:

```

class besselj(BesselBase):
 r"""
 Bessel function of the first kind.

 See Also
 =====

 bessely, besseli, bess elk

 """

```

## 6. References Section

This section is encouraged. If you choose to include a References section in your docstring, it should be labeled with the heading “References” underlined with the same length in equals signs.

```

References
=====

```

This section consists of a list of references cited anywhere in the previous sections. Any reference to other SymPy objects should go in the See Also section instead.

The References section should include online resources, paper citations, and/or any other printed resource giving general information about the function. References are meant to augment the docstring, but should not be required to understand it. References are numbered, starting from one, in the order in which they are cited.

For online resources, only link to freely accessible and stable online resources such as Wikipedia, Wolfram MathWorld, and the NIST Digital Library of Mathematical Functions (DLMF), which are unlikely to suffer from hyperlink rot.

References for papers should include, in this order: reference citation, author name, title of work, journal or publication, year published, page number.

If there is a DOI (Digital Object Identifier), include it in the citation and make sure it is a clickable hyperlink.

### Examples

Here is a References section that cites a printed resource:

```

References
=====

```

(continues on next page)

(continued from previous page)

```
.. [1] [Kozen89] D. Kozen, S. Landau, Polynomial Decomposition Algorithms,
 Journal of Symbolic Computation 7 (1989), pp. 445-456
```

Here is a References section that cites printed and online resources:

#### References

```
=====

```

### 6.5.4 Sample Docstring

Here is an example of a correctly formatted docstring:

```
class gamma(Function):
 r"""
 The gamma function

 .. math::
 \Gamma(x) := \int^{\infty}_{0} t^{x-1} e^{-t} \mathrm{d}t.

 Explanation
 =====

 The ``gamma`` function implements the function which passes through the
 values of the factorial function (i.e., $\Gamma(n) = (n - 1)!$), when n
 is an integer. More generally, $\Gamma(z)$ is defined in the whole
 complex plane except at the negative integers where there are simple
 poles.

 Examples
 =====

 >>> from sympy import S, I, pi, oo, gamma
 >>> from sympy.abc import x

 Several special values are known:

 >>> gamma(1)
 1
 >>> gamma(4)
 6
 >>> gamma(S(3)/2)
 sqrt(pi)/2
```

(continues on next page)

(continued from previous page)

The ``gamma`` function obeys the mirror symmetry:

```
>>> from sympy import conjugate
>>> conjugate(gamma(x))
gamma(conjugate(x))
```

Differentiation with respect to  $x$  is supported:

```
>>> from sympy import diff
>>> diff(gamma(x), x)
gamma(x)*polygamma(0, x)
```

Series expansion is also supported:

```
>>> from sympy import series
>>> series(gamma(x), x, 0, 3)
1/x - EulerGamma + x*(EulerGamma**2/2 + pi**2/12) + x**2*(-
→ EulerGamma*pi**2/12 +
polygamma(2, 1)/6 - EulerGamma**3/6) + O(x**3)
```

We can numerically evaluate the ``gamma`` function to arbitrary precision on the whole complex plane:

```
>>> gamma(pi).evalf(40)
2.288037795340032417959588909060233922890
>>> gamma(1+I).evalf(20)
0.49801566811835604271 - 0.15494982830181068512*I
```

See Also

=====

lowergamma: Lower incomplete gamma function.  
 uppgamma: Upper incomplete gamma function.  
 polygamma: Polygamma function.  
 loggamma: Log Gamma function.  
 digamma: Digamma function.  
 trigamma: Trigamma function.  
 beta: Euler Beta function.

"""

### 6.5.5 Docstrings for Classes that are Mathematical Functions

SymPy is unusual in that it also has classes that are mathematical functions. The docstrings for classes that are mathematical functions should include details specific to this kind of class, as noted below:

- The Explanation section should include a mathematical definition of the function. This should use LaTeX math. Use `$$` for *inline math* (page 3013) and `.. math::` for display math, which should be used for the main definition. The variable names in the formulas should match the names of the parameters, and the LaTeX formatting should match the LaTeX pretty printing used by SymPy. As relevant, the mathematical definitions should mention their domain of definition, especially if the domain is different from the complex numbers.
- If there are multiple conventions in the literature for a function, make sure to clearly specify which convention SymPy uses.
- The Explanation section may also include some important mathematical facts about the function. These can alternately be demonstrated in the Examples section. Mathematical discussions should not be too long, as users can check the references for more details.
- The docstring does not need to discuss every implementation detail such as at which operations are defined on the function or at which points it evaluates in the “eval” method. Important or illuminating instances of these can be shown in the Examples section.
- The docstring should go on the class level (right under the line that has “class”). The “eval” method should not have a docstring.
- Private methods on the class, that is, any method that starts with an underscore, do not need to be documented. They can still be documented if you like, but note that these docstrings are not pulled into the Sphinx documentation, so they will only be seen by developers who are reading the code, so if there is anything very important that you want to mention here, it should go in the class-level docstring as well.

### 6.5.6 Best Practices for Writing Docstrings

When writing docstrings, please follow all of the same formatting, style, and tone preferences as when writing narrative documentation. For guidelines, see [Best Practices for Writing Documentation](#) (page 3013), Formatting, Style, and Tone.

### 6.5.7 Importing Docstrings into the Sphinx Documentation

Here are excerpts from the `doc/src/modules/geometry` directory that imports the relevant docstrings from geometry module into documentation:

```
Utils
=====

.. module:: sympy.geometry.util

.. autofunction:: intersection

.. autofunction:: convex_hull
```

(continues on next page)

(continued from previous page)

```
.. autofunction:: are_similar

Points
=====

.. module:: sympy.geometry.point

.. autoclass:: Point
 :members:

Lines
=====

.. module:: sympy.geometry.line

.. autoclass:: LinearEntity
 :members:

.. autoclass:: Line
 :members:

.. autoclass:: Ray
 :members:

.. autoclass:: Segment
 :members:

Curves
=====

.. module:: sympy.geometry.curve

.. autoclass:: Curve
 :members:

Ellipses
=====

.. module:: sympy.geometry.ellipse

.. autoclass:: Ellipse
 :members:

.. autoclass:: Circle
 :members:

Polygons
=====

.. module:: sympy.geometry.polygon

.. autoclass:: Polygon
```

(continues on next page)

(continued from previous page)

```
:members:

.. autoclass:: RegularPolygon
 :members:

.. autoclass:: Triangle
 :members:
```

First namespace is set to particular submodule (file) with `.. module::` directive, then docstrings are imported with `.. autoclass::` or `.. autofunction::` relative to that submodule (file). Other methods are either cumbersome to use (using full paths for all objects) or break something (importing relative to main module using `.. module:: sympy.geometry` breaks viewcode Sphinx extension). All files in `doc/src/modules/` should use this format.

### 6.5.8 Cross-Referencing

Any text that references another SymPy function should be formatted so that a cross-reference link to that function’s documentation is created automatically. This is done using the RST cross-reference syntax. There are two different kinds of objects that have conventions here:

1. Objects that are included in `from sympy import *`, for example, `sympy.acos`.

For these, use `:obj:`~.acos()``. The `~` makes it so that the text in the rendered HTML only shows `acos` instead of the fully qualified name `sympy.functions.elementary.trigonometric.acos`. (This will encourage importing names from the global `sympy` namespace instead of a specific submodule.) The `.` makes it so that the function name is found automatically. (If Sphinx gives a warning that there are multiple names found, replace the `.` with the full name. For example, `:obj:`~sympy.solvers.solvers.solve()``.) Adding a trailing pair of parentheses is a convention for indicating the name is a function, method, or class.

You may also use a more specific type indicator instead of `obj` (see <https://www.sphinx-doc.org/en/master/usage/restructuredtext/domains.html#cross-referencing-python-objects>).

However, `obj` will always work, and sometimes SymPy names are not the type you might expect them to be. For example, mathematical function objects such as `sin` are not actually a Python function, rather they are a Python class, therefore `:func:`~.sin`` will not work.

2. Objects that are not included in `from sympy import *`, for example, `sympy.physics.vector.dynamicsymbols`.

This can be public API objects from submodules that are not included in the main `sympy/__init__.py`, such as the `physics` submodule, or private API objects that are not necessarily intended to be used by end-users (but should still be documented). In this case, you must show the fully qualified name, so do not use the `~.` syntax. For example, `:obj:`~sympy.physics.vector.dynamicsymbols()``.

You may also write custom text that links to the documentation for something using the following syntax `:obj:`custom text<object>``. For example, `:obj:`the sine function <.sin>`` produces the text “the sine function” that links to the documentation for `sin`. Note that the `~` character should not be used here.

Note that references in the *See Also* (page 3002) section of the docstrings do not require the `:obj:` syntax.

If the resulting cross reference is written incorrectly, Sphinx will error when building the docs with an error like:

WARNING: py:obj reference target **not** found: expand

Here are some troubleshooting tips to fix the errors:

- Make sure you have used the correct syntax, as described above.
- Make sure you spelled the function name correctly.
- Check if the function you are trying to cross-reference is actually included in the Sphinx documentation. If it is not, Sphinx will not be able to create a reference for it. In that case, you should add it to the appropriate RST file as described in the [Docstring Guidelines](#) (page 2997).
- If the function or object is not included in `from sympy import *`, you will need to use the fully qualified name, like `sympy.submodule.submodule.function` instead of just `function`.
- A fully qualified name must include the full submodule for a function all the way down to the file. For example, `sympy.physics.vector.ReferenceFrame` will not work (even though you can access it that way in code). It has to be `sympy.physics.vector.frame.ReferenceFrame`.
- If the thing you are referring to does not actually have somewhere to link to, do not use the `:obj:` syntax. Instead, mark it as code using double backticks. Examples of things that cannot be linked to are Python built in functions like `int` or `NotImplementedError`, functions from other modules outside of SymPy like `matplotlib.plot`, and variable or parameter names that are specific to the text at hand. In general, if the object cannot be accessed as `sympy.something.something.object`, it cannot be cross- referenced and you should not use the `:obj:` syntax.
- If you are using one of the [type specific](#) identifiers like `:func:`, be sure that the type for it is correct. `:func:` only refers to Python functions. For classes, you need to use `:class:`, and for methods on a class you need to use `:method:`. In general, it is recommended to use `:obj:`, as this will work for any type of object.
- If you cannot get the cross-referencing syntax to work, go ahead and submit the pull request as is and ask the reviewers for help.

You may also see errors like:

WARNING: more than one target found **for** cross-reference `'subs()'`:  
`sympy.core.basic.Basic.subs`, `sympy.matrices.common.MatrixCommon.subs`,  
`sympy.physics.vector.vector.Vector.subs`,  
`sympy.physics.vector.dyadic.Dyadic.subs`

for instance, from using `:obj:`~.subs``. This means that the `.` is not sufficient to find the function, because there are multiple names in SymPy named `subs`. In this case, you need to use the fully qualified name. You can still use `~` to make it shortened in the final text, like `:obj:`~~sympy.core.basic.Basic.subs``.

The line numbers for warnings in Python files are relative to the top of the docstring, not the file itself. The line numbers are often not completely correct, so you will generally have to search the docstring for the part that the warning is referring to. This is due to a bug in Sphinx.

## 6.6 Documentation Style Guide

### 6.6.1 General Guidelines

Documentation is one of the most highly valued aspects of an open source project. Documentation teaches users and contributors how to use a project, how to contribute, and the standards of conduct within an open source community. But according to GitHub's [Open Source Survey](#), incomplete or confusing documentation is the most commonly encountered problem in open source. This style guide aims to change that.

The purpose of this style guide is to provide the SymPy community with a set of style and formatting guidelines that can be utilized and followed when writing SymPy documentation. Adhering to the guidelines offered in this style guide will bring greater consistency and clarity to SymPy's documentation, supporting its mission to become a full-featured, open source computer algebra system (CAS).

The SymPy documentation found at [docs.sympy.org](https://docs.sympy.org) is generated from docstrings in the source code and dedicated narrative documentation files in the `doc/src` directory. Both are written in `reStructuredText` format extended by `Sphinx`.

The documentation contained in the `doc/src` directory and the docstrings embedded in the Python source code are processed by Sphinx and various Sphinx extensions. This means that the documentation source format is specified by the documentation processing tools. The SymPy Documentation Style Guide provides both the essential elements for writing SymPy documentation as well as any deviations in style we specify relative to these documentation processing tools. The following lists the processing tools:

- `reStructuredText`: Narrative documentation files and documentation strings embedded in Python code follow the `reStructuredText` format. Advanced features not described in this document can be found at <http://docutils.sourceforge.net/rst.html>.
- `Sphinx`: Sphinx includes additional default features for the `reStructuredText` specification that are described at: <http://www.sphinx-doc.org/>.
- Sphinx extensions included with Sphinx that we enable:
  - `sphinx.ext.autodoc`: Processes Python source code files for the associated documentation strings to automatically generate pages containing the Application Programming Interface (API). See section on calling autodoc directives in this document to get started. More information is at: <https://www.sphinx-doc.org/en/master/usage/extensions/autodoc.html>.
  - `sphinx.ext.graphviz`: Provides a directive for adding Graphviz graphics. See <https://www.sphinx-doc.org/en/master/usage/extensions/graphviz.html> for more info.
  - `sphinx.ext.mathjax`: Causes math written in LaTeX to display using MathJax in the HTML version of the documentation. More information is at: <https://www.sphinx-doc.org/en/master/usage/extensions/math.html#module-sphinx.ext.mathjax>. *No bearing on documentation source format.*
  - `sphinx.ext.linkcode`: Causes links to source code to direct to the related files on Github. More information is at: <https://www.sphinx-doc.org/en/master/usage/extensions/linkcode.html>. *No bearing on documentation source format.*
- Sphinx extensions that are not included with Sphinx that we enable:

- `numpydoc`: Processes docstrings written in the “numpydoc” format, see <https://numpydoc.readthedocs.io>. We recommend the subset of numpydoc formatting features in this document. (Note that we currently use an older modified fork of numpydoc, which is included in the SymPy source code.)
- `sphinx_math_dollar`: Allows math to be delimited with dollar signs instead of reStructuredText directives (e.g.,  $a^2$  instead of `:math:`a^2``). See <https://www.sympy.org/sphinx-math-dollar/> for more info.
- `matplotlib.sphinxext.plot_directive`: Provides directives for included matplotlib generated figures in reStructuredText. See [https://matplotlib.org/devel/plot\\_directive.html](https://matplotlib.org/devel/plot_directive.html) for more info.

Everything supported by the above processing tools is available for use in the SymPy documentation, but this style guide supersedes any recommendations made in the above documents. Note that we do not follow PEP 257 or the [www.python.org](http://www.python.org) documentation recommendations.

If you are contributing to SymPy for the first time, please read our [Introduction to Contributing](#) page as well as this guide.

## 6.6.2 Types of Documentation

There are four main locations where SymPy’s documentation can be found:

**SymPy Website** <https://sympy.org>

The SymPy website’s primary function is to advertise the software to users and developers. It also serves as an initial location to point viewers to other relevant resources on the web. The SymPy website has basic information on SymPy and how to obtain it, as well as examples to advertise it to users, but it does not have technical documentation. The source files are located in the SymPy [webpage directory](#). Appropriate items for the website are:

- General descriptions of what SymPy and the SymPy community are
- Explanations/demonstrations of major software features
- Listings of other major software that uses SymPy
- Getting started info for users (download and install instructions)
- Getting started info for developers
- Where users can get help and support on using SymPy
- News about SymPy

**SymPy Documentation** <https://docs.sympy.org>

This is the main place where users go to learn how to use SymPy. It contains a tutorial for SymPy as well as technical documentation for all of the modules. The source files are hosted in the main SymPy repository in the [doc directory](#) at and are built using the [Sphinx site generator](#) and uploaded to the [docs.sympy.org](https://docs.sympy.org) site automatically. There are two primary types of pages that are generated from different source files in the docs directory:

- **Narrative Pages**: reStructuredText files that correspond to manually written documentation pages not present in the Python source code. Examples are the [tutorial RST files](#). In general, if your documentation is not API documentation it belongs in a narrative page.

- API Documentation Pages: reStructuredText files that contain directives that generate the Application Programming Interface documentation. These are automatically generated from the SymPy Python source code.

### SymPy Source Code <https://github.com/sympy/sympy>

Most functions and classes have documentation written inside it in the form of a docstring, which explains the function and includes examples called doctests. The purpose of these docstrings are to explain the API of that class or function. The doctests examples are tested as part of the test suite, so that we know that they always produce the output that they say that they do. Here is an [example docstring](#). Most docstrings are also automatically included in the Sphinx documentation above, so that they appear on the SymPy Documentation website. Here is that [same docstring](#) (page 383) on the SymPy website. The docstrings are formatted in a specific way so that Sphinx can render them correctly for the docs website. The SymPy sources all contain sparse technical documentation in the form of source code comments, although this does not generally constitute anything substantial and is not displayed on the documentation website.

### SymPy Wiki <https://github.com/sympy/sympy/wiki>

The SymPy Wiki can be edited by anyone without review. It contains various types of documentation, including:

- High-level developer documentation (for example: <https://github.com/sympy/sympy/wiki/Args-Invariant>)
- Guides for new contributors (for example: <https://github.com/sympy/sympy/wiki/Introduction-to-contributing>)
- Development policies (for example: <https://github.com/sympy/sympy/wiki/Python-version-support-policy>)
- Release notes (for example: <https://github.com/sympy/sympy/wiki/Release-Notes-for-1.5>)
- Various pages that different contributors have added

## 6.6.3 Narrative Documentation Guidelines

Extensive documentation, or documentation that is not centered around an API reference, should be written as a narrative document in the Sphinx docs (located in the [doc/src directory](#)). The narrative documents do not reside in the Python source files, but as standalone restructured files in the doc/src directory. SymPy's narrative documentation is defined as the collective documents, tutorials, and guides that teach users how to use SymPy. Reference documentation should go in the docstrings and be pulled into the RST with autodoc. The RST itself should only have narrative style documentation that is not a reference for a single specific function.

### 6.6.4 Documentation using Markdown

Narrative documentation can be written using either Restructured Text (`.rst`) or Markdown (`.md`). Markdown documentation uses [MyST](#). See [this guide](#) for more information on how to write documents in Markdown. Markdown is only supported for narrative documentation. Docstrings should continue to use RST syntax. Any part of this style guide that is not specific to RST syntax should still apply to Markdown documents.

### 6.6.5 Best Practices for Writing Documentation

Please follow these formatting, style, and tone preferences when writing documentation.

#### Formatting Preferences

In order for math and code to render correctly on the SymPy website, please follow these formatting guidelines.

#### Math

Text that is surrounded by dollar signs `$ _ $` will be rendered as LaTeX math. Any text that is meant to appear as LaTeX math should be written as `$math$`. In the HTML version of the docs, MathJax will render the math.

#### Example

The Bessel  $J_\nu$  function of order  $\nu$  is defined to be the function satisfying Bessel's differential equation.

#### LaTeX Recommendations

- If a docstring has any LaTeX, be sure to make it “raw.” See the [Docstring Formatting](#) (page 2998) section for details.
- If you are not sure how to render something, you can use the SymPy [`latex\(\)`](#) (page 2170) function. But be sure to strip out the unimportant parts (the bullet points below).
- Avoid unnecessary `\left` and `\right` (but be sure to use them when they are required).
- Avoid unnecessary `{}`. (For example, write `x^2` instead of `x^{2}`.)
- Use whitespace in a way that makes the equation easiest to read.
- Always check the final rendering to make sure it looks the way you expect it to.
- The HTML documentation build will not fail if there is invalid math, but rather it will show as an error on the page. However, the PDF build, which is run on GitHub Actions on pull requests, will fail. If the LaTeX PDF build fails on CI, there is likely an issue with LaTeX math somewhere.

#### Examples

Correct:

```
\int \sin(x)\,dx
```

Incorrect:

```
\int \sin{\left(x\right)}\, dx
```

For more in-depth resources on how to write math in LaTeX, see:

- <https://math.meta.stackexchange.com/questions/5020/mathjax-basic-tutorial-and-quick-reference>
- <https://en.wikibooks.org/wiki/LaTeX/Mathematics>
- [https://www.overleaf.com/learn/latex/Mathematical\\_expressions](https://www.overleaf.com/learn/latex/Mathematical_expressions)

## Code

Text that should be printed verbatim, such as code, should be surrounded by a set of double backticks like this.

### Example

```
To use this class, define the ``_rewrite()`` and ``_expand()`` methods.
```

Sometimes a variable will be the same in both math and code, and can even appear in the same paragraph, making it difficult to know if it should be formatted as math or code. If the sentence in question is discussing mathematics, then LaTeX should be used, but if the sentence is discussing the SymPy implementation specifically, then code should be used.

In general, the rule of thumb is to consider if the variable in question were something that rendered differently in code and in math. For example, the Greek letter  $\alpha$  would be written as `alpha` in code and  `$\alpha$`  in LaTeX. The reason being that  `$\alpha$`  cannot be used in contexts referring to Python code because it is not valid Python, and conversely `alpha` would be incorrect in a math context because it does not render as the Greek letter ( $\alpha$ ).

### Example

```
class loggamma(Function):
 r"""
 The ``loggamma`` function implements the logarithm of the gamma
 function (i.e., $\log\Gamma(x)$).

 """
```

Variables listed in the parameters after the function name should, in written text, be italicized using Sphinx emphasis with asterisks like `*this*`.

### Example

```
def stirling(n, k, d=None, kind=2, signed=False):
 """
 ...

 The first kind of Stirling number counts the number of permutations of
 n distinct items that have *k* cycles; the second kind counts the
 ways in which *n* distinct items can be partitioned into *k* parts.
 If *d* is given, the "reduced Stirling number of the second kind" is
```

(continues on next page)

(continued from previous page)

```

returned: $S^{\{d\}}(n, k) = S(n - d + 1, k - d + 1)$ with $n \geq k \geq d$.
This counts the ways to partition n consecutive integers into k
groups with no pairwise difference less than d .

```

```

"""

```

Note that in the above example, the first instances of  $n$  and  $k$  are referring to the input parameters of the function `stirling`. Because they are Python variables but also parameters listed by themselves, they are formatted as parameters in italics. The last instances of  $n$  and  $k$  are talking about mathematical expressions, so they are formatted as math.

If a variable is code, but is also a parameter written by itself, the parameter formatting takes precedence and it should be rendered in italics. However, if a parameter appears in a larger code expression it should be within double backticks to be rendered as code. If a variable is only code and not a parameter as well, it should be in double backticks to be rendered as code.

Please note that references to other functions in SymPy are handled differently from parameters or code. If something is referencing another function in SymPy, the cross-reference reStructuredText syntax should be used. See the section on [Cross-Referencing](#) (page 3008) for more information.

## Headings

Section headings in reStructuredText files are created by underlining (and optionally overlining) the section title with a punctuation character at least as long as the text.

Normally, there are no heading levels assigned to certain characters as the structure is determined from the succession of headings. However, for SymPy's documentation, here is a suggested convention:

```

=== with overline: title (top level heading)

```

```

=== heading 1

```

```

- - - heading 2

```

```

^^^ heading 3

```

```

~~~ heading 4

```

```

""" heading 5

```

## Style Preferences

### Spelling and Punctuation

All narrative writing in SymPy follows American spelling and punctuation standards. For example, "color" is preferred over "colour" and commas should be placed inside of quotation marks.

### Examples

If the ``line\_color`` aesthetic is a function of arity 1, then the coloring is a function of the x value of a point.

The term "unrestricted necklace," or "bracelet," is used to imply an object that can be turned over or a sequence that can be reversed.

If there is any ambiguity about the spelling of a word, such as in the case of a function named after a person, refer to the spelling of the actual SymPy function.

For example, Chebyshev polynomials are named after Pafnuty Lvovich Tchebychev, whose name is sometimes transliterated from Russian to be spelled with a "T," but in SymPy it should always be spelled "Chebyshev" to refer to the SymPy function.

### Example

```
class chebyshevt(OrthogonalPolynomial):
    r"""
    Chebyshev polynomial of the first kind,  $T_n(x)$ 
    ...
    """
```

## Capitalization

Title case capitalization is preferred in all SymPy headings.

### Example

```
What is Symbolic Computation?
-----
```

## Tone Preferences

Across SymPy documentation, please write in:

- The present tense (e.g., In the following section, we are going to learn...)
- The first-person inclusive plural (e.g., We did this the long way, but now we can try it the short way...)
- Use the generic pronoun "you" instead of "one." Or use "the reader" or "the user." (e.g., You can access this function by... The user can then access this function by...)
- Use the gender-neutral pronoun "they" instead of "he" or "she." (e.g., A good docstring tells the user exactly what they need to know.)

Avoid extraneous or belittling words such as "obviously," "easily," "simply," "just," or "straightforward."

Avoid unwelcoming or judgement-based phrases like "That is wrong." Instead use friendly and inclusive language like "A common mistake is..."

Avoid extraneous phrases like, "we just have to do one more thing."

## 6.7 Making a Contribution

For in-depth instructions on how to contribute to SymPy's code base including coding conventions, creating your environment, picking an issue to fix, and opening a pull request, please read our full [Development Workflow](#) guide.

## 6.8 Deprecation Policy

This page outlines SymPy's policy on doing deprecations, and describes the steps developers should take to properly deprecate code.

A list of all currently active deprecations in SymPy can be found at [List of active deprecations](#) (page 163).

### 6.8.1 What is a deprecation?

A deprecation is a way to make backwards incompatible changes in a way that allows users to update their code. Deprecated code continues to work as it used to, but whenever someone uses it, it prints a warning to the screen indicating that it will be removed in a future version of SymPy, and indicating what the user should be using instead.

This allows users a chance to update their code without it completely breaking. It also gives SymPy an opportunity to give users an informative message on how to update their code, rather than making their code simply error or start giving wrong answers.

### 6.8.2 Try to avoid backwards incompatible changes in the first place

Backwards incompatible API changes should not be made lightly. Any backwards compatibility break means that users will need to fix their code. Whenever you want to make a breaking change, you should consider whether this is worth the pain for users. Users who have to update their code to match new APIs with every SymPy release will become frustrated with the library, and may go seek a more stable alternative. Consider whether the behavior you want can be done in a way that is compatible with existing APIs. New APIs do not necessarily need to completely supplant old ones. It is sometimes possible for old APIs to exist alongside newer, better designed ones without removing them. For example, the newer [`solveset`](#) (page 858) API was designed to be a superior replacement for the older [`solve`](#) (page 836) API. But the older `solve()` function remains intact and is still supported.

It is important to try to be cognizant of API design whenever adding new functionality. Try to consider what a function may do in the future, and design the API in a way that it can do so without having to make a breaking change. For example, if you add a property to an object `A.attr`, it is impossible to later convert that property into a method `A.attr()` so that it can take arguments, except by doing so in a backwards incompatible way. If you are unsure about your API design for a new functionality, one option is to mark the new functionality as explicitly private or as experimental.

With that being said, it may be decided that the API of SymPy must change in some incompatible way. Some reasons APIs are changed can include:

- The existing API is confusing.

- There is unnecessary redundancy in the API.
- The existing API limits what is possible.

Because one of the core use-cases of SymPy is to be usable as a library, we take API breakage very seriously. Whenever an API breakage is necessary, the following steps should be taken:

- Discuss the API change with the community. Be sure that the improved API is indeed better, and worth a breakage. It is important to get API right so that we will not need to break the API again to “fix” it a second time.
- If it is possible, deprecate the old API. The technical steps for doing this are described [below](#) (page 3020).
- Document the change so that users know how to update their code. The documentation that should added is described [below](#) (page 3022).

### 6.8.3 When does a change require deprecation?

When considering whether a change requires a deprecation, two things must be considered:

- Is the change backwards incompatible?
- Is the behavior changing public API?

A change is backwards incompatible if user code making use of it would stop working after the change.

What counts as “public API” needs to be considered on a case-by-case basis. The exact rules for what does and doesn’t constitute public API for SymPy are still not yet fully codified. Cleaning up the distinction between public and private APIs, as well as the categorization in the reference documentation is currently an [open issue for SymPy](#).

Here are some thing that constitute public API. *Note: these are just general guidelines. This list is not exhaustive, and there are always exceptions to the rules.*

---

#### Public API

- Function names.
  - Keyword argument names.
  - Keyword argument default values.
  - Positional argument order.
  - Submodule names.
  - The mathematical conventions used to define a function.
- 

And here are some things that generally aren’t public API, and therefore don’t require deprecations to change (again, this list is only a general set of guidelines).

---

#### Not Public API

- The precise form of an expression. In general, functions may be changed to return a different but mathematically equivalent form of the same expression. This includes a function returning a value which it was not able to compute previously.

- Functions and methods that are private, i.e., for internal use only. Such things should generally be prefixed with an underscore `_`, although this convention is not currently universally adhered to in the SymPy codebase.
- Anything explicitly marked as “experimental”.
- Changes to behavior that were mathematically incorrect previously (in general, bug fixes are not considered breaking changes, because despite the saying, bugs in SymPy are not features).
- Anything that was added before the most recent release. Code that has not yet made it into a release does not need to be deprecated. If you are going to change the API of new code, it is best to do it before a release is made so that no deprecations are necessary for future releases.

---

Note: both public and private API functions are included in the [reference documentation](#) (page 185), and many functions are not included there which should be, or are not documented at all which should be, so this should not be used to determine whether something public or not.

If you’re unsure, there is no harm in deprecating something even if it might not actually be “public API”.

### 6.8.4 The purpose of deprecation

Deprecation has several purposes:

- To allow existing code to continue to work for a while, giving people a chance to upgrade SymPy without fixing all deprecation issues immediately.
- To warn users that their code will break in a future version.
- To inform users how to fix their code so that it will continue work in future versions.

All deprecation warnings should be something that users can remove by updating their code. Deprecation warnings that fire unconditionally, even when using the “correct” newer APIs, should be avoided.

This also means all deprecated code must have a completely functioning replacement. If there is no way for users to update their code, then this means API in question is not yet ready to be deprecated. The deprecation warning should inform users of a way to change their code so that it works in the same version of SymPy, as well as all future versions, and, if possible, previous versions of SymPy as well. See [below](#) (page 3022).

Deprecations should always

1. Allow users to continue to use the existing APIs unchanged during the deprecation period (with a warning, which can be [silenced](#) (page 164) with `warnings.filterwarnings`).
2. Allow users to always fix their code so that it stops giving the warning.
3. After users fix their code, it should continue to work after the deprecated code is removed.

The third point is important. We do not want the “new” method to itself cause another API break when the deprecation period is over. Doing this would completely defeat the purpose of doing a deprecation.

### When it is not technically possible to deprecate

In some cases, this is not technically possible to make a deprecation that follows the above three rules. API changes of this nature should be considered the most heavily, as they will break people's code immediately without warning. Consideration into how easy it will be for users to support multiple versions of SymPy, one with the change and one without, should also be taken into account.

If you decide that the change is nonetheless worth making, there are two options:

- Make the non-deprecatable change immediately, with no warnings. This will break user code.
- Warn that the code will change in the future. There won't be a way for users to fix their code until a version is released with the breaking change, but they will at least be aware that changes are coming.

Which of the two to make should be decided on a case-by-case basis.

### 6.8.5 How long should deprecations last?

Deprecations should remain intact for **at least 1 year** after the first major release is made with the deprecation. This is only a minimum period: deprecations are allowed to remain intact for longer than this. If a change is especially hard for users to migrate, the deprecation period should be lengthened. The period may also be lengthened for deprecated features that do not impose a significant maintenance burden to keep around.

The deprecation period policy is time-based rather than release-based for a few reasons. Firstly, SymPy does not have a regular release schedule. Sometimes multiple releases will be made in a year, and some years only a single release will be made. Being time-based assures that users have sufficient opportunity to update their code regardless of how often releases happen to be made.

Secondly, SymPy does not make use of a rigorous versioning scheme like semantic versioning. The API surface of SymPy and number of contributions are both large enough that virtually every major release has some deprecations and backwards incompatible changes made in some submodule. Encoding this into the version number would be virtually impossible. The development team also does not backport changes to prior major releases, except in extreme cases. Thus a time-based deprecation scheme is more accurate to SymPy's releasing model than a version-based one would be.

Finally, a time-based scheme removes any temptation to "fudge" a deprecation period down by releasing early. The best way for the developers to accelerate the removal of deprecated functionality is to make a release containing the deprecation as early as possible.

### 6.8.6 How to deprecate code

#### Checklist

Here is a checklist for doing a deprecation. See below for details on each step.

Discuss the backwards incompatible change with the community. Ensure the change is really worth making as per the discussion above.

Remove all instance of the deprecated code from everywhere in the codebase (including doctest examples).

Add `sympy_deprecation_warning()` (page 2067) to the code.

Write a descriptive message for the `sympy_deprecation_warning()` (page 2067). Make sure the message explains both what is deprecated and what to replace it with. The message may be a multiline string and contain examples.

Set `deprecated_since_version` to the version in `sympy/release.py` (without the `.dev`).

Set `active_deprecations_target` to the target used in the `active-deprecations.md` file.

Make sure `stacklevel` is set to the right value so that the deprecation warning shows the user line of code.

Visually confirm the deprecation warning looks good in the console.

Add a `.. deprecated:: <version>` note to the top of the relevant docstring(s).

Add a section to the `doc/src/explanation/active-deprecations.md` file.

Add a cross-reference target (`deprecation-xyz`)= before the section header (this is the same reference used by `active_deprecations_target` above).

Explain what is deprecated and what to replace it with.

Explain *why* the given thing is deprecated.

Add a test using `warns_deprecated_sympy()` (page 2029) that tests that the deprecation warning is issued properly. This test should be the only place in the code that actually uses the deprecated functionality.

Run the test suite to ensure the above test works and that no other code uses the deprecated code, which will cause the tests to fail.

In your PR, add a **BREAKING CHANGE** entry to the release notes for the deprecation.

Once the PR is merged, manually add the change to the “Backwards compatibility breaks and deprecations” section of the release notes on the wiki.

## Adding the deprecation to the code

All deprecations should use `sympy.utilities.exceptions.sympy_deprecation_warning()` (page 2067). If an entire function or method is deprecated, you can use the `sympy.utilities.decorator.deprecated()` (page 2057) decorator. The `deprecated_since_version` and `active_deprecations_target` flags are required. Do not use the `SymPyDeprecationWarning` class directly to issue a deprecation warning. Please see the docstring of `sympy_deprecation_warning()` (page 2067) for more information. See *below* (page 3022) for an example.

Add a test for the deprecated behavior. Use the `sympy.testing.pytest.warns_deprecated_sympy()` (page 2029) context manager.

```
from sympy.testing.pytest import warns_deprecated_sympy

with warns_deprecated_sympy():
    <deprecated behavior>
```

---

**Note:** `warns_deprecated_sympy` is only intended to be used internally by the SymPy test suite. Users of SymPy should use the `warnings` module directly to filter SymPy deprecation warnings. See *Silencing SymPy Deprecation Warnings* (page 164).

---

This has two purposes: to test that the warning is emitted correctly, and to test that the deprecated behavior still actually functions.

If you want to test multiple things and assert that each emits a warning then use separate with blocks for each:

```
with warns_deprecated_sympy():  
    <deprecated behavior1>  
with warns_deprecated_sympy():  
    <deprecated behavior2>
```

This should be the only part of the codebase and test suite that uses the deprecated behavior. Everything else should be changed to use the new, non-deprecated behavior. The SymPy test suite is configured to fail if a `SymPyDeprecationWarning` is issued anywhere except in a `warns_deprecated_sympy()` block. You should not use this function or a `warnings.filterwarnings(SymPyDeprecationWarning)` anywhere except in the test for the deprecation. This includes the documentation examples. The documentation for a deprecated function should just have a note pointing to the non-deprecated alternative. If you want to show a deprecated function in a doctest use `# doctest: +SKIP`. The only exception to this rule is that you may use `ignore_warnings(SymPyDeprecationWarning)` to prevent the exact same warning from triggering twice, i.e., if a deprecated function calls another function that issues the same or a similar warning.

If it is not possible to remove the deprecated behavior somewhere, that is a sign that it is not ready to be deprecated yet. Consider that users may not be able to replace the deprecated behavior for exact same reason.

## Documenting a deprecation

All deprecations should be documented. Every deprecation needs to be documented in three primary places:

- The `sympy_deprecation_warning()` (page 2067) warning text. This text is allowed to be long enough to describe the deprecation, but it should not be more than one paragraph. The primary purpose of the warning text should be *to inform users how to update their code*. The warning text should *not* discuss why a feature was deprecated or unnecessary internal technical details. This discussion can go in the other sections mentioned below. Do not include information in the message that is already part of the metadata provided to the keyword arguments to `sympy_deprecation_warning()`, like the version number or a link to the active deprecations document. Remember that the warning text will be shown in plain-text, so do not use RST or Markdown markup in the text. Code blocks should be clearly delineated with newlines so that they are easy to read. All text in the warning message should be wrapped to 80 characters, except for code examples that cannot be wrapped.

Always include full context of what is deprecated in the message. For example, write “the `abc` keyword to `func()` is deprecated” instead of just “the `abc` keyword is deprecated”. That way if a user has a larger line of code that is using the deprecated functionality, it will be easier for them to see exactly which part is causing the warning.

- A deprecation note in the relevant docstring(s). This should use the `deprecated` Sphinx directive. This uses the syntax `.. deprecated:: <version>`. If the entire function is deprecated, this should be placed at the top of the docstring, right below the first line. Otherwise, if only part of a function is deprecated (e.g., a single keyword argument), it should be placed near the part of the docstring that discusses that feature, e.g., in the parameters list.

The text in the deprecation should be short (no more than a paragraph), explaining what is deprecated and what users should use instead. If you want, you may use the same text here as in the `sympy_deprecation_warning()` (page 2067). Be sure to use RST formatting, including cross-references to the new function if relevant, and a cross-reference to the longer description in the `active-deprecations.md` document (see [below](#) (page 3024)).

If the documentation for the feature is otherwise the same as the replaced feature (i.e., the deprecation is just a renaming of a function or argument), you may replace the rest of the documentation with a note like “see the documentation for <new feature>”. Otherwise, the documentation for the deprecated functionality should be left intact.

Here are some (imaginary) examples:

```
@deprecated("""\
The simplify_this(expr) function is deprecated. Use simplify(expr)
instead.""", deprecated_since_version="1.1",
active_deprecations_target='simplify-this-deprecation')
def simplify_this(expr):
    """
    Simplify ``expr``.

    .. deprecated:: 1.1

    The ``simplify_this`` function is deprecated. Use :func:`simplify`
    instead. See its documentation for more information. See
    :ref:`simplify-this-deprecation` for details.

    """
    return simplify(expr)
```

```
def is_this_zero(x, y=0):
    """
    Determine if  $x = 0$ .

    Parameters
    =====

    x : Expr
        The expression to check.

    y : Expr, optional
        If provided, check if  $x = y$ .

    .. deprecated:: 1.1

    The ``y`` argument to ``is_this_zero`` is deprecated. Use
    ``is_this_zero(x - y)`` instead. See
    :ref:`is-this-zero-y-deprecated` for more details.

    """
    if y != 0:
        sympy_deprecation_warning("""\
The y argument to is_zero() is deprecated. Use is_zero(x - y) instead.""")
```

(continues on next page)

(continued from previous page)

```

→",
        deprecated_since_version="1.1",
        active_deprecations_target='is-this-zero-y-deprecation')
    return simplify(x - y) == 0

```

- A longer description of the deprecation should be added to *the page listing all currently active deprecations* (page 163) in the documentation (in `doc/src/explanation/active-deprecations.md`).

This page is where you can go into more detail about the technical details of a deprecation. Here you should also list *why* a feature was deprecated. You may link to relevant issues, pull requests, and mailing list discussions about the deprecation, but these discussion should be summarized so that users can get the basic idea of why the deprecation without having to read through pages of old discussions. You may also give longer examples here that would not fit in the `sympy_deprecation_warning()` (page 2067) message or `.. deprecated::` text.

Every deprecation should have a cross-reference target (using `(target-name)=` above the section header) so that the `.. deprecated::` note in the relevant docstring can refer to it. This target should also be passed to the `active_deprecations_target` option of `sympy_deprecation_warning()` (page 2067) or `@deprecated` (page 2057). This will automatically put a link to the page in the documentation in the warning message. The target name should include the word “deprecation” or “deprecated” (target names are global in Sphinx, so the target name needs to be unique across the entire documentation).

The section header name should be the thing that is deprecated, and should be a level 3 header under the corresponding version (typically it should be added to the top of the file).

If multiple deprecations are related to one another, they can all share a single section on this page.

If the deprecated function is not included in the top-level `sympy/__init__.py` be sure to clearly indicate which submodule the object is referring to. If you refer to anything that is documented in the Sphinx module reference, cross-reference it, like `{func}~.func_name``.

Note that examples here are helpful, but you generally should not use doctests to show the deprecated functionality, as this will itself raise the deprecation warning and fail the doctest. Instead you may use `# doctest: +SKIP`, or just show the example as a code block instead of a doctest.

Here are examples corresponding to the (imaginary) examples above:

```

(simplify-this-deprecation)=
### `simplify_this()`

The `sympy.simplify.simplify_this()` function is deprecated. It has been
replaced with the {func}~.simplify` function. Code using `simplify_
→this()`
can be fixed by replacing `simplfiy_this(expr)` with `simplify(expr)`.
→The
behavior of the two functions is otherwise identical.

This change was made because `simplify` is a much more Pythonic name than
`simplify_this`.

```

```
(is-this-zero-y-deprecation)=
### `is_this_zero()` second argument
The second argument to {func}~.is_this_zero() is deprecated. Previously
`is_this_zero(x, y)` would check if  $x = y$ . However, this was removed
→ because
it is trivially equivalent to `is_this_zero(x - y)`. Furthermore,
→ allowing
to check  $x=y$  in addition to just  $x=0$  is confusing given the
→ function
is named "is this zero".
```

In particular, replace

```
```py
is_this_zero(expr1, expr2)
```
```

with

```
```py
is_this_zero(expr1 - expr2)
```
```

In addition to the above examples, there are dozens of examples of existing deprecations which can be found by searching for `sympy_deprecation_warning` in the SymPy codebase

## Release notes entry

In the pull request, document the breaking change in the release notes section with **BREAKING CHANGE**.

Once the PR is merged, you should also add it to the “Backwards compatibility breaks and deprecations” section of the release notes for the upcoming release. This needs to be done manually, in addition to the change from the bot. See <https://github.com/sympy/sympy/wiki/Writing-Release-Notes#backwards-compatibility-breaks-and-deprecations>

Whenever a deprecated functionality is removed entirely after its deprecation period, this also needs to be marked as a **BREAKING CHANGE** and added to the “Backwards compatibility breaks and deprecations” section of the release notes.

This implementation detail is that Python provides no reliable method to determine that a chained inequality is being built. Chained comparison operators are evaluated pairwise, using “and” logic (see <http://docs.python.org/reference/expressions.html#not-in>). This is done in an efficient way, so that each object being compared is only evaluated once and the comparison can short-circuit. For example,  $1 > 2 > 3$  is evaluated by Python as  $(1 > 2)$  and  $(2 > 3)$ . The and operator coerces each side into a bool, returning the object itself when it short-circuits. The bool of the `-Than` operators will raise `TypeError` on purpose, because SymPy cannot determine the mathematical ordering of symbolic expressions. Thus, if we were to compute  $x > y > z$ , with  $x$ ,  $y$ , and  $z$  being Symbols, Python converts the statement (roughly) into these steps:

  - (1)  $x > y > z$
  - (2)  $(x > y)$  and  $(y > z)$
  - (3) `GreaterThanObject` and  $(y > z)$
  - (4) `GreaterThanObject.__bool__()` and  $(y > z)$
  - (5) `TypeError`

Because of the and added at step 2, the statement gets turned into a weak ternary statement, and the first object’s `__bool__` method will raise `TypeError`. Thus, creating a chained inequality is not possible.

In Python, there is no way to override the and operator, or to control how it short circuits, so it is impossible to make something like  $x > y >$

z work. There was a PEP to change this, [PEP 335](#), but it was officially closed in March, 2012.

- [R132] This implementation detail is that Python provides no reliable method to determine that a chained inequality is being built. Chained comparison operators are evaluated pairwise, using “and” logic (see <http://docs.python.org/reference/expressions.html#not-in>). This is done in an efficient way, so that each object being compared is only evaluated once and the comparison can short-circuit. For example,  $1 > 2 > 3$  is evaluated by Python as  $(1 > 2)$  and  $(2 > 3)$ . The and operator coerces each side into a bool, returning the object itself when it short-circuits. The bool of the -Than operators will raise TypeError on purpose, because SymPy cannot determine the mathematical ordering of symbolic expressions. Thus, if we were to compute  $x > y > z$ , with x, y, and z being Symbols, Python converts the statement (roughly) into these steps:

- (1)  $x > y > z$
- (2)  $(x > y)$  and  $(y > z)$
- (3) (GreaterThanObject) and  $(y > z)$
- (4) (GreaterThanObject.\_\_bool\_\_()) and  $(y > z)$
- (5) TypeError

Because of the and added at step 2, the statement gets turned into a weak ternary statement, and the first object’s \_\_bool\_\_ method will raise TypeError. Thus, creating a chained inequality is not possible.

In Python, there is no way to override the and operator, or to control how it short circuits, so it is impossible to make something like  $x > y > z$  work. There was a PEP to change this, [PEP 335](#), but it was officially closed in March, 2012.

- [R133] This implementation detail is that Python provides no reliable method to determine that a chained inequality is being built. Chained comparison operators are evaluated pairwise, using “and” logic (see <http://docs.python.org/reference/expressions.html#not-in>). This is done in an efficient way, so that each object being compared is only evaluated once and the comparison can short-circuit. For example,  $1 > 2 > 3$  is evaluated by Python as  $(1 > 2)$  and  $(2 > 3)$ . The and operator coerces each side into a bool, returning the object itself when it short-circuits.
